A

MATHEMATICAL AND PHILOSOPHICAL DICTIONARY.

VOL. II.——PART I.

A

MATHEMATICAL AND PHILOSOPHICAL

DICTIONARY:

CONTAINING

AN EXPLANATION OF THE TERMS, AND AN ACCOUNT OF THE SEVERAL SUBJECTS,

COMPRIZED UNDER THE HEADS

MATHEMATICS, ASTRONOMY, AND PHILOSOPHY

BOTH NATURAL AND EXPERIMENTAL:

WITH AN

HISTORICAL ACCOUNT OF THE RISE, PROGRESS, AND PRESENT STATE OF THESE SCIENCES:

ALSO

MEMOIRS OF THE LIVES AND WRITINGS OF THE MOST EMINENT AUTHORS,

BOTH ANCIENT AND MODERN,

WHO BY THEIR DISCOVERIES OR IMPROVEMENTS HAVE CONTRIBUTED TO THE ADVANCEMENT OF THEM.

IN TWO VOLUMES.

WITH MANY CUTS AND COPPER-PLATES.

52003 cu.

BY CHARLES HUTTON, LL.D. F.R.S.
OF LONDON AND EDINBURGH, AND OF THE PHILOSOPHICAL SOCIETIES OF HAARLEM AND AMERICA;
AND PROFESSOR OF MATHEMATICS IN THE ROYAL MILITARY ACADEMY, WOOLWICH.

VOL. II.

LONDON:
PRINTED FOR J. JOHNSON, IN ST. PAUL'S CHURCH-YARD; AND G. G. AND J. ROBINSON,
IN PATERNOSTER-ROW.

KEILL (Dr. JOHN), an eminent mathematician and philoſopher, was born at Edinburgh in 1671, and ſtudied in the univerſity of that city. His genius leading him to the mathematics, he made a great progreſs under David Gregory the profeſſor there, who was one of the firſt that had embraced and publicly taught the Newtonian philoſophy. In 1694 he followed his tutor to Oxford, where, being admitted of Baliol College, he obtained one of the Scotch exhibitions in that college. It is ſaid he was the firſt who taught Newton's principles by the experiments on which they are founded: and this it ſeems he did by an apparatus of inſtruments of his own providing; by which means he acquired a great reputation in the univerſity. The firſt public ſpecimen he gave of his ſkill in mathematical and philoſophical knowledge, was his *Examination of Dr. Burnet's Theory of the Earth; with Remarks on Mr. Whiſton's New Theory;* which appeared in 1698. Theſe theories were defended by their reſpective authors; which drew from him, in 1699, *An Examination of the Reflections on the Theory of the Earth*, together with *A Defence of the Remarks on Mr. Whiſton's New Theory.* Dr. Burnet was a man of great humanity, moderation, and candour; and it was therefore ſuppoſed that Keill had treated him too roughly, conſidering the great diſparity of years between them. Keill however left the doctor in poſſeſſion of that which has ſince been thought the great characteriſtic and excellence of his work; and though he diſclaimed him as a philoſopher, yet allowed him to be a man of a fine imagination. "Perhaps, ſays he, many of his readers will be ſorry to be undeceived about his theory; for, as I believe never any book was fuller of miſtakes and errors in philoſophy, ſo none ever abounded with more beautiful ſcenes and ſurpriſing images of nature. But I write only to thoſe who might expect to find a true philoſophy in it: they who read it as an ingenious romance, will ſtill be pleaſed with their entertainment."

The year following, Dr. Millington, Sedleian profeſſor of natural philoſophy in Oxford, who had been appointed phyſician to king William, ſubſtituted Keill as his deputy, to read the lectures in the public ſchool. This office he diſcharged with great reputation; and, the term of enjoying the Scotch exhibition at Baliol-college now expiring, he accepted an invitation from Dr. Aldrich, dean of Chriſt-church, to reſide there.

In 1701, he publiſhed his celebrated treatiſe, intitled, *Introductio ad Veram Phyſicam*, which is ſuppoſed to be the beſt and moſt uſeful of all his performances. The firſt edition of this book contained only fourteen lectures; but to the ſecond, in 1705, he added two more. This work was deſervedly eſteemed, both at home and abroad, as the beſt introduction to the Principia, or the new mechanical philoſophy, and was reprinted in different places; alſo a new edition in Engliſh was printed at London in 1736, at the inſtance of M. Maupertuis, who was then in England.

Being made Fellow of the Royal Society, he publiſhed, in the Philoſ. Tranſ. 1708, a paper on the Laws of Attraction, and its phyſical principles: and being offended at a paſſage in the *Acta Eruditorum* of Leipſic, where Newton's claim to the firſt invention of the me-

thod of Fluxions was called in queſtion, he warmly vindicated that claim againſt Leibnitz. In 1709 he went to New-England as treaſurer of the Palatines; and ſoon after his return in 1710, he was choſen Savilian profeſſor of aſtronomy at Oxford. In 1711, being attacked by Leibnitz, he entered the liſts with that mathematician, in the diſpute concerning the invention of Fluxions. Leibnitz wrote a letter to Dr. Hans Sloane, then ſecretary to the Royal Society, requiring Keill, in effect, to make him ſatisfaction for the injury he had done him in his paper relating to the paſſage in the *Acta Eruditorum:* he proteſted, that he was far from aſſuming to himſelf Newton's method of Fluxions; and therefore deſired that Keill might be obliged to retract his falſe aſſertion. On the other hand, Keill deſired that he might be permitted to juſtify what he had aſſerted. He made his defence to the approbation of Newton, and other members of the Society. A copy of this was ſent to Leibnitz; who, in a ſecond letter, remonſtrated ſtill more loudly againſt Keill's want of candour and ſincerity; adding, that it was not fit for one of his age and experience to engage in a diſpute with an upſtart, who acted without any authority from Newton, and deſiring that the Royal Society would enjoin him ſilence. Upon this, a ſpecial committee was appointed; who, after examining the facts, concluded their report with "reckoning Mr. Newton the inventor of Fluxions; and that Mr. Keill, in aſſerting the ſame, had been no ways injurious to Mr. Leibnitz." The whole proceedings upon this matter may be ſeen in Collins's *Commercium Epiſtolicum*, with many valuable papers of Newton, Leibnitz, Gregory, and other mathematicians. In the mean time Keill behaved himſelf with great firmneſs and ſpirit; which he alſo ſhewed afterwards in a Latin epiſtle, written in 1720, to Bernoulli, mathematical profeſſor at Baſil, on account of the ſame uſage ſhewn to Newton: in the title-page of which he put the arms of Scotland, viz, a Thiſtle, with this motto, *Nemo me impune laceſſit.*

About the year 1711, ſeveral objections being urged againſt Newton's philoſophy, in ſupport of Des Cartes's notions of a plenum, Keill publiſhed a paper in the Philoſ. Tranſ. on the Rarity of Matter, and the Tenuity of its Compoſition. But while he was engaged in this diſpute, queen Anne was pleaſed to appoint him her Decipherer; and he continued in that place under king George the Firſt till the year 1716. The univerſity of Oxford conferred on him the degree of M D. in 1713; and, two years after, he publiſhed an edition of Commandine's Euclid, with additions of his own. In 1718 he publiſhed his *Introductio ad Veram Aſtronomiam:* which was afterwards, at the requeſt of the ducheſs of Chandos, tranſlated by himſelf into Engliſh; and, with ſeveral emendations, publiſhed in 1721, under the title of *An Introduction to True Aſtronomy*, &c. This was his laſt gift to the public; being this ſummer ſeized with a violent fever, which terminated his life Sept. 1, in the 50th year of his age.

His papers in the Philoſ. Tranſ. above alluded to, are contained in volumes 26 and 29.

KEILL (Dr. *James*), an eminent phyſician and philoſopher, and younger brother of Dr. John Keill above mentioned, was alſo born in Scotland, in 1673. Having travelled abroad, on his return he read lectures on Anatomy with great applauſe in the univerſities of Oxford and Cambridge, by the latter of which he had the degree of M. D. conferred upon him. In 1703 he ſettled at Northampton as a phyſician, where he died of a cancer in the mouth in 1719. His publications are

1. An Engliſh tranſlation of Lemery's Chemiſtry.

2. On Animal Secretion, the quantity of Blood in the Human Body, and on Muſcular Motion.

3. A treatiſe on Anatomy.

4. Several pieces in the Philoſ. Tranſ. volumes 25 and 30.

KEPLER (JOHN), a very eminent aſtronomer and mathematician, was born at Wiel, in the county of Wirtemberg, in 1571. He was the diſciple of Mæſtlinus, a learned mathematician and aſtronomer, of whom he learned thoſe ſciences, and became afterwards profeſſor of them to three ſucceſſive emperors, viz. Matthias, Rudolphus, and Ferdinand the 2d.

To this ſagacious philoſopher we owe the firſt diſcovery of the great laws of the planetary motions, viz. that the planets deſcribe areas that are always proportional to the times; that they move in elliptical orbits, having the ſun in one focus; and that the ſquares of their periodic times, are proportional to the cubes of their mean diſtances; which are now generally known by the name of Kepler's Laws. But as this great man ſtands as it were at the head of the modern reformed aſtronomy, he is highly deſerving of a pretty large account, which we ſhall extract chiefly from the words of that great mathematician Mr. Maclaurin.

Kepler had a particular paſſion for finding analogies and harmonies in nature, after the manner of the Pythagoreans and Platoniſts; and to this diſpoſition we owe ſuch valuable diſcoveries, as are more than ſufficient to excuſe his conceits. Three things, he tells us, he anxiouſly ſought to find out the reaſon of, from his early youth; viz, Why the planets were 6 in number? Why the dimenſions of their orbits were ſuch as Copernicus had deſcribed from obſervations? And what was the analogy or law of their revolutions? He ſought for the reaſons of the two firſt of theſe, in the properties of numbers and plane figures, without ſucceſs. But at length reflecting, that while the plane regular figures may be infinite in number, the regular ſolids are only five, as Euclid had long ago demonſtrated: he imagined, that certain myſteries in nature might correſpond with this remarkable limitation inherent in the eſſences of things; and the rather, as he found that the Pythagoreans had made great uſe of thoſe five regular ſolids in their philoſophy. He therefore endeavoured to find ſome relation between the dimenſions of theſe ſolids and the intervals of the planetary ſpheres; thus, imagining that a cube, inſcribed in the ſphere of Saturn, would touch by its ſix planes the ſphere of Jupiter; and that the other four regular ſolids in like manner fitted the intervals that are between the ſpheres of the other planets: he became perſuaded that this was the true reaſon why the primary planets were preciſely ſix in number, and that the author of the world had determined their diſtances from the ſun, the centre of the ſyſtem, from a regard to this analogy. Being thus poſſeſſed, as he thought, of the grand ſecret of the Pythagoreans, and greatly pleaſed with his diſcovery, he publiſhed it in 1596, under the title of *Myſterium Coſmographicum;* and was for ſome time ſo charmed with it, that he ſaid

he

he would not give up the honour of having invented what was contained in that book, for the electorate of Saxony.

Kepler ſent a copy of this book to Tycho Brahe, who did not approve of thoſe abſtract ſpeculations concerning the ſyſtem of the world, but wrote to Kepler, firſt to lay a ſolid foundation in obſervations, and then, by aſcending from them, to endeavour to come at the cauſes of things. Tycho however, pleaſed with his genius, was very deſirous of having Kepler with him to aſſiſt him in his labours: and having ſettled, under the protection of the emperor, in Bohemia, where he paſſed the laſt years of his life, after having left his native country on ſome ill uſage, he prevailed upon Kepler to leave the univerſity of Gratz, and remove into Bohemia, with his family and library, in the year 1600. But Tycho dying the next year, the arranging the obſervations devolved upon Kepler, and from that time he had the title of Mathematician to the Emperor all his life, and gained continually more and more reputation by his works. The emperor Rudolph ordered him to finiſh the tables of Tycho Brahe, which were to be called the *Rudolphine Tables*. Kepler applied diligently to the work; but unhappy are thoſe learned men who depend upon the good-humour of the intendants of the finances; the treaſurers were ſo ill-affected towards our author, that he could not publiſh theſe tables till 1627. He died at Ratiſbon, in 1630, where he was ſoliciting the payment of the arrears of his penſion.

Kepler made many important diſcoveries from Tycho's obſervations, as well as his own. He found, that aſtronomers had erred, from the firſt riſe of the ſcience, in aſcribing always circular orbits and uniform motions to the planets; that, on the contrary, each of them moves in an ellipſis which has one of its foci in the ſun: that the motion of each is really unequable, and varies ſo, that a ray ſuppoſed to be always drawn from the planet to the ſun deſcribes equal areas in equal times.

It was ſome years later before he diſcovered the analogy there is between the diſtances of the ſeveral planets from the ſun, and the periods in which they complete their revolutions. He eaſily ſaw, that the higher planets not only moved in greater circles, but alſo more ſlowly than the nearer ones; ſo that, on a double account, their periodic times were greater. Saturn, for example, revolves at the diſtance from the ſun $9\frac{1}{2}$ times greater than the earth's diſtance from it; and the circle deſcribed by Saturn is in the ſame proportion: but as the earth revolves in one year, ſo, if their velocities were equal, Saturn ought to revolve in 9 years and a half; whereas the periodic time of Saturn is about 29 years. The periodic times of the planets increaſe, therefore, in a greater proportion than their diſtances from the ſun: but yet not in ſo great a proportion as the ſquares of thoſe diſtances; for if that were the law of the motions, (the ſquare of $9\frac{1}{2}$ being $90\frac{1}{4}$), the periodic time of Saturn ought to be above 90 years. A mean proportion between that of the diſtances of the planets, and that of the ſquares of thoſe diſtances, is the true proportion of the periodic times; as the mean between $9\frac{1}{2}$ and its ſquare $90\frac{1}{4}$, gives the periodic time of Saturn in years. Kepler, after having committed ſeveral miſtakes in determining this analogy, hit upon it at laſt, May the 15, 1618; for he is ſo particular as to mention the preciſe day when he found that "The ſquares of the periodic times were always in the ſame proportion as the cubes of their mean diſtances from the ſun."

When Kepler ſaw, according to better obſervations, that his diſpoſition of the five regular ſolids among the planetary ſpheres, was not agreeable to the intervals between their orbits, he endeavoured to diſcover other ſchemes of harmony. For this purpoſe, he compared the motions of the ſame planet at its greateſt and leaſt diſtances, and of the different planets in their ſeveral orbits, as they would appear viewed from the ſun; and here he fancied that he found a ſimilitude to the diviſions of the octave in muſic. Theſe were the dreams of this ingenious man, which he was ſo fond of, that, hearing of the diſcovery of four new planets (the ſatellites of Jupiter) by Galileo, he owns that his firſt reflections were from a concern how he could ſave his favourite ſcheme, which was threatened by this addition to the number of the planets. The ſame attachment led him into a wrong judgment concerning the ſphere of the fixed ſtars: for being obliged, by his doctrine, to allow a vaſt ſuperiority to the ſun in the univerſe, he reſtrains the fixed ſtars within very narrow limits. Nor did he conſider them as ſuns, placed in the centres of their ſeveral ſyſtems, having planets revolving round them; as the other followers of Copernicus have concluded them to be, from their having light in themſelves, from their immenſe diſtances, and from the analogy of nature. Not contented with theſe harmonies, which he had learned from the obſervations of Tycho, he gave himſelf the liberty to imagine ſeveral other analogies, that have no foundation in nature, and are overthrown by the beſt obſervations. Thus from the opinions of Kepler, though moſt juſtly admired, we are taught the danger of eſpouſing principles, or hypotheſes, borrowed from abſtract ſciences, and of applying them, with ſuch freedom, to natural enquiries.

A more recent inſtance of this fondneſs, for diſcovering analogies between matters of abſtract ſpeculation, and the conſtitution of nature, we find in Huygens, one of the greateſt geometricians and aſtronomers any age has produced: when he had diſcovered that ſatellite of Saturn, which from him is ſtill called the Huygenian ſatellite, this, with our moon, and the four ſatellites of Jupiter, completed the number of ſix ſecondary planets then diſcovered in the ſyſtem; and becauſe the number of primary planets was alſo ſix, and this number is called by mathematicians a perfect number (being equal to the ſum of its aliquot parts, 1, 2, 3,) Huygens was hence induced to believe that the number of the planets was complete, and that it was in vain to look for any more. This is not mentioned to leſſen the credit of this great man, who never perhaps reaſoned in ſuch a manner on any other occaſion; but only to ſhew, by another inſtance, how ill-grounded reaſonings of this kind have always proved. For, not long after, the celebrated Caſſini diſcovered four more ſatellites about Saturn, not to mention the two more that have lately been diſcovered to that planet by Dr. Herſchel, with another new primary planet and its two ſatellites, beſides many others, of both ſorts, as yet unknown, which poſſibly may belong to our ſyſtem. The ſame Caſſini having found that the analogy, diſcovered by Kepler, between the periodic times and the diſtances from the centre, takes place in

the leſſer ſyſtems of Jupiter and Saturn, as well as in the great ſolar ſyſtem; his obſervations overturned that groundleſs analogy which had been imagined between the number of the planets, both primary and ſecondary, and the number ſix: but eſtabliſhed, at the ſame time, that harmony in their motions, which will afterwards appear to flow from one real principle extended over the univerſe.

But to return to Kepler; his great ſagacity, and continual meditations on the planetary motions, ſuggeſted to him ſome views of the true principles from which theſe motions flow. In his preface to the Commentaries concerning the planet Mars, he ſpeaks of gravity as of a power that was mutual between bodies, and tells us, that the earth and moon tend towards each other, and would meet in a point, ſo many times nearer to the earth than to the moon, as the earth is greater than the moon, if their motions did not hinder it. He adds, that the tides ariſe from the gravity of the waters towards the moon. But not having notions ſufficiently juſt of the laws of motion, it ſeems he was not able to make the beſt uſe of theſe thoughts; nor does it appear that he adhered to them ſteadily, ſince in his Epitome of Aſtronomy, publiſhed many years after, he propoſes a phyſical account of the planetary motions, derived from different principles.

He ſuppoſes, in that treatiſe, that the motion of the ſun on his axis, is preſerved by ſome inherent vital principle; that a certain virtue, or immaterial image of the ſun, is diffuſed with his rays into the ambient ſpaces, and, revolving with the body of the ſun on his axis, takes hold of the planets, and carries them along with it in the ſame direction; like as a loadſtone turned round near a magnetic needle, makes it turn round at the ſame time. The planet, according to him, by its inertia, endeavours to continue in its place, and the action of the ſun's image and this inertia are in a perpetual ſtruggle. He adds, that this action of the ſun, like his light, decreaſes as the diſtance increaſes; and therefore moves the ſame planet with greater celerity when nearer the ſun, than at a greater diſtance. To account for the planet's approaching towards the ſun as it deſcends from the aphelion to the perihelion, and receding from the ſun while it aſcends to the aphelion again, he ſuppoſes that the ſun attracts one part of each planet, and repels the oppoſite part; and that the part attracted is turned towards the ſun in the deſcent, and the other towards the ſun in the aſcent. By ſuppoſitions of this kind, he endeavoured to account for all the other varieties of the celeſtial motions.

But, now that the laws of motion are better known than in Kepler's time, it is eaſy to ſhew the fallacy of every part of this account of the planetary motions. The planet does not endeavour to ſtop in conſequence of its inertia, but to perſevere in its motion in a right line. An attractive force makes it deſcend from the aphelion to the perihelion in a curve concave towards the ſun: but the repelling force, which he ſuppoſed to begin at the perihelion, would cauſe it to aſcend in a figure convex towards the ſun. There will be occaſion to ſhew afterwards, from Sir Iſaac Newton, how an attraction or gravitation towards the ſun, alone produces the effects, which, according to Kepler, required both an attractive and repelling force; and that the virtue which he aſcribed to the ſun's image, propagated into the planetary regions, is unneceſſary, as it could be of no uſe for this effect, though it were admitted. For now his own prophecy, with which he concludes his book, is verified; where he tells us, that "the diſcovery of ſuch things was reſerved for the ſucceeding ages, when the author of nature would be pleaſed to reveal theſe myſteries."

The works of this celebrated author are many and valuable; as,

1. His *Coſmographical Myſtery*, in 1596.
2. *Optical Aſtronomy*, in 1604.
3. *Account of a New Star in Sagittarius*, 1605.
4. *New Aſtronomy*; or, *Celeſtial Phyſics*, in Commentaries on the planet Mars.
5. *Diſſertations*; with the *Nuncius Sidereus* of Galileo, 1610.
6. *New Gauging of Wine Caſks*, 1615. Said to be written on occaſion of an erroneous meaſurement of the wine at his marriage by the revenue officer.
7. *New Ephemerides*, from 1617 to 1620.
8. *Copernican Syſtem*, three firſt books of the, 1618.
9. *Harmony of the World*; and three books of *Comets*, 1619.
10. *Coſmographical Myſtery*, 2d edit. with Notes, 1621.
11. *Copernican Aſtronomy*; the three laſt books, 1622.
12. *Logarithms*, 1624; and the *Supplement*, in 1625.
13. His *Aſtronomical Tables*, called the *Rudolphine Tables*, in honour of the emperor Rudolphus, his great and learned patron, in 1627.
14. *Epitome of the Copernican Aſtronomy*, 1635.

Beſide theſe, he wrote ſeveral pieces on various other branches, as *Chronology*, *Geometry of Solids*, *Trigonometry*, and an excellent treatiſe of *Dioptrics*, for that time.

KEPLER'S LAWS, are thoſe laws of the planetary motions diſcovered by Kepler. Theſe diſcoveries in the mundane ſyſtem, are commonly accounted two, viz. 1ſt, That the planets deſcribe about the ſun, areas that are proportional to the times in which they are deſcribed, namely, by a line connecting the ſun and planet; and 2d, That the ſquares of the times of revolution, are as the cubes of the mean diſtances of the planets from the ſun. Kepler diſcovered alſo that the orbits of the planets are elliptical.

Theſe diſcoveries of Kepler, however, were only found out by many trials, in ſearching among a great number of aſtronomical obſervations and revolutions, what rules and laws were found to obtain. On the other hand, Newton has demonſtrated, *a priori*, all theſe laws, ſhewing that they muſt obtain in the mundane ſyſtem, from the laws of gravitation and centripetal force; viz, the firſt of theſe laws reſulting from a centripetal force urging the planets towards the ſun, and the 2d, from the centripetal force being in an inverſe ratio of the ſquare of the diſtance. And the elliptic form of the orbits, from a projectile force regulated by a centripetal one.

KEPLER'S *Problem*, is the determining the true from the mean anomaly of a planet, or the determining its place, in its elliptic orbit, anſwering to any given time; and ſo named from the celebrated aſtronomer Kepler, who firſt propoſed it. See ANOMALY.

The general ſtate of the problem is this: To find the poſition of a right line, which, paſſing through one of the foci of an ellipſis, ſhall cut off an area which ſhall be in any given proportion to the whole area of the ellipſis; which reſults from this property, that ſuch a line ſweeps areas that are proportional to the times.

Many ſolutions have been given of this problem, ſome direct and geometrical, others not: viz, by Kepler, Bulliald, Ward, Newton, Keill, Machin, &c. See Newton's Princip. lib. 1. prop. 31, Keill's Aſtron. Lect. 23, Philoſ. Tranſ. abr. vol. 8. pa. 73, &c.

In the laſt of theſe places, Mr. Machin obſerves, that many attempts have been made at different times, but with no great ſucceſs, towards the ſolution of the problem propoſed by Kepler: To divide the area of a ſemicircle into given parts, by a line drawn from a given point in the diameter, in order to find an univerſal rule for the motion of a body in an elliptic orbit. For among the ſeveral methods offered, ſome are only true in ſpeculation, but are really of no ſervice; others are not different from his own, which he judged improper. And as to the reſt, they are all ſo limited and confined to particular conditions and circumſtances, as ſtill to leave the problem in general untouched. To be more particular; it is evident, that all conſtructions by mechanical curves are ſeeming ſolutions only, but in reality unapplicable; that the roots of infinite ſeries are, on account of their known limitations in all reſpects, ſo far from being ſufficient rules, that they ſerve for little more than exerciſes in a method of calculation. And then, as to the univerſal method, which proceeds by a continued correction of the errors of a falſe poſition, it is no method of ſolution at all in itſelf; becauſe, unleſs there be ſome antecedent rule or hypotheſis to begin the operation (as ſuppoſe that of an uniform motion about the upper focus, for the orbit of a planet; or that of a motion in a parabola for the perihelion part of the orbit of a comet, or ſome other ſuch), it would be impoſſible to proceed one ſtep in it. But as no general rule has ever yet been laid down, to aſſiſt this method, ſo as to make it always operate, it is the ſame in effect as if there were no method at all. And accordingly in experience it is found, that there is no rule now ſubſiſting but what is abſolutely uſeleſs in the elliptic orbits of comets; for in ſuch caſes there is no other way to proceed but that which was uſed by Kepler: to compute a table for ſome part of the orbit, and in it examine if the time to which the place is required, will fall out any where in that part. So that, upon the whole, it appears evident, that this problem, contrary to the received opinion, has never yet been advanced one ſtep towards its true ſolution.

Mr. Machin then proceeds to give his own ſolution of this problem, which is particularly neceſſary in orbits of a great excentricity; and he illuſtrates his method by examples for the orbits of Venus, of Mercury, of the comet of the year 1682, and of the great comet of the year 1680, ſufficiently ſhewing the univerſality of the method.

KEY, in Muſic, is a certain fundamental note, or tone, to which the whole piece, be it concerto, ſonata, cantata, &c, is accommodated; and with which it uſually begins, but always ends.

KEYS denote alſo, in an organ, harpſichord, &c, the pieces of wood or ivory which are ſtruck by the fingers, in playing upon the inſtrument.

KEYSTONE, the middle vouſſoir, or the arch ſtone in the top, or immediately over the centre of an arch.—The length of the keyſtone, or thickneſs of the archivolt at top, is allowed by the beſt architects, to be about the 15th or 16th part of the ſpan.

KILDERKIN, a kind of liquid meaſure, containing two firkins, or 18 gallons, beer-meaſure, or 16 ale-meaſure.

KING-*piece*, or KING-*poſt*, is a piece of timber ſet upright in the middle, between two principal rafters, and having ſtruts or braces going from it to the middle of each rafter.

KIRCH (CHRISTIAN FREDERIC), of Berlin, a celebrated aſtronomer, was born at Guben in 1694. He acquired great reputation in the obſervatories of Dantzic and Berlin. Godfrey Kirch his father, and Mary his mother, alſo acquired conſiderable reputation by their aſtronomical obſervations. This family correſponded with all the learned ſocieties of Europe, and their aſtronomical works are in great repute.

KIRCHER (ATHANASIUS), a famous philoſopher and mathematician, was born at Fulde in 1601. He entered into the ſociety of the Jeſuits in 1618, and taught philoſophy, mathematics, the Hebrew and Syriac Languages, in the univerſity of Wirtſburg, with great applauſe, till the year 1631. He retired to France on account of the ravages committed by the Swedes in Franconia, and lived ſome time at Avignon. He was afterwards called to Rome, where he taught mathematics in the Roman college, collected a rich cabinet of machines and antiquities, and died in 1680, in the 80th year of his age.

The quantity of his works is immenſe, amounting to 22 volumes in folio, 11 in quarto, and three in octavo; enough to employ a man for a great part of his life even to tranſcribe them. Moſt of them are rather curious than uſeful; many of them viſionary and fanciful; and it is not to be wondered at, if they are not always accompanied with the greateſt exactneſs and preciſion. The principal of them are,

1. *Præluſiones Magneticæ.*
2. *Primitiæ Gnomonicæ Catoptricæ.*
3. *Ars magna Lucis et Umbræ.*
4. *Muſurgia Univerſalis.*
5. *Obeliſcus Pamphilius.*
6. *Oedipus Ægyptiacus;* 4 volumes folio.
7. *Itinerarium Extaticum.*
8. *Obeliſcus Ægyptiacus;* 4 volumes folio.
9. *Mundus Subterraneus.*
10. *China Illuſtrata.*

KNOT, a tye, or complication of a rope, cord, or ſtring, or of the ends of two together. There are divers ſorts of knots uſed for different purpoſes, which may be explained by ſhewing the figures of them open, or undrawn, thus. 1. Fig. 1, plate xiii. is a *Thumb knot*. This is the ſimpleſt of all. It is uſed to tye at the end of a rope, to prevent its opening out: it is alſo uſed by taylors &c. at the end of their thread.

Fig. 2, a *Loop knot*. Uſed to join pieces of rope &c. together.

Fig. 3, a *Draw knot*, which is the ſame as the laſt; only one end or both return the ſame way back, as *a b c d*.

a b c d. By drawing at *a*, the part *b c d* comes through, and the knot is looſed.

Fig. 4, a *Ring knot*. This ſerves alſo to join pieces of cord &c together.

Fig. 5 is another knot for tying cords together. This is uſed when any cord is often to be looſed.

Fig. 6, a *Running knot*, to draw any thing cloſe. By pulling at the end *a*, the cord is drawn through the loop *b*, and the part *c d* is drawn cloſe about a beam, &c.

Fig. 7 is another knot, to tye any thing to a poſt. And here the end may be put through as often as you pleaſe.

Fig. 8, a *Very ſmall knot*. A thumb knot is firſt made at the end of each piece, and then the end of the other is paſſed through it. Thus, the cord *a c* runs through the loop *d*, and *b d* through *c*; and then drawn cloſe by pulling at *a* and *b*. If the ends *e* and *f* be drawn, the knot will be looſed again.

Fig. 9, a *Fiſher's knot*, or *Water knot*. This is the ſame as the 4th, only the ends are to be put twice through the ring, which in the former was but once; and then drawn cloſe.

Fig. 10, a *Meſhing knot*, for nets; and is to be drawn cloſe.

Fig. 11, a *Barber's knot*, or a knot for cawls of wigs; and is to be drawn cloſe.

Fig. 12, a *Bowline knot*. When this is drawn cloſe, it makes a loop that will not ſlip, as fig. 7; and ſerves to hitch over any thing.

Fig. 13, a *Wale knot*, which is made with the three ſtrands of a rope, ſo that it cannot ſlip. When the rope is put through a hole, this knot keeps it from ſlipping through. When the three ſtrands are wrought round once or twice more, after the ſame manner, it is called *crowning*. By this means the knot is made larger and ſtronger. A thumb knot, N°. 1, may be applied to the ſame uſe as this.

KNOTS mean alſo the diviſions of the log line, uſed at ſea. Theſe are uſually 7 fathom, or 42 feet aſunder; but ſhould be 8⅓ fathom, or 50 feet. And then, as many knots as the log line runs out in half a minute, ſo many miles does the ſhip ſail in an hour; ſuppoſing her to keep going at an equal rate, and allowing for yaws, leeway, &c.

KOENIG (SAMUEL), a learned philoſopher and mathematician, was a Swiſs by birth, and came early into eminence by his mathematical abilities. He was profeſſor of philoſophy and natural law at Franeker, and afterwards at the Hague, where he became alſo librarian to the Stadtholder, and to the Princeſs of Orange; and where he died in 1757.

The Academy of Berlin enrolled him among her members; but afterwards expelled him on the following occaſion. Maupertuis, the preſident, had inſerted in the volume of the Memoirs for 1746, a diſcourſe upon the Laws of Motion; which Koenig not only attacked, but alſo attributed the memoir to Leibnitz. Maupertuis, ſtung with the imputation of plagiariſm, engaged the Academy of Berlin to call upon him for his proof; which Koenig failing to produce, he was ſtruck out of the academy. All Europe was intereſted in the quarrel which this occaſioned between Koenig and Maupertuis. The former appealed to the public; and his appeal, written with the animation of reſentment, procured him many friends. He was author of ſome other works, and had the character of being one of the beſt mathematicians of the age.

L.

LABEL, a long thin braſs ruler, with a ſmall ſight at one end, and a central hole at the other; commonly uſed with a tangent-line on the edge of a circumferentor, to take altitudes, and other angles.

LACERTA, *Lizard*, one of the new conſtellations of the northern hemiſphere, added by Hevelius to the 48 old ones, near Cepheus and Caſſiopeia.

This conſtellation contains, in Hevelius's catalogue 10 ſtars, and in Flamſteed's 16.

LACUNAR, an arched roof or cieling; more eſpecially the planking or flooring above the porticos.

LADY-*Day*, the 25th of March, being the Annunciation of the Holy Virgin.

LAGNY (THOMAS FANTET *de*), an eminent French mathematician, was born at Lyons. Fournier's Euclid, and Pelletier's Algebra, by chance falling in his way, developed his genius for the mathematics. It was in vain that his father deſigned him for the law; he went to Paris to deliver himſelf wholly up to the ſtudy of his favourite ſcience. In 1697, the Abbé Bignon, protector-general of letters, got him appointed profeſſor-royal of Hydrography at Rochfort. Soon after, the duke of Orleans, then regent of France, fixed him at Paris, and made him ſub-director of the General Bank, in which he loſt the greateſt part of his fortune in the failure of the Bank. He had been received into the ancient academy in 1696; upon the renewal of which he was named Aſſociate-geometrician in 1699, and penſioner in 1723. After a life ſpent in cloſe application, he died, April 12, 1734.

In the laſt moments of his life, and when he had loſt all knowledge of the perſons who ſurrounded his

bed, one of them, through curiofity, aſked him, what is the ſquare of 12? To which he immediately replied, and without ſeeming to know that he gave any anſwer, 144.

De Lagny particularly excelled in arithmetic, algebra, and geometry, in which he made many improvements and diſcoveries. He, as well as Leibnitz, invented a binary arithmetic, in which only two figures are concerned. He rendered much eaſier the reſolution of algebraic equations, eſpecially the irreducible caſe in cubic equations; and the numeral reſolution of the higher powers, by means of ſhort approximating theorems.—He delivered the meaſures of angles in a new ſcience, called *Goniometry*; in which he meaſured angles by a pair of compaſſes, without ſcales, or tables, to great exactneſs; and thus gave a new appearance to trigonometry.—*Cyclometry*, or the meaſure of the circle, was alſo an object of his attention; and he calculated, by means of infinite ſeries, the ratio of the circumference of a circle to its diameter, to 120 places of figures.—He gave a general theorem for the tangents of multiple arcs. With many other curious or uſeful improvements, which are found in the great multitude of his papers, that are printed in the different volumes of the Memoirs of the Academy of Sciences, viz, in almoſt every volume, from the year 1699, to 1729.

LAKE, a collection of water, incloſed in the cavity of ſome inland place, of a conſiderable extent and depth. As the Lake of Geneva, &c.

LAMMAS-Day, the 1ſt of Auguſt; ſo called, according to ſome, becauſe lambs then grow out of ſeaſon, as being too large. Others derive it from a Saxon word, ſignifying *loaf-maſs*, becauſe on that day our forefathers made an offering of bread prepared with new wheat.

It is celebrated by the Romiſh church in memory of St. Peter's impriſonment.

LAMPÆDIAS, a kind of bearded comet, reſembling a burning lamp, being of ſeveral ſhapes; for ſometimes its flame or blaze runs tapering upwards like a ſword, and ſometimes it is double or treble pointed.

LANDEN (John), an eminent mathematician, was born at Peakirk, near Peterborough in Northamptonſhire, in January 1719. He became very early a proficient in the mathematics, for we find him a very reſpectable contributor to the Ladies Diary in 1744; and he was ſoon among the foremoſt of thoſe who then contributed to the ſupport of that ſmall but valuable publication, in which almoſt every Engliſh mathematician who has arrived at any degree of eminence for the beſt part of this century, has contended for fame at one time or other of his life. Mr. Landen continued his contributions to it at times, under various ſignatures, till within a few years of his death.

It has been frequently obſerved, that the hiſtories of literary men conſiſt chiefly of the hiſtory of their writings; and the obſervation was never more fully verified, than in the preſent article concerning Mr. Landen.

In the 48th volume of the Philoſophical Tranſactions, for the year 1754, Mr. Landen gave "An Inveſtigation of ſome theorems which ſuggeſt ſeveral very remarkable properties of the Circle, and are at the ſame time of conſiderable uſe in reſolving Fractions, the denominators of which are certain Multinomials, into more ſimple ones, and by that means facilitate the computation of Fluents." This ingenious paper was delivered to the Society by that eminent mathematician Thomas Simpſon of Woolwich, a circumſtance which will convey to thoſe who are not themſelves judges of it, ſome idea of its merit.

In the year 1755, he publiſhed a volume of about 160 pages, intitled *Mathematical Lucubrations*. The title to this publication was made choice of, as a means of informing the world, that the ſtudy of the mathematics was at that time rather the purſuit of his leiſure hours, than his principal employment: and indeed it continued to be ſo, during the greateſt part of his life; for about the year 1762 he was appointed agent to Earl Fitzwilliam, an employment which he reſigned only two years before his death. Theſe Lucubrations contain a variety of tracts relative to the rectification of curve lines, the ſummation of ſeries, the finding of fluents, and many other points in the higher parts of the mathematics.

About the latter end of the year 1757, or the beginning of 1758, he publiſhed propoſals for printing by ſubſcription, *The Reſidual Analyſis*, a new Branch of the Algebraic art: and in 1758 he publiſhed a ſmall tract, entitled *A Diſcourſe on the Reſidual Analyſis*; in which he reſolved a variety of problems, to which the method of fluxions had uſually been applied, by a mode of reaſoning entirely new: he alſo compared theſe ſolutions with others derived from the fluxionary method; and ſhewed that the ſolutions by his new method were commonly more natural and elegant than the fluxionary ones.

In the 51ſt volume of the Philoſophical Tranſactions, for the year 1760, he gave *A New Method of computing the Sums of a great number of Infinite Series*. This paper was alſo preſented to the Society by his ingenious friend the late Mr. Thomas Simpſon.

In 1764, he publiſhed the firſt book of *The Reſidual Analyſis*. In this treatiſe, beſides explaining the principles which his new analyſis was founded on, he applied it, in a variety of problems, to drawing tangents, and finding the properties of curve lines; to deſcribing their involutes and evolutes, finding the radius of curvature, their greateſt and leaſt ordinates, and points of contrary flexure; to the determination of their cuſps, and the drawing of aſymptotes: and he propoſed, in a ſecond book, to extend the application of this new analyſis to a great variety of mechanical and phyſical ſubjects. The papers which were to have formed this book lay long by him; but he never found leiſure to put them in order for the preſs.

In the year 1766, Mr. Landen was elected a Fellow of the Royal Society. And in the 58th volume of the Philoſophical Tranſactions, for the year 1768, he gave *A ſpecimen of a New Method of comparing Curvilinear Areas*; by means of which many areas are compared, that did not appear to be comparable by any other method: a circumſtance of no ſmall importance in that part of natural philoſophy which relates to the doctrine of motion.

In the 60th volume of the ſame work, for the year 1770, he gave *Some New Theorems* for computing the Whole Areas of Curve Lines, where the Ordinates are expreſſed

expreſſed by Fractions of a certain form, in a more conciſe and elegant manner than had been done by Cotes, De Moivre, and others who had conſidered the ſubject before him.

In the 61ſt volume, for 1771, he has inveſtigated ſeveral new and uſeful theorems for computing certain fluents, which are aſſignable by arcs of the conic ſections. This ſubject had been conſidered before, both by Maclaurin and d'Alembert; but ſome of the theorems that were given by theſe celebrated mathematicians, being in part expreſſed by the difference between an hyperbolic arc and its tangent, and that difference being not directly attainable when the arc and its tangent both become infinite, as they will do when the whole fluent is wanted, although ſuch fluent be finite; theſe theorems therefore fail in theſe caſes, and the computation becomes impracticable without farther help. This defect Mr. Landen has removed, by aſſigning the *limit* of the difference between the hyperbolic arc and its tangent, while the point of contact is ſuppoſed to be removed to an infinite diſtance from the vertex of the curve. And he concludes the paper with a curious and remarkable property relating to pendulous bodies, which is deducible from thoſe theorems. In the ſame year he publiſhed *Animadverſions on Dr. Stewart's Computation of the Sun's Diſtance from the Earth.*

In the 65th volume of the Philoſophical Tranſactions, for 1775, he gave the inveſtigation of a General Theorem, which he had promiſed in 1771, for finding the Length of any Curve of a Conic Hyperbola by means of two Elliptic Arcs: and he obſerves, that by the theorems there inveſtigated, both the elaſtic curve and the curve of equable receſs from a given point, may be conſtructed in thoſe caſes where Maclaurin's elegant method fails.

In the 67th volume, for 1777, he gave "A New Theory of the Motion of bodies revolving about an axis in free ſpace, when that motion is diſturbed by ſome extraneous force, either percuſſive or accelerative." At that time he did not know that the ſubject had been treated by any perſon before him, and he conſidered only the motion of a ſphere, ſpheroid, and cylinder. After the publication of this paper however he was informed, that the doctrine of rotatory motion had been conſidered by d'Alembert; and upon procuring that author's *Opuſcules Mathematiques*, he there learned that d'Alembert was not the only one who had conſidered the matter before him; for d'Alembert there ſpeaks of ſome mathematician, though he does not mention his name, who, after reading what had been written on the ſubject, doubted whether there be any ſolid whatever, beſide the ſphere, in which any line, paſſing through the centre of gravity, will be a permanent axis of rotation. In conſequence of this, Mr. Landen took up the ſubject again; and though he did not then give a ſolution to the general problem, viz, "to determine the motions of a body of any form whatever, revolving without reſtraint about any axis paſſing through its centre of gravity," he fully removed every doubt of the kind which had been ſtarted by the perſon alluded to by d'Alembert, and pointed out ſeveral bodies which, under certain dimenſions, have that remarkable property. This paper is given, among many others equally curious, in a volume of *Memoirs*, which he publiſhed in the year 1780. That volume is alſo enriched with a very extenſive appendix, containing *Theorems for the Calculation of Fluents*; which are more complete and extenſive than thoſe that are found in any author before him.

In 1781, 1782, and 1783, he publiſhed three ſmall Tracts on the Summation of Converging Series; in which he explained and ſhewed the extent of ſome theorems which had been given for that purpoſe by De Moivre, Stirling, and his old friend Thomas Simpſon, in anſwer to ſome things which he thought had been written to the diſparagement of thoſe excellent mathematicians. It was the opinion of ſome, that Mr. Landen did not ſhew leſs mathematical ſkill in explaining and illuſtrating theſe theorems, than he has done in his writings on original ſubjects; and that the authors of them were as little aware of the extent of their own theorems, as the reſt of the world were before Mr. Landen's ingenuity made it obvious to all.

About the beginning of the year 1782, Mr. Landen had made ſuch improvements in his theory of Rotatory Motion, as enabled him, he thought, to give a ſolution of the general problem mentioned above; but finding the reſult of it to differ very materially from the reſult of the ſolution which had been given of it by d'Alembert, and not being able to ſee clearly where that gentleman in his opinion had erred, he did not venture to make his own ſolution public. In the courſe of that year, having procured the Memoirs of the Berlin Academy for 1757, which contain M. Euler's ſolution of the problem, he found that this gentleman's ſolution gave the ſame reſult as had been deduced by d'Alembert; but the perſpicuity of Euler's manner of writing enabled him to diſcover where he had differed from his own, which the obſcurity of the other did not do. The agreement, however, of two writers of ſuch eſtabliſhed reputation as Euler and d'Alembert made him long dubious of the truth of his own ſolution, and induced him to reviſe the proceſs again and again with the utmoſt circumſpection; and being every time more convinced that his own ſolution was right, and theirs wrong, he at length gave it to the public, in the 75th volume of the Philoſophical Tranſactions, for 1785.

The extreme difficulty of the ſubject, joined to the conciſe manner in which Mr. Landen had been obliged to give his ſolution, to confine it within proper limits for the Tranſactions, rendered it too difficult, or at leaſt too laborious a taſk for moſt mathematicians to read it; and this circumſtance, joined to the eſtabliſhed reputation of Euler and d'Alembert, induced many to think that their ſolution was right, and Mr. Landen's wrong; and there did not want attempts to prove it; particularly a long and ingenious paper by the learned Mr. Wildbore, a gentleman of very diſtinguiſhed talents and experience in ſuch calculations; this paper is given in the 80th volume of the Philoſophical Tranſactions, for the year 1790, in which he agrees with the ſolutions of Euler and d'Alembert, and againſt that of Mr. Landen. This determined the latter to reviſe and extend his ſolution, and give it at greater length, to render it more generally underſtood. About this time alſo he met by chance with the late Friſi's *Coſmographiæ Phyſicæ et Mathematicæ*; in the ſecond part of which

which there is a ſolution of this problem, agreeing in the reſult with thoſe of Euler and d'Alembert. Here Mr. Landen learned that Euler had reviſed the ſolution which he had given formerly in the Berlin Memoirs, and given it another form, and at greater length, in a volume publiſhed at Roſtoch and Gryphiſwald in 1765, intitled, *Theoria Motûs Corporum Solidorum ſeu Rigidorum.* Having therefore procured this book, Mr. Landen found the ſame principles employed in it, and of courſe the ſame concluſion reſulting from them, as in M. Euler's former ſolution of the problem. But notwithſtanding that there were thus a coincidence of at leaſt four moſt reſpectable mathematicians againſt him, Mr. Landen was ſtill perſuaded of the truth of his own ſolution, and prepared to defend it. And as he was convinced of the neceſſity of explaining his ideas on the ſubject more fully, ſo he now found it neceſſary to loſe no time in ſetting about it. He had for ſeveral years been ſeverely afflicted with the ſtone in the bladder, and towards the latter part of his life to ſuch a degree as to be confined to his bed for more than a month at a time: yet even this dreadful diſorder did not extinguiſh his ardour for mathematical ſtudies; for the ſecond volume of his *Memoirs*, lately publiſhed, was written and reviſed during the intervals of his diſorder. This volume, beſides a ſolution of the general problem concerning rotatory motion, contains the reſolution of the problem relating to the motion of a Top; with an inveſtigation of the motion of the Equinoxes, in which Mr. Landen has firſt of any one pointed out the cauſe of Sir Iſaac Newton's miſtake in his ſolution of this celebrated problem; and ſome other papers of conſiderable importance. He juſt lived to ſee this work finiſhed, and received a copy of it the day before his death, which happened on the 15th of January 1790, at Milton, near Peterborough, in the 71ſt year of his age.

LARBOARD, the left-hand ſide of a ſhip, when a perſon ſtands with his face towards the head.

LARMIER, in Architecture, a flat ſquare member of the cornice below the cimaſium, and jets out fartheſt; being ſo called from its uſe, which is to diſperſe the water, and cauſe it to fall at a diſtance from the wall, drop by drop, or, as it were, by tears; *larme* in French ſignifying a tear.

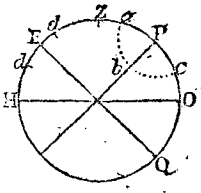
LATERAL EQUATION, in Algebra, is the ſame with ſimple equation. It has but one root, and may be conſtructed by right lines only.

LATION, is uſed by ſome, for the tranſlation or motion of a body from one place to another.

LATITUDE, in Geography, or Navigation, the diſtance of a place from the equator; or an arch of the meridian, intercepted between its zenith and the equator. Hence the Latitude is either north or ſouth, according as the place is on the north or ſouth ſide of the equator: thus London is ſaid to be in 51° 31′ of north latitude.

Circles parallel to the equator are called *parallels of latitude*, becauſe they ſhew the latitudes of places by their interſections with the meridian.

The Latitude of a place is equal to the elevation of the pole above the horizon of the place: and hence theſe two terms are uſed indifferently for each other.



This will be evident from the figure, where the circle ZHQP is the meridian, Z the zenith of the place, HO the horizon, EQ the equator, and P the pole; then is ZE the latitude, and PO the elevation of the pole above the horizon. And becauſe PE is = ZO, being each a quadrant, if the common part PZ be taken from both, there will remain the latitude ZE = PO the elevation of the pole.—Hence we have a method of meaſuring the circumference of the earth, or of determining the quantity of a degree on its ſurface; for by meaſuring directly northward or ſouthward, till the pole be one degree higher or lower, we ſhall have the number of miles in a degree of a great circle on the ſurface of the earth; and conſequently multiplying that by 360, will give the number of miles round the whole circumference of the earth.

The knowledge of the Latitude of the place, is of the utmoſt conſequence, in geography, navigation, and aſtronomy; it may be proper therefore to lay down ſome of the beſt ways of determining it, both by ſea and land.

1ſt. One method is, to find the Latitude of the pole, to which it is equal, by means of the pole ſtar, or any other circumpolar ſtar, thus: Either draw a true meridian line, or find the times when the ſtar is on the meridian, both above and below the pole; then at theſe times, with a quadrant, or other fit inſtrument, take the altitudes of the ſtar; or take the ſame when the ſtar comes upon your meridian line; which will be the greateſt and leaſt altitude of the ſtar: then ſhall half the ſum of the two be the elevation of the pole, or the latitude ſought.—For, if *abc* be the path of the ſtar about the pole P, Z the zenith, and HO the horizon: then is *a*O the altitude of the ſtar upon the meridian when above the pole, and *c*O the ſame when below the pole; hence, becauſe *a*P = *c*P, therefore *a*O + *c*O = 2OP, hence the height of the pole OP, or latitude of Z, is equal to half the ſum of *a*O and *c*O.

2d. A ſecond method is by means of the declination of the ſun, or a ſtar, and one meridian altitude of the ſame, thus: Having, with a quadrant, or other inſtrument, obſerved the zenith diſtance Z*d* of the luminary; or elſe its altitude H*d*, and taken its complement Z*d*; then to this zenith diſtance, add the declination *d*E when the luminary and place are on the ſame ſide of the equator, or ſubtract it when on different ſides, and the ſum or difference will be the latitude EZ ſought. But note, that all altitudes obſerved, muſt be corrected for refraction and the dip of the horizon, and for the ſemidiameter of the ſun, when that is the luminary obſerved.

Many other methods of obſerving and computing the Latitude may be ſeen in Robertſon's Navigation; ſee book 5 and book 9. See alſo the Nautical Almanac for 1771.

Mr. Richard Graham contrived an ingenious inſtrument for taking the latitude of a place at any time of the day. See Philoſ. Tranſ. N°. 435, or Abr. vol. 8. pa. 371.

LATITUDE, in Aſtronomy, as of a ſtar or planet, is its diſtance from the ecliptic, being an arch of a circle of latitude, reckoned from the ecliptic towards its poles, either north or ſouth. Hence, the aſtronomical latitude is quite different from the geographical, the former meaſuring from the ecliptic, and the latter from the equator, ſo that this latter anſwers to the declination in aſtronomy, which meaſures from the equinoctial.

The ſun has no latitude, being always in the ecliptic; but all the ſtars have their ſeveral latitudes, and the planets are continually changing their latitudes, ſometimes north, and ſometimes ſouth, croſſing the ecliptic from the one ſide to the other; the points in which they croſs the ecliptic being called the *nodes* of the planet, and in theſe points it is that they can paſs over the face of the ſun, or behind his body, viz, when they come both to this point of the ecliptic at the ſame time.

Circle of LATITUDE, is a great circle paſſing through the poles of the ecliptic, and conſequently perpendicular to it, like as the meridians are perpendicular to the equator, and paſs through its poles.

LATITUDE, *of the Moon, North aſcending*, is when ſhe proceeds from the aſcending node towards her northern limit, or greateſt elongation.

LATITUDE, *North deſcending*, is when the moon returns from her northern limit towards the deſcending node.

LATITUDE, *South deſcending*, is when ſhe proceeds from the deſcending node towards her ſouthern limit.

LATITUDE, *South aſcending*, is when ſhe returns from her ſouthern limit towards her aſcending node.

And the ſame is to be underſtood of the other planets.

Heliocentric LATITUDE, of a planet, is its latitude, or diſtance from the ecliptic, ſuch as it would appear from the ſun.—This, when the planet comes to the ſame point of its orbit, is always the ſame, or unchangeable.

Geocentric LATITUDE, of a planet, is its latitude as ſeen from the earth.—This, though the planet be in the ſame point of its orbit, is not always the ſame, but alters according to the poſition of the earth, in reſpect to the planet.

The latitude of a ſtar is altered only by the aberration of light, and the ſecular variation of latitude.

Difference of LATITUDE, is an arc of the meridian, or the neareſt diſtance between the parallels of latitude of two places. When the two latitudes are of the ſame name, either both north or both ſouth, ſubtract the leſs latitude from the greater, to give the difference of latitude; but when they are of different names, add them together for the difference of latitude.

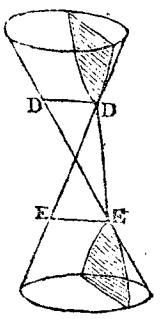
Middle LATITUDE, is the middle point between two latitudes or places; and is found by taking half the ſum of the two.

Parallax of LATITUDE. See PARALLAX.

Refraction of LATITUDE. See REFRACTION.

LATUS RECTUM, in Conic Sections, the ſame with parameter; which ſee.

LATUS *Tranſverſum*, of the hyperbola, is the right line between the vertices of the two oppoſite ſections; or that part of their common axis lying between the two oppoſite cones; as the line DE. It is the ſame as the tranſverſe axis of the hyperbola, or oppoſite hyperbolas.



LATUS *Primarium*, a right line, DD, or EE, drawn through the vertex of the ſection of a cone, within the ſame, and parallel to the baſe.

LEAGUE, an extent of three miles in length. A nautical league, or three nautical miles, is the 20th part of a degree of a great circle.

LEAP-YEAR, the ſame as BISSEXTILE; which ſee. It is ſo called from its leaping a day more that year than in a common year; conſiſting of 366 days, and a common year only of 365. This happens every 4th year, except only ſuch complete centuries as are not exactly diviſible by 4; ſuch as the 17th, 18th, 19th, 21ſt &c. centuries, becauſe 17, 18, 19, 21, &c, cannot be divided by 4 without a remainder.

To find Leap Year, &c. Divide the number of the year by 4; then if 0 remain, it is leap-year; but if 1, 2, or 3 remain, it is ſo many after leap-year.

Or the rule is ſometimes thus expreſſed, in theſe two memorial verſes:

Divide by 4; what's left ſhall be,
For leap-year 0; for paſt, 1, 2, or 3.

Thus if it be required to know what year 1790 is:

then 4) 1790 (447
2 remains:

ſo that 2 remaining, ſhews that 1790 is the 2d year after leap-year. And to find what year 1796 is:

then 4) 1796 (449

here 0 remaining, ſhews that 1796 is a leap-year.

LEAVER. See LEVER.

LEE, a term in Navigation, ſignifying that ſide, or quarter, towards which the wind blows.

LEE-WAY, of a Ship, is the angle made by the point of the compaſs ſteered upon, and the real line of the ſhip's way, occaſioned by contrary winds and a rough ſea.

All ſhips are apt to make ſome lee-way; ſo that ſomething muſt be allowed for it, in caſting up the log-board. But the lee-way made by different ſhips, under ſimilar circumſtances of wind and ſails, is different; and even the ſame ſhip, with different lading, and having more or leſs ſail ſet, will have more or leſs lee-way. The uſual allowances for it are theſe, as they were given by Mr. John Buckler to the late ingenious Mr. William Jones, who firſt publiſhed them in 1702 in his *Compendium of Practical Navigation*. 1ſt, When a ſhip is cloſe-hauled, has all her ſails ſet, the ſea ſmooth, and a moderate gale of wind, it is then ſuppoſed ſhe makes little or no lee-way. 2d, Allow one point, when it blows ſo freſh that the ſmall ſails are taken in. 3d, Allow two points, when the topſail muſt be cloſe reefed. 4th, Allow two points and a half, when one topſail muſt be handed. 5th, Allow three points and a half, when both topſails muſt be taken in. 6th, Allow four points, when the fore-courſe is handed. 7th, Allow five points, when trying under the mainſail only. 8th, Allow ſix points, when both main and fore-courſes are taken in.

9th,

9th, Allow ſeven points, when the ſhip tries a-hull, or with all ſails handed.

When the wind has blown hard in either quarter, and ſhifts acroſs the meridian into the next quarter, the lee-way will be leſſened. But in all theſe caſes, reſpect muſt be had to the roughneſs of the ſea, and the trim of the ſhip. And hence the mariner will be able to correct his courſe.

LEGS, *of a Triangle.* When one ſide of a triangle is taken as the baſe, the other two are ſometimes called the legs. The term is often uſed too for the baſe and perpendicular of a right-angled triangle, or the two ſides about the right angle.

Hyperbolic LEGS, are the ends of a curve line that partake of the nature of the hyperbola, or having aſymptotes.

LEIBNITZ (GODFREY-WILLIAM), an eminent mathematician and philoſopher, was born at Leipſic in Saxony in 1646. At the age of 15, he applied himſelf to mathematics at Leipſic and Jena; and in 1663, maintained a theſis *de Principiis Individuationis.* The year following he was admitted Maſter of Arts. He read with great attention the Greek philoſophers; and endeavoured to reconcile Plato with Ariſtotle, as he afterwards did Ariſtotle with Des Cartes. But the ſtudy of the law was his principal view; in which faculty he was admitted Bachelor in 1665. The year following he would have taken the degree of Doctor; but was refuſed it on pretence that he was too young, though in reality becauſe he had raiſed himſelf ſeveral enemies by rejecting the principles of Ariſtotle and the Schoolmen.

Upon this he repaired to Altorf, where he maintained a theſis *de Caſibus Perplexis,* with ſuch applauſe, that he had the degree of Doctor conferred on him.

In 1672 he went to Paris, to manage ſome affairs at the French Court for the baron Boinebourg. Here he became acquainted with all the Literati, and made farther and conſiderable progreſs in the ſtudy of mathematics and philoſophy, chiefly, as he ſays, by the works of Paſcal, Gregory St. Vincent, and Huygens. In this courſe, having obſerved the imperfection of Paſcal's arithmetical machine, he invented a new one, as he called it, which was approved of by the miniſter Colbert, and the Academy of Sciences, in which he was offered a ſeat as a member, but refuſed the offers made to him, as it would have been neceſſary to embrace the Catholic religion.

In 1673, he came over to England; where he became acquainted with Mr. Oldenburg, ſecretary of the Royal Society, and Mr. John Collins, a diſtinguiſhed member of the Society; from whom it ſeems he received ſome hints of the method of fluxions, which had been invented, in 1664 or 1665, by the then Mr. Iſaac Newton.

The ſame year he returned to France, where he reſided till 1676, when he again paſſed through England, and Holland, in his journey to Hanover, where he propoſed to ſettle. Upon his arrival there, he applied himſelf to enrich the duke's library with the beſt books of all kinds. The duke dying in 1679, his ſucceſſor Erneſt Auguſtus, then biſhop of Oſnaburgh, ſhewed Mr. Leibnitz the ſame favour as his predeceſſor had done, and engaged him to write the Hiſtory of the Houſe of Brunſwick. To execute this taſk, he travelled over Germany and Italy, to collect materials. While he was in Italy, he met with a pleaſant adventure, which might have proved a more ſerious affair. Paſſing in a ſmall bark from Venice to Meſola, a ſtorm aroſe; during which the pilot, imagining he was not underſtood by a German, whom, being a heretic, he looked on as the cauſe of the tempeſt, propoſed to ſtrip him of his cloaths and money, and throw him overboard. Leibnitz hearing this, without diſcovering the leaſt emotion, drew a ſet of beads from his pocket, and began turning them over with great ſeeming devotion. The artifice ſucceeded; one of the ſailors obſerving to the pilot, that, ſince the man was no heretic, he ought not to be drowned.

In 1700 he was admitted a member of the Royal Academy of Sciences at Paris. The ſame year the elector of Brandenburg, afterwards king of Pruſſia, founded an academy at Berlin by his advice; and he was appointed perpetual Preſident, though his affairs would not permit him to reſide conſtantly at that place. He projected an academy of the ſame kind at Dreſden; and this deſign would have been executed, if it had not been prevented by the confuſions in Poland. He was engaged likewiſe in a ſcheme for an univerſal language, and other literary projects. Indeed his writings had made him long before famous over all Europe, and he had many honours and rewards conferred on him. Beſide the office of Privy Counſellor of Juſtice, which the elector of Hanover had given him, the emperor appointed him, in 1711, Aulic Counſellor; and the czar made him Privy Counſellor of Juſtice, with a penſion of 1000 ducats. Leibnitz undertook at the ſame time to eſtabliſh an academy of ſciences at Vienna; but the plague prevented the execution of it. However, the emperor, as a mark of his favour, ſettled a penſion on him of 2000 florins, and promiſed him one of 4000 if he would come and reſide at Vienna; an offer he was inclined to comply with, but was prevented by his death.

Meanwhile, the Hiſtory of Brunſwick being interrupted by other works which he wrote occaſionally, he found, at his return to Hanover in 1714, that the elector had appointed Mr. Eccard for his colleague in writing that hiſtory. The elector was then raiſed to the throne of Great Britain, which place Leibnitz viſited the latter end of that year, when he received particular marks of friendſhip from the king, and was frequently at court. He now was engaged in a diſpute with Dr. Samuel Clarke, upon the ſubjects of free-will, the reality of ſpace, and other philoſophical ſubjects. This was conducted with great candour and learning; and the papers, which were publiſhed by Clarke, will ever be eſteemed by men of genius and learning. The controverſy ended only with the death of Leibnitz, Nov. 14, 1716, which was occaſioned by the gout and ſtone, in the 70th year of his age.

As to his character and perſon: He was of a middle ſtature, and a thin habit of body. He had a ſtudious air, and a ſweet aſpect, though near-ſighted. He was indefatigably induſtrious to the end of his life. He eat and drank little. Hunger alone marked the time of his meals, and his diet was plain and ſtrong.

He had a very good memory, and it was ſaid could repeat the Æneid from beginning to end. What he wanted to remember, he wrote down, and never read it afterwards. He always profeſſed the Lutheran religion, but never went to ſermons; and when in his laſt ſickneſs his favourite ſervant deſired to ſend for a miniſter, he would not permit it, ſaying he had no occaſion for one. He was never married, nor ever attempted it but once, when he was about 50 years old; and the lady deſiring time to conſider of it, gave him an opportunity of doing the ſame: he uſed to ſay, "that marriage was a good thing, but a wiſe man ought to conſider of it all his life."

Leibnitz was author of a great multitude of writings; ſeveral of which were publiſhed ſeparately, and many others in the memoirs of different academies. He invented a binary arithmetic, and many other ingenious matters. His claim to the invention of Fluxions, has been ſpoken of under that article. Hanſchius collected, with great care, every thing that Leibnitz had ſaid, in different paſſages of his works, upon the principles of philoſophy; and formed of them a complete ſyſtem, under the title of *G. G. Leibnitzii Principia Philoſophiæ more geometrico demonſtrata* &c, 1728, in 4to. There came out a collection of our author's letters in 1734 and 1735, intitled, *Epiſtolæ ad diverſos theologici, juridici, medici, philoſophici, mathematici, hiſtorici, & philologici argumenti e MSS. auctores: cum annotationibus ſuis primum divulgavit Chriſtian Cortholtus.* But all his works were collected, diſtributed into claſſes by M. Dutens, and publiſhed at Geneva in ſix large volumes 4to, in 1768, intitled, *Gothofredi Guillelmi Leibnitii Opera Omnia &c.*

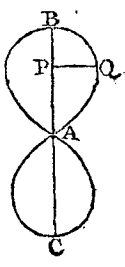
Leibnitzian Philosophy, or the Philoſophy of Leibnitz, is a ſyſtem formed and publiſhed by its author in the laſt century, partly in emendation of the Carteſian, and partly in oppoſition to the Newtonian philoſophy. In this philoſophy, the author retained the Carteſian ſubtile matter, with the vortices and univerſal plenum; and he repreſented the univerſe as a machine that ſhould proceed for ever, by the laws of mechaniſm, in the moſt perfect ſtate, by an abſolute inviolable neceſſity. After Newton's philoſophy was publiſhed, in 1687, Leibnitz printed an Eſſay on the celeſtial motions in the Act. Erud. 1689, where he admits the circulation of the ether with Des Cartes, and of gravity with Newton; though he has not reconciled theſe principles, nor ſhewn how gravity aroſe from the impulſe of this ether, nor how to account for the planetary revolutions in their reſpective orbits. His ſyſtem is alſo defective, as it does not reconcile the circulation of the ether with the free motions of the comets in all directions, or with the obliquity of the planes of the planetary orbits; nor reſolve other objections to which the hypotheſis of the vortices and plenum is liable.

Soon after the period juſt mentioned, the diſpute commenced concerning the invention of the method of Fluxions, which led Mr. Leibnitz to take a very decided part in oppoſition to the philoſophy of Newton. From the goodneſs and wiſdom of the Deity, and his principle of a *ſufficient reaſon*, he concluded, that the univerſe was a perfect work, or the beſt that could poſſibly have been made; and that other things, which are evil or incommodious, were permitted as neceſſary conſequences of what was beſt: that the material ſyſtem, conſidered as a perfect machine, can never fall into diſorder, or require to be ſet right; and to ſuppoſe that God interpoſes in it, is to leſſen the ſkill of the author, and the perfection of his work. He expreſsly charges an impious tendency on the philoſophy of Newton, becauſe he aſſerts, that the fabric of the univerſe and courſe of nature could not continue for ever in its preſent ſtate, but in proceſs of time would require to be re-eſtabliſhed or renewed by the hand of its firſt framer. The perfection of the univerſe, in conſequence of which it is capable of continuing for ever by mechanical laws in its preſent ſtate, led Mr. Leibnitz to diſtinguiſh between the quantity of motion and the force of bodies; and, whilſt he owns in oppoſition to Des Cartes that the former varies, to maintain that the quantity of force is for ever the ſame in the univerſe; and to meaſure the forces of bodies by the ſquares of their velocities.

Mr. Leibnitz propoſes two principles as the foundation of all our knowledge; the firſt, that it is impoſſible for a thing to be, and not to be at the ſame time, which he ſays is the foundation of ſpeculative truth; and ſecondly, that nothing is without a *ſufficient reaſon* why it ſhould be ſo, rather than otherwiſe; and by this principle he ſays we make a tranſition from abſtracted truths to natural philoſophy. Hence he concludes that the mind is naturally determined, in its volitions and elections, by the greateſt apparent good, and that it is impoſſible to make a choice between things perfectly like, which he calls *indiſcernibles*; from whence he infers, that two things perfectly like could not have been produced even by the Deity himſelf: and one reaſon why he rejects a vacuum, is becauſe the parts of it muſt be ſuppoſed perfectly like to each other. For the ſame reaſon too, he rejects atoms, and all ſimilar parts of matter, to each of which, though diviſible *ad infinitum*, he aſcribes a *monad* (Act. Lipſiæ 1698, pa. 435) or active kind of principle, endued with perception and appetite. The eſſence of ſubſtance he places in action or activity, or, as he expreſſes it, in ſomething that is between acting and the faculty of acting. He affirms that abſolute reſt is impoſſible, and holds that motion, or a ſort of *niſus*, is eſſential to all material ſubſtances. Each monad he deſcribes as repreſentative of the whole univerſe from its point of ſight; and yet he tells us, in one of his letters, that matter is not a ſubſtance, but a *ſubſtantiatum*, or *phenomené bien fondé*. See alſo Maclaurin's View of Newton's Philoſophical Diſcoveries, book 1, chap. 4.

LEMMA, is a term chiefly uſed by mathematicians, and ſignifies a propoſition, previouſly laid down to prepare the way for the more eaſy apprehenſion of the demonſtration of ſome theorem, or the conſtruction of ſome problem.

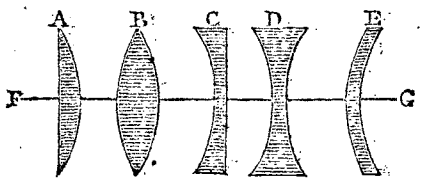
LEMNISCATE, the name of a curve in the form of the figure of 8. If we call AP, x; PQ, y, and the conſtant line AB or AC, a; the equation $ay = x\sqrt{aa - xx}$, or $a^2y^2 = a^2x^2 - x^4$, expreſſing a line of the 4th degree, will denote a lemniſcate, having a double point in the point A. There may be other lemniſcates, as the ellipſe of Caſſini, &c; but that above defined is the ſimpleſt of them.



It eaſily appears that this curve is quadrable. For ſince $ay = x\sqrt{a^2-x^2}$, therefore the fluxion of the curve or $y\dot{x}$ is $= \frac{x}{a}\dot{x}\sqrt{a^2-x^2}$; the fluent of which is $\frac{1}{3}a^2 - \frac{1}{3a}\overline{a^2-x^2}^{\frac{3}{2}}$ for the general area of the curve; which, when x is $= a$, becomes barely $\frac{1}{3}a^2 =$ AQB.

LENS, a piece of glaſs or other tranſparent ſubſtance, having its two ſurfaces ſo formed that the rays of light, in paſſing through it, have their direction changed, and made to converge and tend to a point beyond the lens, or to become parallel after converging or diverging, or laſtly to diverge as if they had proceeded from a point before the lens. Some lenſes are convex, or thicker in the middle; others concave, or thinner in the middle; while others are plano-convex, or plano-concave; and ſome again are convex on one ſide and concave on the other, which are called meniſcuſes, the properties of which ſee under that word. When the particular figure is not conſidered, a lens that is thickeſt in the middle is called a convex lens; and that which is thinneſt in the middle is called a concave lens, without farther diſtinction.

Theſe ſeveral forms of lenſes are repreſented in the annexed figure:



where A, B are convex lenſes, and C, D, E are concave ones; alſo A is a plano-convex, B is convexo-convex, C is plano-concave, D is concavo-concave, and E is a meniſcus.

In every lens, the right line perpendicular to the two ſurfaces, is called the Axis of the lens, as F G; the points where the axis cuts the ſurface, are called the Vertices of the lens; alſo the middle point between them is called the Centre; and the diſtance between them, the Diameter.

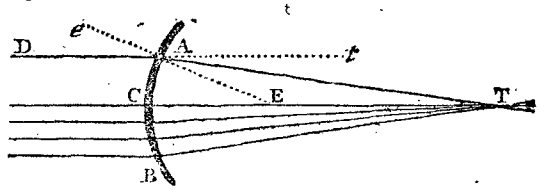
Some confine lenſes within the diameter of half an inch; and ſuch as exceed that thickneſs, they call Lenticular Glaſſes.

Lenſes are either blown or ground.

Blown LENSES, are ſmall globules of glaſs, melted in the flame of a lamp or taper. See Microſcope.

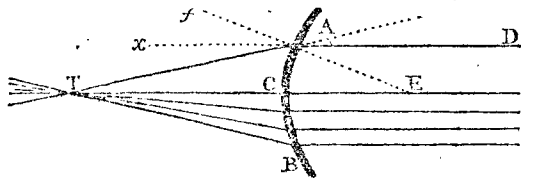
Ground LENSES, are ſuch as are ground or rubbed into the deſired ſhape, and then poliſhed. For a method of grinding them, and deſcription of a machine for that purpoſe, ſee Philoſ. Tranſ. vol. xli. pa. 555, or Abr. viii. 281.

Maurolycus firſt delivered ſomething relative to the nature of lenſes; but we are chiefly indebted to Kepler for explaining the doctrine of refraction through mediums of different forms, the chief ſubſtance of which may be comprehended in the caſes following.

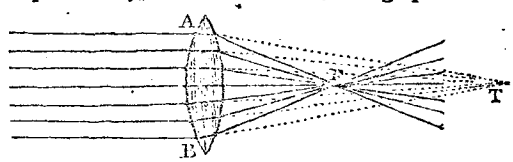


Let DA be a ray of light falling upon a convex denſe medium, having its centre at E. When the ray arrives at A, it will not proceed in the ſame direction A*t*, but it will be there bent, and thrown into a direction AT, nearer the perpendicular AE. In the ſame manner, another ray falling on B, at an equal diſtance on the other ſide of the vertex C, and parallel to the former ray DA, will be refracted into the ſame point T. And it will alſo be found, that all the intermediate parallel rays will converge to the ſame point, very nearly.

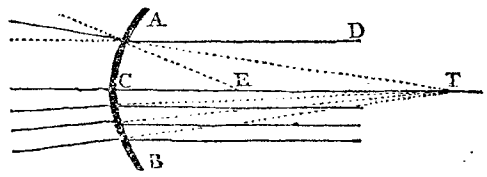
On the other hand, if the rays fall parallel on the inſide of this denſer medium, as in the fig. below, they will tend from the perpendicular EA*f*; and converge to a point T in the air, or any rarer medium. Alſo the ray incident on B, at the ſame diſtance from the vertex C, will converge to the ſame place T, together with all the intermediate parallel rays.



Since therefore rays are made to converge when they paſs either from a rarer or a denſer medium terminated by a convex ſurface, and converge again when they paſs from the ſame medium convex towards the rarer, a lens which is convex on both ſides muſt, on both accounts, make parallel rays converge to a point beyond it. Thus, the parallel rays between A and B, falling upon

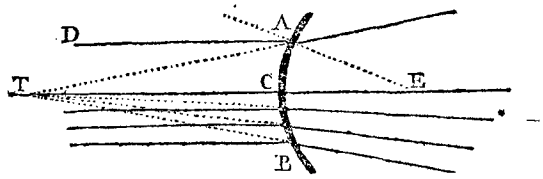


the convex ſurface of the glaſs AB, would in that denſe medium have converged to T; but that medium being terminated by another convex ſurface, they will be made more converging, and be collected at ſome place F, nearer to the lens.

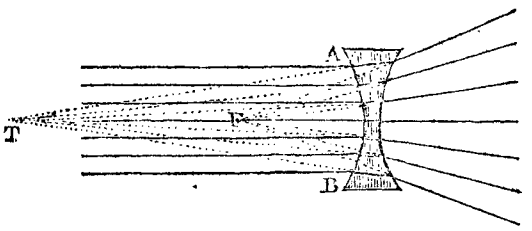


Again, to explain the effects of a concave glaſs, let AB be the concave ſide of a denſe medium, the centre of concavity being at E. In this caſe, DA will be refracted

fracted towards the perpendicular EA; and ſo likewiſe will the ray incident at B; in conſequence of which they will diverge from one another within the denſe medium. The intermediate rays will alſo diverge more or leſs, as they recede from the axis TC; which, being in the perpendicular, will go ſtraight on.



If the rays be parallel within the denſe medium, they will diverge when they paſs from thence into a rarer medium, through a concave ſurface. For the ray DA will be refracted from the perpendicular AE, as will alſo the ray that is incident at B, together with all the intermediate rays, in proportion to their diſtance from the axis or central ray TC.



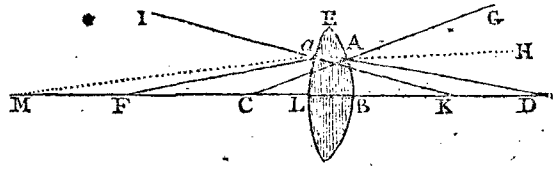
Therefore, if a denſe medium, as the glaſs AB, be terminated by two concave ſurfaces, parallel rays paſſing through it will be made to diverge by both the ſides of it. Thus the firſt ſurface AB will make them diverge as if they had come from the point T; and with the effect of the ſecond ſurface added to this, they will diverge as from a nearer point, F.

It was Kepler, who by theſe inveſtigations firſt gave a clear explanation of the effects of lenſes, in making the rays of a pencil of light converge or diverge. He ſhewed that a plano-convex lens makes rays, that were parallel to its axis, meet at the diſtance of the diameter of the ſphere of convexity; but that if both ſides of the lens be equally convex, the rays will have their focus at the diſtance of the radius of the circle corresponding to that degree of convexity. But he did not inveſtigate any rule for the foci of lenſes unequally convex. He only ſays, in general, that they will fall ſomewhere in the medium, between the foci belonging to the two different degrees of convexity. It is to Cavalerius that we owe this inveſtigation: he laid down this rule, As the ſum of both the diameters is to one of them, ſo is the other to the diſtance of the focus. And it is to be noted that all theſe rules, concerning convex lenſes, are applicable to thoſe that are concave, with this difference, that the focus is on the contrary ſide of the glaſs. See Montucla, vol. 2, pa. 176; or Prieſtley's Hiſt. of Viſion, pa. 65, 4to.

Upon this principle it was not difficult to find the foci of pencils of rays iſſuing from any point in the axis of the lens; ſince thoſe that are parallel will meet in the focus; and if they iſſue from the focus, they will be parallel on the other ſide. If they iſſue from a point between the focus and the glaſs, they will continue to diverge after paſſing the lens, but leſs than before; while thoſe that come from beyond the focus, will converge after paſſing the glaſs, and will meet in a place beyond the oppoſite focus. This philoſopher particularly obſerved, that rays which iſſue from twice the diſtance of the focus, will meet at the ſame diſtance on the other ſide. The moſt important of theſe obſervations have been already illuſtrated by proper figures, and from them the reſt may be eaſily conceived. Later optical writers have aſſigned the diſtances at which rays will meet, that iſſue from any other place in the axis of a lens; but Kepler was too much intent upon his aſtronomical and other purſuits, to give much attention to geometry. But, from the whole, Montucla gives the following rule concerning this ſubject: As the exceſs of the diſtance of the object from the glaſs, above the diſtance of the focus, is to the diſtance of the focus; ſo is this diſtance, to the place of convergency beyond the glaſs. And the ſame rule will find the point of divergency, when the rays iſſue from any place between the lens and the focus: for then the exceſs of the diſtance of the object from the glaſs, above that of the focus, is negative, which is the ſame diſtance taken the contrary way. Montucla, vol. 2, pa. 177.

And from the principle above-mentioned, it will not be difficult to underſtand the application of lenſes, in the rationale of teleſcopes and microſcopes. On theſe principles too is founded the ſtructure of refracting burning glaſſes, by which the ſun's light and heat are exceedingly augmented in the focus of the lens, whether convex or plano-convex; ſince the rays, falling parallel to the axis of the lens, are reduced into a much narrower compaſs; ſo that it is no wonder they burn ſome bodies, melt others, and produce other extraordinary phenomena.

In the Philoſ. Tranſ. vol. xvii. 960, or the Abr. i. 191, Dr. Halley gives an ingenious inveſtigation of the foci of rays refracted through any lenſes, nearly as follows:



Let BEL be a double convex lens, C the centre of the ſegment EB, and K the centre of the ſegment EL; BL the thickneſs or diameter of the lens, and D a point in the axis; it is required to find the point F, or focus, where the rays proceeding from D ſhall be collected, after being refracted through the lens at A and *a*, points very near to the axis BL. Put the diſtance DA or DB=*d*, the radius CA or CB=*r*, and the radius K*a* or KL=R; alſo the thickneſs of the lens BL=*t*, and *m* to *n* the ratio of the ſine of the angle of incidence DAG to the ſine of the refracted angle HAG or CAM; or *m* to *n* will be the ratio of thoſe angles themſelves nearly, ſince very ſmall angles are to each other in the ſame ratio as their ſines. Hence

m is as the angle DAG or DAC,
n is as the angle HAG or MAC,

and becauſe in this caſe the ſides are as their oppo-

site angles, therefore DC : DA :: ∠DAC : ∠C,
or $d+r : d :: m : \frac{dm}{d+r}$ which is as the ∠C;
from this take n or the ∠ MAC,
and there remains $\frac{dm-dn-rn}{d+r}$ as the ∠M;
hence again ∠M : ∠C :: CA : MA or MB,
that is $\frac{dm-dn-rn}{d+r} : \frac{dm}{d+r} :: r : \frac{mdr}{m-n \cdot d-nr} =$ MA
or MB; which shews in what point the rays would be collected after one refraction, viz, when nr is less than $m-n \cdot d$. But when nr is $= m-n \cdot d$, the point would be at an infinite distance, or the rays will be parallel to the axis; and when nr is greater than $m-n \cdot d$, then MB is negative, or M falls on the other side of the lens beyond D, and the rays still continue to diverge after the first refraction.

The point M being now found, to or from which the rays proceed after the first refraction, and BM − BL being thus given, which call D, by a process like the former it follows that FL, or the focal distance sought, is equal to $\frac{nDR}{m-n \cdot D+nR} = f$. And here, instead of D substituting MB − LB or $\frac{mdr}{m-n \cdot d-nr} - t$, and putting p for $\frac{n}{m-n}$, the same theorem will become

$$\frac{(mpdr - ndt + nprt) \times R}{mdr + md R - mprR - m-n \cdot dt + nrt} = f,$$

the focal distance sought, in its most general form, including the thickness of the lens; being the universal rule for the foci of double convex glasses exposed to diverging rays.

But if t the thickness of the lens be rejected, as not sensible, the rule will be much shorter, viz, $\frac{pdrR}{dr + dR - prR} = f$.

If therefore the lens consist of glass, whose refraction is as 3 to 2, it will be $\frac{2drR}{dr + dR - 2rR} = f$. And if it be of water, whose refraction is as 4 to 3, it will be $\frac{3drR}{dr + dR - 3rR} = f$. But, if the lens could be made of diamond, whose refraction is as 5 to 2, it would be $\frac{2drR}{3dr + 3dR - 2rR} = f$.

If the incident rays, instead of diverging, be converging, the distance DB or d will be negative, and then the theorem for a double convex glass lens will be $\frac{-2drR}{-dr - dR - 2rR}$ or $\frac{2drR}{dr + dR + 2rR} = f$, in which case therefore the focus is always on the other side of the glass.

And if the rays be parallel, as coming from an infinite distance, or nearly so, then will d be negative, as well as the terms in the theorem in which it is found; and therefore, the other term prR will be nothing in respect of those infinite terms; and by omitting it, the theorem will be $\frac{pdrR}{dr+dR} = \frac{prR}{r+R} = f$,
or for glass $\frac{2rR}{r+R} = f$.

And here if $r = R$, or the two sides of the glass be of equal convexity, this last will become barely $\frac{2r^2}{2r}$ or barely $r = f$ the focus, which therefore is in the centre of the convexity of the lens.

If the lens be a meniscus of glass; then, making r negative, the theorem is

$\frac{-2drR}{-dr + dR + 2rR}$ or $\frac{2drR}{dr - dR - 2rR} = f$,
for diverging rays,

$\frac{-2drR}{-dr + dR - 2rR}$ or $\frac{2drR}{dr - dR + 2rR} = f$,
for converging rays,

and $\frac{-2rR}{-r+R}$ or $\frac{2rR}{r-R} = f$ for parallel rays.

If the lens be a double concave glass, r and R will be both negative, and then the theorem becomes

$\frac{-2drR}{dr + dR + 2rR} = f$ for diverging rays, always negative;

$\frac{-2drR}{dr + dR \times 2rR} = f$ for converging rays;

and $\frac{-2rR}{r+R} = f$ for parallel rays.

And here, if the radii of curvature r and R be equal, this last will be barely $-r = f$ for parallel rays falling on a double concave glass of equal curvature.

Lastly, when the lens is a plano-convex glass; then, r being infinite, the theorem becomes

$\frac{2dR}{d-2R} = f$ for diverging rays,

$\frac{2dR}{d+2R} = f$ for converging rays,

and $2R = f$ for parallel rays.

The theorems for parallel rays, as coming from an infinite distance, take place in the common refracting telescopes. And those for converging rays are chiefly of use to determine the focus resulting from any sort of lens placed in a telescope, between the focus of the object-glass and the glass itself; the distance between the said focus of the object-glass and the interposed lens being made $= -d$; while those for diverging rays are chiefly of use in microscopes, reading glasses, and other cases in which near objects are viewed.

It is evident that the foregoing general theorem will serve to find any of the other circumstances, as well as the focus, by considering this as given. Thus, for instance, suppose it be required to find the distance at which an object being placed, it shall by a given lens be represented as large as the object itself; which is of singular use in viewing and drawing them, by transmitting the image through a glass in a dark room, as in the camera obscura, which gives not only the true figure and shades, but the colours themselves as vivid as the life. Now in this case d is $= f$, which makes the theorem become $pdrR = d^2r + d^2R - pdrR$, and this

this gives $d = \frac{2prR}{r+R}$. But if the two convexities belong to equal ſpheres; ſo as that $r = R$, then it is $d = pr$, or $= 2r$ when the lens is glaſs. So that if the object be placed at the diameter of the ſphere diſtant from the lens, then the focus will be as far diſtant on the other ſide, and the image as large as the object. But if the glaſs were a plano-convex, the ſame diſtance would be juſt twice as much.

Again, recurring to the firſt general theorem, including t, the thickneſs of the lens; let the lens be a whole ſphere; then $t = 2r$, and $r = R$; and hence the theorem reduces to $\frac{mpdr - 2ndr - 2npr^2}{2nd + 2nr - mpr} = f$.

And here if d be infinite, the theorem contracts to $\frac{mp-2n}{2n}r$ or $\frac{2n-m}{2m-2n}r = f$; or for glaſs $\frac{1}{2}r = f$: ſhewing that a ſphere of glaſs collects the ſun's rays at half the radius of the ſphere without it. And for a ſphere of water, the focus is at the diſtance of a whole radius.

For another example; when a hemiſphere is expoſed to parallel rays; then d and R being infinite, and $t = r$, the theorem becomes $\frac{mp-n}{m}r$, $= \frac{nn}{m^2-mn}r = f$. That is, in glaſs it is $\frac{2}{3}r$, and in water $\frac{3}{4}r$.

Several other corollaries may be deduced from the foregoing principles. As,

1ſt. That the thickneſs of the lens, being very ſmall, the focus will remain the ſame, whether the one ſide or the other be expoſed to the rays.

2d. If a luminous body be placed in a focus behind a lens, whether plano-convex, or convex on both ſides; or whether equally or unequally ſo; the rays become parallel after refraction, as the refracted rays become what were before the incident rays. And hence, by means of a convex lens, or a little glaſs bubble full of water, a very intenſe light may be projected to a great diſtance. Which furniſhes us with the ſtructure of a lamp or lantern, to throw an intenſe light to an immenſe diſtance: for a lens, convex on both ſides, being placed oppoſite to a concave mirror, if there be placed a lighted candle or wick in the common focus of both, the rays reflected back from the mirror to the lens will be parallel to each other; and after refraction will converge, till they concur at the diſtance of the radius, after which they will again diverge. But the candle being likewiſe in the focus of the lens, the rays it throws on the lens will be parallel; and therefore a very intenſe light meeting with another equally intenſe, at the diſtance of the diameter from the lens, the light will be ſurpriſing: and though it afterwards decreaſe, yet the parallel and diverging rays going a long way together, it will be very great at a great diſtance. Lanterns of this kind are of conſiderable ſervice in the night time, to diſcover remote objects; and are uſed with ſucceſs by fowlers and fiſhermen, to collect their prey together, that ſo it may be taken.

If it be required to have the light, at the ſame time, tranſmitted to ſeveral places, as through ſeveral ſtreets, &c, the number of lenſes and mirrors muſt be increaſed.

3d. The images of objects are ſhewn inverted in the focus of a convex lens: nor is the focus of the ſun's rays any thing elſe, in effect, but the image of the ſun inverted. Hence, in ſolar eclipſes, the ſun's image, eclipſed as it is, may be burnt by a large lens on a board, &c, and exhibit a very entertaining phenomenon.

4th. If a concave mirror be ſo placed, as that an inverted image, formed by refraction through a lens, be found between the centre and the focus, or even beyond the centre, it will again be inverted by reflection, and ſo appear erect; in the firſt caſe beyond the centre, and in the latter between the centre and the focus. And on theſe principles the camera obſcura is conſtructed.

5th. The image of an object, delineated beyond a convex lens, is of ſuch a magnitude, as it would be of, were the object to ſhine into a dark room through a ſmall hole, upon a wall, at the ſame diſtance from the hole, as the focus is from the lens.—When an object is leſs diſtant from a lens than the focus of parallel rays, the diſtance of the image is greater than that of the object; otherwiſe, the diſtance of the image is leſs than that of the object: in the former caſe, therefore, the image is larger than the object; in the latter, it is leſs.

When the images are leſs than the objects, they will appear more diſtinct and vivid; becauſe then more rays are accumulated into a given ſpace. But if the images be made greater than the objects, they will not appear diſtinctly; becauſe in that caſe there are fewer rays which meet after refraction in the ſame point; whence it happens, that rays proceeding from different points of an object, terminate in the ſame point of an image, which is the cauſe of confuſion. Hence it appears, that the ſame aperture of a lens may be admitted in every caſe, if we would keep off the rays which produce confuſion. However, though the image be then more diſtinct, when no rays are admitted but thoſe near the axis, yet for want of rays the image is apt to be dim.

6th. If the eye be placed in the focus of a convex lens, an object viewed through it, appears erect, and enlarged in the ratio of the diſtance of the object from the eye, to that of the eye from the lens, if it be near; but infinitely if remote.

7th. An object viewed through a concave lens, appears erect, and diminiſhed in a ratio compounded of the ratios of the ſpace in the axis between the point of incidence, and the point to which an oblique ray would paſs without refraction, to the ſpace in the axis between the eye and the middle of the object; and the ſpace in the ſame axis between the eye and the point of incidence, to the ſpace between the middle of the object and the point to which the oblique ray would paſs without refraction.

Finally, it may be obſerved, that the very ſmall magnifying glaſſes uſed in microſcopes, moſt properly come under the denomination of lens, as they moſt approach to the figure of the lentil, a ſeed of the vetch or pea kind, from whence the name is derived; but the reading glaſſes, and burning glaſſes, and all that magnify, come under the ſame denomination; for their ſurfaces are convex, although leſs ſo. A drop of water is a lens, and it will ſerve as one; and many have uſed it by way of

lens

lens in their microſcopes. A drop of any tranſparent fluid, incloſed between two concave glaſſes, acquires the ſhape of a lens, and has all its properties. The cryſtalline humour of the eye is a lens exactly of this kind; it is a ſmall quantity of a tranſlucent fluid, contained between two concave and tranſparent membranes, called the coats of the eye; and it acts as the lens made of water would do, in an equal degree of convexity.

LEO, *the Lion*, a conſiderable conſtellation of the northern hemiſphere, being one of the 48 old conſtellations, and the 5th ſign of the zodiac. It is marked thus ♌, as a rude ſketch of the animal.

The Greeks fabled that this was the Nemæan lion, which had dropped from the moon, but being ſlain by Hercules, was raiſed to the heavens by Jupiter, in commemoration of the dreadful conflict, and in honour of that hero. But the hieroglyphical meaning of this ſign, ſo depicted by the Egyptians long before the invention of the fables of Hercules, was probably no more than to ſignify, by the fury of the lion, the violent heats occaſioned by the ſun when he entered that part of the ecliptic.

The ſtars in the conſtellation Leo, in Ptolomy's catalogue are 27, beſides 8 unformed ones, now counted in later times in the conſtellation Coma Berenices, in Tycho's 30, in that of Hevelius 49, and in Flamſteed's 95; one of them, of the firſt magnitude, in the breaſt of the Lion, is called Regulus, and Cor Leonis, or Lion's Heart.

LEO *Minor*, *the Little Lion*, a conſtellation of the northern hemiſphere, and one of the new ones that were formed out of what were left by the ancients, under the name of Stellæ Informes, or unformed ſtars, and added to the 48 old ones. It contains 53 ſtars in Flamſteed's catalogue.

Cor LEONIS, *Lion's heart*, a fixed ſtar, of the firſt magnitude, in the ſign Leo; called alſo Regulus, Baſilicus, &c.

LEPUS, *the Hare*, a conſtellation of the ſouthern hemiſphere, and one of the 48 old conſtellations.

The Greeks fabled, that this animal was placed in the heavens, near Orion, as being one of the animals which he hunted. But it is probable their maſters, the Egyptians, had ſome other meaning in this hieroglyphic.

The ſtars in the conſtellation Lepus, in Ptolomy's catalogue are 12, in Tycho's 13, and in Flamſteed's 19.

LEUCIPPUS, a celebrated Greek philoſopher and mathematician, who flouriſhed about the 428th year before Chriſt. He was the firſt author of the famous ſyſtem of atoms and vacuums, and of the hypotheſis of ſtorms; ſince attributed to the moderns.

LEVEL, an inſtrument uſed to make a line parallel to the horizon, and to continue it out at pleaſure; and by this means to find the true level, or the difference of aſcent or deſcent between two or more places, for conveying water, draining fens, &c.

There are ſeveral inſtruments, of different contrivance and matter, invented for the perfection of levelling, as may be ſeen in De la Hire's and Picard's treatiſes of Levelling, in Biron's treatiſe on Mathematical Inſtruments, alſo in the Philoſ. Tranſ. and the Memoirs de l'Acad. &c. But they may be reduced to the following kinds.

Water-LEVEL, that which ſhews the horizontal line by means of a ſurface of water or other fluid; founded on this principle, that water always places itſelf level or horizontal.

The moſt ſimple kind is made of a long wooden trough or canal; which being equally filled with water, its ſurface ſhews the line of level. And this is the chorobates of the ancients, deſcribed by Vitruvius, lib. viii. cap. 6.

The water-level is alſo made with two cups fitted to the two ends of a ſtraight pipe, about an inch diameter, and 3 or 4 feet long, by means of which the water communicates from the one cup to the other; and this pipe being moveable on its ſtand by means of a ball and ſocket, when the two cups ſhew equally full of water, their two ſurfaces mark the line of level.

This inſtrument, inſtead of cups, may alſo be made with two ſhort cylinders of glaſs three or four inches long, faſtened to each extremity of the pipe with wax or maſtic. The pipe is filled with common or coloured water, which ſhews itſelf through the cylinders, by means of which the line of Level is determined; the height of the water, with reſpect to the centre of the earth, being always the ſame in both cylinders. This level, though very ſimple, is yet very commodious for levelling ſmall diſtances. See the method of preparing and uſing a water-level, and a mercurial Level, annexed to Davis's quadrant, for the ſame purpoſe, by Mr. Leigh, in Philoſ. Tranſ. vol. XL. 417, or Abr. viii. 362.

Air-LEVEL, that which ſhews the line of Level by means of a bubble of air incloſed with ſome fluid in a glaſs tube of an indeterminate length and thickneſs, and having its two ends hermetically ſealed: an invention, it is ſaid, of M. Thevenot. When the bubble fixes itſelf at a certain mark, made exactly in the middle of the tube, the caſe or ruler in which it is fixed, is then level. When it is not level, the bubble will riſe to one end.—This glaſs-tube may be ſet in another of braſs, having an aperture in the middle, where the bubble of air may be obſerved.—The liquor with which the tube is filled, is oil of tartar, or aqua ſecunda; thoſe not being liable to freeze as common water, nor to rarefaction and condenſation as ſpirit of wine is.

There is one of theſe inſtruments with ſights, being an improvement upon that laſt deſcribed, which, by the addition of other apparatus, becomes more exact and commodious It conſiſts of an air-Level, n° 1, (*fig.* 1, *Plate XIV*) about 8 inches long, and about two thirds of an inch in diameter, ſet in a braſs tube, 2, having an aperture in the middle, C. The tubes are carried in a ſtrong ſtraight ruler, of a foot long; at the ends of which are fixed two ſights, 3, 3, exactly perpendicular to the tubes, and of an equal height, having a ſquare hole, formed by two fillets of braſs croſſing each other at right angles; in the middle of which is drilled a very ſmall hole, through which a point on a level with the inſtrument is ſeen. The braſs tube is faſtened to the ruler by means of two ſcrews; the one of which, marked 4, ſerves to raiſe or depreſs the tube at pleaſure, for bringing it towards a level. The top of the ball and ſocket is rivetted to a ſmall ruler that ſprings, one end of which is faſtened with ſprings to the great ruler, and at the other end is a ſcrew, 5, ſerving to raiſe and depreſs the inſtrument when nearly level.

But this inſtrument is ſtill leſs commodious than the following one: for though the holes be ever ſo ſmall, yet they will ſtill take in too great a ſpace to determine the point of Level preciſely.

Fig. 2, is a *Level with Telescopic Sights*, first invented by Mr. Huygens. It is like the last; with this difference, that instead of plain sights, it carries a telescope, to determine exactly a point of Level at a considerable distance. The screw 3, is for raising or lowering a little fork, for carrying the hair, and making it agree with the bubble of air when the instrument is Level; and the screw 4, is for making the bubble of air, D or E, agree with the telescope. The whole is fitted to a ball and socket, or otherwise moved by joints and screws.—It may be observed that a telescope may be added to any kind of Level, by applying it upon, or parallel to, the base or ruler, when there is occasion to take the level of remote objects: and it possesses this advantage, that it may be inverted by turning the ruler and telescope half round; and if then the hair cut the same point that it did before, the operation is just. Many varieties and improvements of this instrument have been made by the more modern opticians.

Dr. Desaguliers proposed a machine for taking the difference of Level, which contained the principles both of a barometer and thermometer; but it is not accurate in practice: Philos. Trans. vol. xxxiii. pa. 165, or Abr. vol. vi. 271. *Fig.* 3, 4, 5, 6.

Mr. Hadley too has contrived a Spirit Level to be fixed to a quadrant, for taking a meridian altitude at sea, when the horizon is not visible. See the description and figure of it in the Philos. Trans. vol. xxxviii. 167, or Abr. viii. 357. Various other Spirit Levels, and Mercurial Levels, are also invented and used upon different occasions.

Reflecting LEVEL, that made by means of a pretty long surface of water, representing the same object inverted, which we see erect by the eye; so that the point where these two objects appear to meet, is on a Level with the place where the surface of the water is found. This is the invention of M. Mariotte.

There is another reflecting Level, consisting of a polished metal mirror, placed a little before the object glass of a telescope, suspended perpendicularly. This mirror must be set at an angle of 45 degrees; in which case the perpendicular line of the telescope becomes a horizontal line, or a line of Level. Which is the invention of M. Cassini.

Artillery Foot-LEVEL, is in form of a square (fig. 7), having its two legs or branches of an equal length; at the junction of which is a small hole, by which hangs a plummet playing on a perpendicular line in the middle of a quadrant, which is divided both ways from that point into 45 degrees.

This instrument may be used on other occasions, by placing the ends of its two branches on a plane; for when the plummet plays perpendicularly over the middle division of the quadrant, the plane is then Level.

To use it in Gunnery, place the two ends on the piece of artillery, which may be raised to any proposed height, by means of the plummet, which will cut the degree above the Level. But this supposes the outside of the cannon is parallel to its axis, which is not always the case; and therefore they use another instrument now, either to set the piece Level, or elevate it at any angle; namely a small quadrant, with one of its radii continued out pretty long, which being put into the inside of the cylindrical bore, the plummet shews the angle of elevation, or the line of Level. See *Gunner's* QUADRANT.

Carpenter's, *Bricklayer's*, or *Pavior's* LEVEL, consists of a long ruler, in the middle of which is fitted at right angles another broader piece, at the top of which is fastened a plummet, which when it hangs over the middle line of the 2d or upright piece, shews that the base or long ruler is horizontal or Level. Fig. 8.

Mason's LEVEL, is composed of 3 rules, so jointed as to form an isosceles triangle, somewhat like a Roman A; from the vertex of which is suspended a plummet, which hangs directly over a mark in the middle of the base, when this is horizontal or Level. Fig. 8.

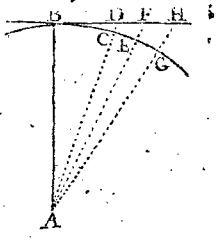
Plumb or Pendulum LEVEL, said to be invented by M. Picard; fig. 10. This shews the horizontal line by means of another line perpendicular to that described by a plummet or pendulum. This Level consists of two legs or branches, joined at right angles, the one of which, of about 18 inches long, carries a thread and plummet; the thread being hung near the top of the branch, at the point 2. The middle of the branch where the thread passes is hollow, so that it may hang free every where: but towards the bottom, where there is a small blade of silver, on which a line is drawn perpendicular to the telescope, the said cavity is covered by two pieces of brass, with a piece of glass G, to see the plummet through, forming a kind of case, to prevent the wind from agitating the thread. The telescope, of a proper length, is fixed to the other leg of the instrument, at right angles to the perpendicular, and having a hair stretched horizontally across the focus of the object-glass, which determines the point of Level, when the string of the plummet hangs against the line on the silver blade. The whole is fixed by a ball and socket to its stand.

Fig. 12, is a *Balance* LEVEL; which being suspended by the ring, the two sights, when in equilibrio, will be horizontal, or in a Level.

Some other Levels are also represented in plate xiv.

LEVELLING, the art or act of finding a line parallel to the horizon at one or more stations, to determine the height or depth of one place with respect to another; for laying out grounds even, regulating descents, draining morasses, conducting water, &c.

Two or more places are on a true level when they are equally distant from the centre of the earth. Also one place is higher than another, or out of level with it, when it is farther from the centre of the earth: and a line equally distant from that centre in all its points, is called the *line of true level*. Hence, because the earth is round, that line must be a curve, and make a part of the earth's circumference, or at least parallel to it, or concentrical with it; as the line BCFG, which has all its points equally distant from A the centre of the earth; considering it as a perfect globe.



But the line of sight BDE &c given by the operations of levels, is a tangent, or a right line perpendicular to the *semidiameter* of the earth at the point of contact B, rising always higher above the true line of level, the

the farther the diſtance is, is called the *apparent line of level.* Thus, CD is the height of the apparent level above the true level, at the diſtance BC or BD; alſo EF is the exceſs of height at F; and GH at G; &c. The difference, it is evident, is always equal to the exceſs of the ſecant of the arch of diſtance above the radius of the earth.

The common methods of levelling are ſufficient for laying pavements of walks, or for conveying water to ſmall diſtances, &c: but in more extenſive operations, as in levelling the bottoms of canals, which are to convey water to the diſtance of many miles, and ſuch like, the difference between the true and the apparent level muſt be taken into the account.

Now the difference CD between the true and apparent level, at any diſtance BC or BD, may be found thus: By a well known property of the circle $2AC + CD : BD :: BD : CD$; or becauſe the diameter of the earth is ſo great with reſpect to the line CD at all diſtances to which an operation of levelling commonly extends, that $2AC$ may be ſafely taken for $2AC + CD$ in that proportion without any ſenſible error, it will be $2AC : BD :: BD : CD$ which therefore is $= \frac{BD^2}{2AC}$ or $\frac{BC^2}{2AC}$ nearly; that is, the difference between the true and apparent level, is equal to the ſquare of the diſtance between the places, divided by the diameter of the earth; and conſequently it is always proportional to the ſquare of the diſtance.

Now the diameter of the earth being nearly 7958 miles; if we firſt take BC = 1 mile, then the exceſs $\frac{BC^2}{2AC}$ becomes $\frac{1}{7958}$ of a mile, which is 7·962 inches, or almoſt 8 inches, for the height of the apparent above the true level at the diſtance of one mile. Hence, proportioning the exceſſes in altitude according to the ſquares of the diſtances, the following Table is obtained, ſhewing the height of the apparent above the true level for every 100 yards of diſtance on the one hand, and for every mile on the other.

By means of theſe Tables of reductions, we can now level to almoſt any diſtance at one operation, which the ancients could not do but by a great multitude; for, being unacquainted with the correction anſwering to any diſtance, they only levelled from one 20 yards to another, when they had occaſion to continue the work to ſome conſiderable extent.

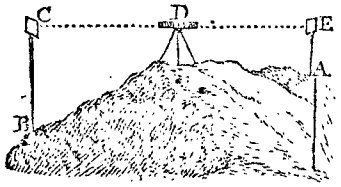
This table will anſwer ſeveral uſeful purpoſes. Thus, firſt, to find the height of the apparent level above the true, at any diſtance. If the given diſtance be contained in the table, the correction of level is found on the ſame line with it: thus at the diſtance of 1000 yards, the correction is 2·57, or two inches and a half nearly; and at the diſtance of 10 miles, it is 66 feet 4 inches. But if the exact diſtance be not found in the table, then multiply the ſquare of the diſtance in yards by 2·57, and divide by 1000000, or cut off 6 places on the right for decimals; the reſt are inches: or multiply the ſquare of the diſtance in miles by 66 feet 4 inches, and divide by 100. 2ndly, To find the extent of the viſible horizon, or how far can be ſeen from any given height, on a horizontal plane, as at ſea, &c. Suppoſe the eye of an obſerver, on the top of a ſhip's maſt at ſea, be at the height of 130 feet above the water, he will then ſee about 14 miles all around. Or from the top of a cliff by the ſea-ſide, the height of which is 66 feet, a perſon may ſee to the diſtance of near 10 miles on the ſurface of the ſea. Alſo, when the top of a hill, or the light in a lighthouſe, or ſuch like, whoſe height is 130 feet, firſt comes into the view of an eye on board a ſhip; the table ſhews that the diſtance of the ſhip from it is 14 miles, if the eye be at the ſurface of the water; but if the height of the eye in the ſhip be 80 feet, then the diſtance will be increaſed by near 11 miles, making in all about 25 miles, diſtance.

3dly, Suppoſe a ſpring to be on one ſide of a hill, and a houſe on an oppoſite hill, with a valley between them; and that the ſpring ſeen from the houſe appears by a levelling inſtrument to be on a level with the foundation of the houſe, which ſuppoſe is at a mile diſtance from it; then is the ſpring 8 inches above the true level of the houſe; and this difference would be barely ſufficient for the water to be brought in pipes from the ſpring to the houſe, the pipes being laid all the way in the ground.

4th, If the height or diſtance exceed the limits of the table: Then, firſt, if the diſtance be given, divide it by 2, or by 3, or by 4, &c, till the quotient come within the diſtances in the table; then take out the height anſwering to the quotient, and multiply it by the ſquare of the diviſor, that is by 4, or 9, or 16, &c, for the height required: So if the top of a hill be juſt ſeen at the diſtance of 40 miles: then 40 divided by 4 gives 10, to which in the table anſwers 66⅔ feet, which being multiplied by 16, the ſquare of 4, gives 1061⅓ feet for the height of the hill. But when the height is given, divide it by one of theſe ſquare numbers 4, 9, 16, 25, &c, till the quotient come within the limits of the table, and multiply the quotient by the ſquare root of the diviſor, that is by 2, or 3, or 4, or 5, &c, for the diſtance ſought: So when the top of the pike of Teneriff, ſaid to be almoſt 3 miles or 15840 feet high, juſt comes into view at ſea; divide 15840 by 225, or the ſquare of 15, and the quotient

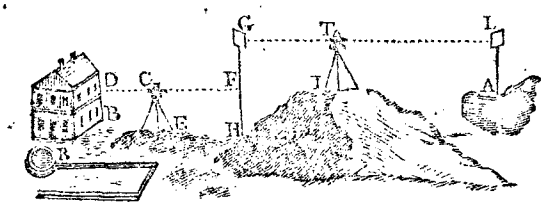
is 70 nearly; to which in the table anſwers, by proportion, nearly $10\frac{5}{7}$ miles; then multiplying $10\frac{5}{7}$ by 15, gives 154 miles and $\frac{2}{7}$, for the diſtance of the hill.

Of the Practice of Levelling.



The operation of Levelling is as follows. Suppoſe the height of the point A on the top of a mountain, above that of B, at the foot of it, be required. Place the level about the middle diſtance at D, and ſet up pickets, poles, or ſtaffs, at A and B, where perſons muſt attend with ſignals for raiſing and lowering, on the ſaid poles, little marks of paſteboard or other matter. The level having been placed horizontally by the bubble, &c, look towards the ſtaff AE, and cauſe the perſon there to raiſe or lower the mark, till it appear through the teleſcope, or ſights, &c, at E: then meaſure exactly the perpendicular height of the point E above the point A, which ſuppoſe 5 feet 8 inches, ſet it down in your book. Then turn your view the other way, towards the pole B, and cauſe the perſon there to raiſe or lower his mark, till it appear in the viſual line as before at C; and meaſuring the height of C above B, which ſuppoſe 15 feet 6 inches, ſet this down in your book alſo, immediately above the number of the firſt obſervation. Then ſubtract the one from the other, and the remainder 9 feet 10 inches, will be the difference of level between A and B, or the height of the point A above the point B.

If the point D, where the inſtrument is fixed, be exactly in the middle between the points A and B, there will be no neceſſity for reducing the apparent level to the true one, the viſual ray on both ſides being raiſed equally above the true level. But if not, each height muſt be corrected or reduced according to its diſtance, before the one corrected height is ſubtracted from the other; as in the caſe following.



When the diſtance is very conſiderable, or irregular, ſo that the operation cannot be effected at once placing of the level; or when it is required to know if there be a ſufficient deſcent for conveying water from the ſpring A to the point B; it will be neceſſary to perform this at ſeveral operations. Having choſen a proper place for the firſt ſtation, as at I, fix a pole at the point A near the ſpring, with a proper mark to ſlide up and down it, as L; and meaſure the diſtance from A to I. Then the level being adjuſted in the point I, let the mark L be raiſed or lowered till it is ſeen through the teleſcope or ſights of the level, and meaſure the height AL. Then having fixed another pole at H, direct the level to it, and cauſe the mark G to be moved up or down till it appear through the inſtrument: then meaſure the height GH, and the diſtance from I to H; noting them down in the book. This done, remove the level forwards to ſome other eminence as E, from whence the pole H may be viewed, as alſo another pole at D; then having adjuſted the level in the point E, look back to the pole H; and managing the mark as before, the viſual ray will give the point F; then meaſuring the diſtance HE and the height HF, note them down in the book. Then, turning the level to look at the next pole D, the viſual ray will give the point D; there meaſure the height of D, and the diſtance EB, entering them in the book as before. And thus proceed from one ſtation to another, till the whole is completed.

But all theſe heights muſt be corrected or reduced by the foregoing table, according to their reſpective diſtances; and the whole, both diſtances and heights, with their corrections, entered in the book in the following manner.

Back-ſights.				*Fore-ſights.*			
Diſts.	Hts.		Cors.	Diſts.	Hts.		Cors.
yds	ft	in.	inc.	yds	ft.	in.	inc.

		9·2		2590			6·1
	21	0·8		Diſt. 4755	26	11·9	
					21	0·8	
				Whole Dif. of level	5	11·1	

Having ſummed up all the columns, add thoſe of the diſtances together, and the whole diſtance from A to B is 4755 yards, or 2 miles and 3 quarters nearly. Then, the ſums of the corrections taken from the ſums of the apparent heights, leave the two corrected heights; the one of which being taken from the other, leaves 5 feet 11·1 inc. for the true difference of level ſought between the two places A and B, which is at the rate of an inch and half nearly to every 100 yards, a quantity more than ſufficient to cauſe the water to run from the ſpring to the houſe.

Or, the operation may be otherwiſe performed, thus: Inſtead of placing the level between every two poles, and taking both back-ſights and fore-ſights; plant it firſt at the ſpring A, and from thence obſerve the level to the firſt pole; then remove it to this pole, and obſerve the 2d pole; next move it to the 2d pole, and obſerve the 3d pole; and ſo on, from one pole to another, always taking foreward ſights or obſervations only. And then at the laſt, add all the corrected heights together,

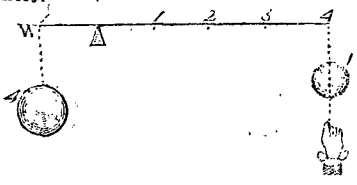
gether, and the ſum will be the whole difference of level ſought.

Dr. Halley ſuggeſted a new method of levelling performed wholly by means of the barometer, in which the mercury is found to be ſuſpended at ſo much the leſs height, as the place is farther remote from the centre of the earth; and hence the different heights of the mercury in two places give the difference of level. This method is, in fact, no other than the method of meaſuring altitudes by the barometer, which has lately been ſo ſucceſsfully practiſed and perfected by M. De Luc and others; but though it ſerves very well for the heights of hills, and other conſiderable altitudes, it is not accurate enough for determining ſmall altitudes, to inches and parts. See the Barometrical Meaſurement of Altitudes.

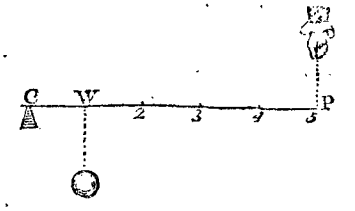
Levelling *Poles*, or *Staves*, are inſtruments uſed in levelling, ſerving to carry the marks to be obſerved, and at the ſame time to meaſure the heights of thoſe marks from the ground. They uſually conſiſt each of two long wooden rulers, made to ſlide over each other, and divided into feet and inches, &c.

LEVER, a ſtraight bar of iron or wood, &c, ſuppoſed to be inflexible, ſupported on a fulcrum or prop by a ſingle point, about which all the parts are moveable.

The Lever is the firſt of thoſe ſimple machines called *mechanical powers*, as being the ſimpleſt of them all; and is chiefly uſed for raiſing great weights to ſmall heights.

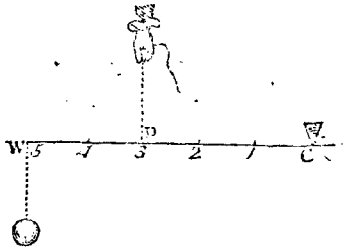


The Lever is of three kinds. Firſt the common ſort, where the weight intended to be raiſed is at one end of it, our ſtrength or another weight called the power is at the other end, and the prop or fulcrum is between them both. In ſtirring up the fire with a poker, we make uſe of this Lever; the poker is the Lever, it reſts upon one of the bars of the grate as a prop, the incumbent fire is the weight to be overcome, and the preſſure of the hand on the other end is the force or power. In this, as in all the other machines, we have only to increaſe the diſtance between the force and the prop, or to decreaſe the diſtance between the weight and the prop, to give the operator the greater power or effect. To this kind of Lever may alſo be referred all ſciſſars, pincers, ſnuffers, &c. The ſteel-yard and the common balance are alſo Levers of this kind.



In the Lever of the 2d kind the prop is at one end, the force or power at the other, and the weight to be raiſed is between them. Thus, in raiſing a water-plug in the ſtreets, the workman puts his iron bar or Lever through the ring or hole of the plug, till the end of it reaches the ground on the other ſide; then making that the prop, he lifts the plug with his force or ſtrength at the other end of the Lever. In this Lever too, the nearer the weight is to the prop, or the farther the power from the prop, the greater is the effect. To this 2d kind of Lever may alſo be referred the oars and rudder of a boat, the maſts of a ſhip, cutting knives fixed at one end, and doors, whoſe hinges ſerve as a fulcrum.

In the Lever of the third kind, the power acts between the weight and the prop; ſuch as a ladder raiſed by a man ſomewhere between the two ends, to rear it againſt a wall, or a pair of tongs, &c.



It is by this kind of Lever too that the muſcular motions of animals are performed, the muſcles being inſerted much nearer to the centre of motion, than the point where is placed the centre of gravity of the weight to be raiſed; ſo that the power of the muſcle is many times greater than the weight it is able to ſuſtain. And in this third kind of Lever, to produce a balance between the power and weight, the power or force muſt *exceed* the weight, in the ſame proportion as it is nearer the prop than the weight is; whereas in the other two kinds, the power is leſs than the weight, in the ſame proportion as its diſtance is greater; that is, univerſally, the power and weight are each of them reciprocally as their diſtance from the prop; as is demonſtrated below.

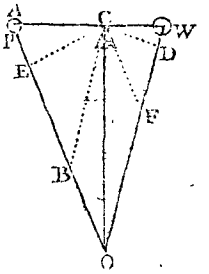
Some authors make a 4th ſort of what is called a bended Lever; ſuch as a hammer in drawing a nail, &c.

In all Levers, the univerſal property is, that the effect of either the weight or the power, to turn the Lever about the fulcrum, is directly as its intenſity and its diſtance from the prop, that is as di, where d denotes the diſtance, and i the intenſity, ſtrength, or weight, &c, of the agent. For it is evident that at a double diſtance it will have a double effect, at a triple diſtance a triple effect, and ſo on; alſo that a double intenſity produces a double effect, a triple a triple, and ſo on: therefore univerſally the effect is as di the product of the two. In like manner, if D be the diſtance of another power or agent, whoſe intenſity is I, then is DI the effect of this alſo to move the Lever. And if theſe two agents act againſt each other on the Lever, and their effects be ſuppoſed equal, or the Lever kept in equilibrio by the equal and contrary effects of theſe two agents; then is $DI = di$, which equation reſolves into this analogy, viz, $D : d :: i : I$; that is, the diſtances of the agents from the prop, are reciprocally

as

or inverſely as their intenſities, or the power is to the weight, as the diſtance of the latter is to the diſtance of the former.

Writers on mechanics commonly demonſtrate this proportion in a very abſurd manner, viz, by ſuppoſing the Lever put into motion about the prop, and then inferring that, becauſe the momenta of two bodies are equal, when placed upon the Lever at ſuch diſtances, that theſe diſtances are reciprocally proportional to the weights of the bodies, that therefore this is alſo the proportion in caſe of an equilibrium; which is an attempt abſurdly to demonſtrate a thing ſuppoſing the contrary, that a body is at reſt, by ſuppoſing it to be in motion. I ſhall therefore give here a new and univerſal demonſtration of the property, on the pure principles of reſt and preſſure, or force only. Thus, let PW be a lever,



C the prop, and P and W any two forces acting on the lever at the points P and W, in the directions PO, WO; then if CE and CD be the perpendicular diſtances of the directions of theſe forces from the prop C, it is to be demonſtrated that P : W :: CD : CE. In order to which join CO, and draw CB parallel to WO, and CF parallel to PO. Then will CO be the direction of the preſſure on the prop, otherwiſe there could not be an equilibrium, for the directions of three forces that keep each other in equilibrium, muſt neceſſarily meet in the ſame point. And becauſe any three forces that keep each other in equilibrium, are proportional to the three ſides of a triangle formed by drawing lines parallel to the directions of theſe forces; therefore the forces on P, C, and W, are as the three lines BO, CO, CB, which are in the ſame direction, or parallel to them; that is the force P is to the force W, as BO or its equal CF is to CB. But the two triangles CDF, CEB are ſimilar, and have their like ſides proportional,

viz, CF : CB :: CD : CE;

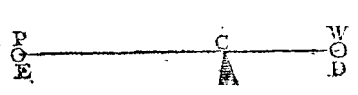
and becauſe it was CF : CB :: P : W;

therefore by equality P : W :: CD : CE;

that is, each force is reciprocally proportional to the diſtance of its direction from the fulcrum. And it will be found that this demonſtration will ſerve alſo for the other kinds of Levers, by drawing the lines as directed. Hence if any given force P be applied to a Lever at A; its effect upon the Lever, to turn it about the centre of motion C, is as the length of the arm CA, and the ſine of the angle of direction CAE. For the perp. CE is as CA × ſin. ∠A.

In any analogy, becauſe the product of the extremes is equal to that of the means; therefore the product of the power by the diſtance of its direction is equal to the product of the weight by the diſtance of its direction. That is, P × CE = W × CD.

If the Lever, with the two weights fixed to it, be made to move about the centre C; the momentum of the power will be equal to that of the weight; and the weights will be reciprocally proportional to their velocities.



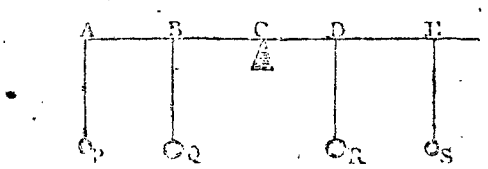
When the two forces act perpendicularly on the Lever, as two weights &c; then, in caſe of an equilibrium, E coincides with P, and D with W; and the diſtances CP, CW, taken on the Lever, or the diſtances of the power and weight, from the fulcrum, are reciprocally proportional to the power and weight.

In a ſtraight Lever, kept in equilibrio by a weight and power acting perpendicularly upon it; then, of theſe three, the power, weight, and preſſure on the prop, any one is as the diſtance of the other two.

And hence too P + W : P :: ED : CD,

and P + W : W :: ED : CP;

that is, the ſum of the weights is to either of them, as the ſum of their diſtances is to the diſtance of the other.



Alſo, if ſeveral weights P, Q, R, S, &c, act on a ſtraight Lever, and keep it in equilibrio; then the ſum of the products on one ſide of the prop, will be equal to the ſum on the other ſide, made by multiplying each weight by its diſtance from the prop; viz, P . AC + Q . BC = R . DC + S . EC + &c.

Hitherto the Lever has been conſidered as a mathematical line void of weight or gravity. But when its weight is conſidered, it is to be done thus: Find the weight and the centre of gravity of the Lever alone, and then conſider it as a mathematical line, but having an equal weight ſuſpended by that centre of gravity; and ſo combine its effect with thoſe of the other weights, as above.

Upon the foregoing principles depends the nature of ſcales and beams for weighing all bodies. For, if the diſtances be equal, then will the weights be equal alſo; which gives the conſtruction of the common ſcales. And the Roman ſtatera, or ſteel-yard, is alſo a Lever, but of unequal arms or diſtances, ſo contrived that one weight only may ſerve to weigh a great many, by ſliding it backwards and forwards to different diſtances upon the longer arm of the Lever. See BALANCE, &c.

Alſo upon the principle of the Lever depends almoſt all other mechanical powers and effects. See WHEEL-AND-AXLE, PULLEY, WEDGE, SCREW, &c.

LEVITY, the privation or want of weight in any body, when compared with another that is heavier; and in this ſenſe it is oppoſed to gravity. Thus cork, and moſt ſorts of wood that float in water, have Levity with reſpect to water, that is, are leſs heavy. The ſchools maintained that there is ſuch a thing as poſitive and abſolute Levity; and to this they imputed the riſe and buoyancy of bodies lighter in ſpecie than the bodies in which they riſe and float. But it is now well known that this happens only in conſequence of the heavier and denſer fluid, which, by its ſuperior gravity, gains the loweſt place, and raiſes up the lighter body by a force which is equal to the difference of their gravities. It was demonſtrated by Archimedes, that a ſolid body will float any where in a fluid of the ſame ſpecific gravity;

gravity; and that a lighter body will always be raiſed up in it.

LEUWENHOEK (Antony), a celebrated Dutch philoſopher, was born at Delft in 1632; and acquired a great reputation throughout all Europe, by his experiments and diſcoveries in Natural Hiſtory, by means of the microſcope. He particularly excelled in making glaſſes for microſcopes and ſpectacles; and he was a member of moſt of the literary ſocieties of Europe; to whom he ſent many memoirs. Thoſe in the Philoſophical Tranſactions, and in the Paris Memoirs, extend through many volumes; the former were extracted, and publiſhed at Leyden, in 1722. He died in 1723, at 91 years of age.

LEYDEN Phial, in Electricity, is a glaſs phial or jar, coated both within and without with tin foil, or ſome other conducting ſubſtance, that it may be charged, and employed in a variety of uſeful and entertaining experiments. Or even flat glaſs, or any other ſhape, ſo coated and uſed, has alſo received the ſame denomination. Alſo a vacuum produced in ſuch a jar, &c. has been named the *Leyden Vacuum*.

The Leyden Phial has been ſo called, becauſe it is ſaid that M. Cunæus, a native of Leyden, firſt contrived, about the cloſe of the year 1745, to accumulate the electrical power in glaſs, and uſe it in this way. But Dr. Prieſtley aſſerts that this diſcovery was firſt made by Von Kleiſt, dean of the cathedral in Camin; who, on the 4th of November 1745, ſent an account of it to Dr. Lieberkuhn at Berlin: however, thoſe to whom Kleiſt's account was communicated, could not ſucceed in performing his experiments. The chief circumſtances of this diſcovery are ſtated by Dr. Prieſtley in the following manner.

Profeſſor Muſſchenbroek and his friends, obſerving that electrified bodies, when expoſed to the common atmoſphere, which is always replete with conducting particles of various kinds, ſoon loſt the moſt part of their electricity, imagined that if the electrified bodies ſhould be terminated on all ſides by original electrics, they might be capable of receiving a ſtronger power, and retaining it a longer time. Glaſs being the moſt convenient electric for this purpoſe, and water the moſt convenient non-electric, they at firſt made theſe experiments with water in glaſs bottles: but no conſiderable diſcovery was made, till M. Cunæus, happening to hold his glaſs veſſel in one hand, containing water, which had a communication with the prime conductor by means of a wire; and with the other hand diſengaging it from the conductor, when he ſuppoſed the water had received as much electricity as the machine could give it, was ſurpriſed by a ſudden and unexpected ſhock in his arms and breaſt. This experiment was repeated, and the firſt accounts of it publiſhed in Holland by Meſſrs. Allamand and Muſſchenbroek; by the Abbé Nollet and M. Monnier, in France; and by Meſſrs. Gralath and Rugger, in Germany. M. Gralath contrived to increaſe the ſtrength of the ſhock, by altering the ſhape and ſize of the phial, and alſo by charging ſeveral phials at the ſame time, ſo as to form what is now called the *electrical battery*. He likewiſe made the ſhock to paſs through a number of perſons connected in a circuit from the outſide to the inſide of the phial. He alſo obſerved that a cracked phial would not receive a charge: and he diſcovered what is now called the *Reſiduum of a charge*.

Dr. Watſon, about this time, obſerved a circumſtance attending the operation of charging the phial, which, if purſued, might have led him to the diſcovery which was afterwards made by Dr. Franklin. He ſays, that when the phial is well electrified, and you apply your hand to it, you ſee the fire flaſh from the outſide of the glaſs, wherever you touch it, and it crackles in your hand. He alſo obſerved, that when a ſingle wire only was faſtened about a phial, properly filled with warm water, and charged; upon the inſtant of its exploſion, the electrical corruſcations were ſeen to dart from the wire, and to illuminate the water contained in the phial. He likewiſe found that the ſtroke, in the diſcharge of the phial, was, *cæteris paribus*, as the points of contact of the non-electrics of the outſide of the glaſs; which led to the method of coating glaſs: in conſequence of which he made experiments, from whence he concluded, that the effect of the Leyden phial was greatly increaſed by, if not chiefly owing to, the number of points of non-electric in contact within the glaſs, and the denſity of the matter of which theſe points conſiſted; provided the matter was, in its own nature, a ready conductor of electricity. He farther obſerved, that the exploſion was greater from hot water incloſed in glaſſes, than from cold, and from his coated jars warmed, than when cold.

Mr. Wilſon, in 1746, diſcovered a method of giving the ſhock to any particular part of the body, without affecting the reſt. He alſo increaſed the ſtrength of the ſhock by plunging the phial in water, which gave it a coat of water on the outſide as high as it was filled within. He likewiſe found, that the law of accumulation of the electric matter in the Leyden phial, was always in proportion to the thinneſs of the glaſs, the ſurface of the glaſs, and that of the non-electrics in contact with its outſide and inſide. He made alſo a variety of other experiments with the Leyden phial, too long here to be related.

Mr. Canton found, that when a charged phial was placed upon electrics, the wire and coating would give a ſpark or two alternately, and that by a continuance of the operation the phial would be diſcharged; though he did not obſerve that theſe alternate ſparks proceeded from the two contrary electricities diſcovered by Dr. Franklin.

The Abbé Nollet made ſeveral experiments with this phial. He received a ſhock from one, out of which the air had been exhauſted, and into which the end of his conductor had been inſerted. He aſcribed the force of the glaſs, in giving a ſhock, to that property of it, by which it retains it more ſtrongly than conductors do, and is not ſo eaſily diveſted of it as they are. It was he alſo who firſt tried the effect of the electric ſhock on brute animals: and he enlarged the circuit of its conveyance.

M. Monnier, it has been ſaid, was the firſt who diſcovered that the Leyden phial would retain its electricity for a conſiderable time after it was charged; and that in time of froſt he found it continued for 36 hours. It is remarkable too that both the French and Engliſh philoſophers made ſeveral experiments, which, with a ſmall degree of attention, would have led them to the diſcovery of the different qualities of the electricity on

the contrary ſides of the glaſs. But this diſcovery was reſerved for the ingenious Dr. Franklin; who, in explaining the method of charging the Leyden phial, obſerves, that when one ſide of the glaſs is electrified plus, or poſitively, the other ſide is electrified minus, or negatively: ſo that whatever quantity of fire is thrown upon one ſide of the glaſs, the ſame quantity is drawn out of the other; and in an uncharged phial, none can be thrown into the inſide, when none can be taken from the outſide; and that there is really no more electric fire in the phial after it is charged than before; all that can be done by charging, being only to take from one ſide, and convey to the other. Dr. Franklin alſo obſerved that glaſs was not impervious to electricity, and that as the equilibrium could not be reſtored to the charged phial by any internal communication, it muſt neceſſarily be done by conductors externally joining the inſide and the outſide. Theſe capital diſcoveries he made by obſerving, that when a phial was charged, a cork ball ſuſpended by ſilk, was attracted by the outſide coating, when it was repelled by a wire communicating with the inſide, and *vice verſâ*. But the truth of this principle appeared more evident, when he brought the knob of the wire, communicating with the outſide coating, within a few inches of the wire communicating with the inſide coating, and ſuſpended a cork ball between them; for then the ball was attracted by them alternately, till the phial was diſcharged.

Dr. Franklin alſo ſhewed, that when the phial was charged, one ſide loſt exactly as much as the other gained, in reſtoring the equilibrium. Hanging a fine linen thread near the coating of an electrical phial, he obſerved that whenever he brought his finger near the wire, the thread was attracted by the coating; for as the fire was drawn from the inſide by touching the wire, the outſide drew in an equal quantity by the thread. He likewiſe proved, that the coating on one ſide of a phial received juſt as much electricity, as was emitted from the diſcharge of the other, and that in the following manner:—He inſulated his rubber, and then hanging a phial to his conductor, he found it could not be charged, even when his hand was held conſtantly to it; becauſe, though the electric fire might leave the outſide of the phial, there was none collected by the rubber to be conveyed to the inſide. He then took away his hand from the phial, and forming a communication by a wire from the outſide coating to the inſulated rubber, he found that it was charged with eaſe. In this caſe it was plain, that the very ſame fire which left the outſide coating, was conveyed to the inſide by the way of the rubber, the globe, the conductor, and the wire of the phial. This new theory of charging the Leyden phial, led Dr. Franklin to obſerve a greater variety of facts, relating both to the charging and diſcharging it, than other philoſophers had attended to. And this maxim, that it takes in at one ſurface, what it loſes at the other, led Dr. Franklin to think of charging ſeveral phials together with the ſame trouble, by connecting the outſide of one with the inſide of another; by which the fire that was driven out of the firſt would be received by the ſecond, &c. By this means he found, that a great number of jars might be charged with the ſame labour as one only; and that they might be charged equally high, were it not that every one of them receives the new fire, and loſes its old, with ſome reluctance, or rather that it gives ſome ſmall reſiſtance to the charging. And on this principle he firſt conſtructed an electrical battery.

When Dr. Franklin firſt began his experiments on the Leyden phial, he imagined that the electric fire was all crowded into the ſubſtance of the non-electric, in contact with the glaſs. But he afterwards found, that its power of giving a ſhock lay in the glaſs itſelf, and not in the coating, by the following ingenious analyſis of the phial. To find where the ſtrength of the charged bottle lay, having placed it upon a glaſs, he firſt took out the cork and the wire; but not finding the virtue in them, he touched the outſide coating with one hand, and put a finger of the other into the mouth of the bottle; when the ſhock was felt quite as ſtrong as if the cork and wire had been in it. He then charged the phial again, and pouring out the water into an empty bottle which was inſulated, he expected that if the force reſided in the water, it would give the ſhock; but he found it gave none. He therefore concluded that the electric fire muſt either have been loſt in decanting, or muſt remain in the bottle; and the latter he found to be true; for, upon filling the charged bottle with freſh water, he found the ſhock, and was ſatisfied that the power of giving it reſided in the glaſs itſelf. The ſame experiment was made with panes of glaſs, laying the coating on lightly, and charging it, as the water had been before charged in the bottle, when the reſult was preciſely the ſame. He alſo proved in other ways that the electric fire reſided in the glaſs. See Franklin's Letters and Obſervations, &c. Alſo Prieſtley's Hiſt. of Electricity, vol. i, pa. 191, &c.

From this account of Dr. Franklin's method of analyzing the Leyden phial, the manner of charging and diſcharging it, with the reaſon of the proceſs, are eaſily underſtood. Thus, placing a coated phial near the prime conductor, ſo that the knob of its wire may be in contact with it; then upon turning the winch of the machine, the index of the electrometer, E, fixed to the conductor, will gradually riſe as far as 90° nearly, and there reſt; which ſhews that the phial has received its full charge: then holding the diſcharger by its glaſs handle, and applying one of its knobs to the outſide coating of the phial, the other being brought near the knob of the wire, or near the prime conductor which communicates with it, a report will be heard, and luminous ſparks will be ſeen between the diſcharger and the conducting ſubſtances communicating with the ſides of the phial; and by this operation the phial will be diſcharged. But, inſtead of uſing the diſcharger, if a perſon touch the outſide of the phial with one hand, and bring the other hand near the wire of the phial, the ſame ſpark and report will take place, and a ſhock will be felt, affecting the wriſts and elbows, and the breaſt too when the ſhock is ſtrong: a ſhock may alſo be given to any ſingle part of the body, if that part alone be brought into the circuit. If a number of perſons join hands, and the firſt of them touch the outſide of the phial, while the laſt touches the wire communicating with the inſide, they will all feel the ſhock at the ſame time. If the coated phial be held by the wire, and the outſide coating be preſented to the prime

conductor, it will be charged as readily; but only with this difference, that in this caſe the outſide will be poſitive, and the inſide negative; alſo if the prime conductor, by being connected with the rubber of the machine, be electrified negatively, the phial will be charged in the ſame manner; but the ſide that touches the conductor will be electrified negatively, and the oppoſite ſide will be electrified poſitively. But, by inſulating the phial, and repeating the ſame proceſs, the index of the electrometer will ſoon riſe to 90°, yet the phial will remain uncharged; becauſe the outſide, having no communication with the earth, &c, cannot part with its own electricity, and therefore the inſide cannot acquire an additional quantity: but when a chain, or any other conductor, connects the outſide of the phial with the table, the phial may be charged as before. Moreover, if a phial be inſulated, and one ſide of it, inſtead of being connected with the earth, be connected with the inſulated rubber, whilſt the other ſide communicates with the prime conductor, the phial will be expeditiouſly charged; becauſe that whilſt the rubber exhauſts one ſide, the other ſide is ſupplied by the prime conductor; and thus the phial is charged with its own electricity; or the natural electric matter of one of its ſides is thus thrown upon the other ſide. This laſt experiment may be diverſified by inſulating the phial, and placing it with its wire at the diſtance of about half an inch from the prime conductor, and holding the knob of another wire at the ſame diſtance from its outſide coating; then, upon turning the machine, a ſpark will be obſerved to proceed from the prime conductor to the wire of the phial, and another ſpark will paſs at the ſame time from the outſide coating to the knob of the wire preſented towards it: and thus it appears that as a quantity of the electric matter is entering the inſide of the phial, an equal quantity of it is leaving the outſide. If the wire preſented to the outſide of the phial be pointed, it will be ſeen illuminated with a ſtar; but if the pointed wire be connected with the coating of the phial, it will appear illuminated with a bruſh of rays. See *Charge*, *Electrical Shock*, *Experiments*, &c.

Mr. Cavallo has deſcribed the conſtruction of a phial which, being charged by an electrical kite, in examining the ſtate of the clouds, or in any other way, may be put into the pocket, and which will retain its charge for a conſiderable time. A phial of this kind has been kept in a charged ſtate for ſix weeks. See his Electricity, pa. 340. Many other curious experiments with the Leyden phial may be ſeen in the books above cited, as alſo in the volumes of the Philoſ. Tranſ. and elſewhere. In this laſt-mentioned work, Mr. Cavallo deſcribes a method of repairing coated phials that have cracked by any means. He firſt removes the outſide coating from the fractured part, and then makes it moderately hot, by holding it to the flame of a candle; and whilſt it remains hot, he applies burning ſealing-wax to the part, ſo as to cover the fracture entirely; obſerving that the thickneſs of this wax coating may be greater than that of the glaſs. Laſtly, he covers all the ſealing-wax, and alſo part of the ſurface of the glaſs beyond it, with a compoſition made with four parts of bees-wax, one of reſin, one of turpentine, and a very little oil of olives; this being ſpread upon a piece of oiled ſilk, he applies it in the manner of a plaſter. In this way ſeveral phials have been ſo effectually repaired, that after being frequently charged, they were at laſt broken by a ſpontaneous diſcharge, but in a different part of the glaſs. Philoſ. Tranſ. vol. 68, pa. 1011.

LIBRA, *Balance*, one of the mechanical powers. See BALANCE.

LIBRA is alſo one of the 48 old conſtellations, and the 7th ſign of the zodiac, being oppoſite to Aries, and marked like a part of a pair of ſcales, thus ♎. The figure of the balance was probably given to this part of the ecliptic, becauſe when the ſun arrives at this part, which is at the time of the autumnal equinox, the days and nights are equal, as if weighed in a balance.

The ſtars in this conſtellation are, according to Ptolomy 17, Tycho 10, Hevelius 20, and Flamſteed 51.

LIBRA alſo denotes the ancient Roman pound, which was divided into 12 unciæ, or ounces, and the ounce into 24 ſcruples. It ſeems the mean weight of the ſcruple was nearly equal to 17½ grains Troy, and conſequently the libra, or pound, 5040 grains. It was alſo the name of a gold coin, equal in value to 20 denarii. See Philoſ. Tranſ. vol. 61, pa. 462.

The French livre is derived from the Roman libra, this being uſed in France for the proportions of their coin till about the year 1100, their ſols being ſo proportioned as that 20 of them were equal to the libra. By degrees it became a term of account, and every thing of the value of 20 ſols was called a livre.

LIBRATION, *of the Moon*, is an apparent irregularity in her motion, by which ſhe ſeems to librate, or waver, about her own axis, one while towards the eaſt, and again another while towards the weſt. See MOON, and EVECTION. Hence it is that ſome parts near the moon's weſtern edge at one time recede from the centre of the diſc, while thoſe on the other or eaſtern ſide approach nearer to it; and, on the contrary, at another time the weſtern parts are ſeen to be nearer the centre, and the eaſtern parts farther from it: by which means it happens that ſome of thoſe parts, which were before viſible, ſet and hide themſelves in the hinder or inviſible ſide of the moon, and afterwards return and appear again on the nearer or viſible ſide.

This Libration of the moon was firſt diſcovered by Hevelius, in the year 1654; and it is owing to her equable rotation round her own axis, once in a month, in conjunction with her unequal motion in the perimeter of her orbit round the earth. For if the moon moved in a circle, having its centre coinciding with the centre of the earth, whilſt it turned on its axis in the preciſe time of its period round the earth, then the plane of the ſame lunar meridian would always paſs through the earth, and the ſame face of the moon would be conſtantly and exactly turned towards us. But ſince the real motion of the moon is about a point conſiderably diſtant from the centre of the earth, that motion is very unequal, as ſeen from the earth, the plane of no one meridian conſtantly paſſing through the earth.

The Libration of the moon is of three kinds.

1ſt, Her libration in longitude, or a ſeeming to-and-again motion according to the order of the ſigns of the zodiac. This libration is nothing twice in each periodical month, viz, when the moon is in her apogeum, and when in her perigeum; for in both theſe caſes the

plane of her meridian, which is turned towards us, is directed alike towards the earth.

2d, Her libration in latitude; which ariſes from hence, that her axis not being perpendicular to the plane of her orbit, but inclined to it, ſometimes one of her poles, and ſometimes the other will nod, as it were, or dip a little towards the earth, and conſequently ſhe will appear to librate a little, and to ſhew ſometimes more of her ſpots, and ſometimes leſs of them, towards each pole. Which libration, depending on the poſition of the moon, in reſpect to the nodes of her orbit, and her axis being nearly perpendicular to the plane of the ecliptic, is very properly ſaid to be in latitude. And this alſo is completed in the ſpace of the moon's periodical month, or rather while the moon is returning again to the ſame poſition, in reſpect of her nodes.

3d, There is alſo a third kind of libration; by which it happens that although another part of the moon be not really turned to the earth, as in the former libration, yet another is illuminated by the ſun. For ſince the moon's axis is nearly perpendicular to the plane of the ecliptic, when ſhe is moſt ſoutherly, in reſpect of the north pole of the ecliptic, ſome parts near to it will be illuminated by the ſun; while, on the contrary, the ſouth pole will be in darkneſs. In this caſe, therefore, if the ſun be in the ſame line with the moon's ſouthern limit, then, as ſhe proceeds from conjunction with the ſun towards her aſcending node, ſhe will appear to dip her northern polar parts a little into the dark hemiſphere, and to raiſe her ſouthern polar parts as much into the light one. And the contrary to this will happen two weeks after, while the new moon is deſcending from her northern limit; for then her northern polar parts will appear to emerge out of darkneſs, and the ſouthern polar parts to dip into it. And this ſeeming libration, or rather theſe effects of the former libration in latitude, depending on the light of the ſun, will be completed in the moon's ſynodical month. Greg. Aſtron. lib. 4, ſect. 10.

LIBRATION *of the Earth*, is a term applied by ſome aſtronomers to that motion, by which the earth is ſo retained in its orbit, as that its axis continues conſtantly parallel to the axis of the world.

This Copernicus calls the *motion of libration*, which may be thus illuſtrated: Suppoſe a globe, with its axis parallel to that of the earth, painted on the flag of a maſt, moveable on its axis, and conſtantly driven by an eaſt wind, while it ſails round an iſland, it is evident that the painted globe will be ſo librated, as that its axis will be parallel to that of the world, in every ſituation of the ſhip.

LIFE-ANNUITIES, are ſuch periodical payments as depend on the continuance of ſome particular life or lives. They may be diſtinguiſhed into Annuities that commence immediately, and ſuch as commence at ſome future period, called *reverſionary life-annuities*.

The value, or preſent worth, of an annuity for any propoſed life or lives, it is evident, depends on two circumſtances, the intereſt of money, and the chance or expectation of the continuance of life. Upon the former only, it has been ſhewn, under the article ANNUITIES, depends the value or preſent worth of an annuity certain, or that is not ſubject to the continuance of a life, or other contingency; but the expectation of life being a thing not certain, but only poſſeſſing a certain chance, it is evident that the value of the certain annuity, as ſtated above, muſt be diminiſhed in proportion as the expectancy is below certainty: thus, if the preſent value of an annuity certain be any ſum, as ſuppoſe 100l. and the value or expectancy of the life be $\frac{1}{2}$, then the value of the life-annuity will be only half of the former, or 50l; and if the value of the life be only $\frac{1}{3}$, the value of the life-annuity will be but $\frac{1}{3}$ of 100l, that is 33l. 6s. 8d; and ſo on.

The meaſure of the value or expectancy of life, depends on the proportion of the number of perſons that die, out of a given number, in the time propoſed; thus, if 50 perſons die, out of 100, in any propoſed time, then, half the number only remaining alive, any one perſon has an equal chance to live or die in that time, or the value of his life for that time is $\frac{1}{2}$; but if $\frac{2}{3}$ of the number die in the time propoſed, or only $\frac{1}{3}$ remain alive, then the value of any one's life is $\frac{1}{3}$; and if $\frac{3}{4}$ of the number die, or only $\frac{1}{4}$ remain alive, then the value of any life is but $\frac{1}{4}$; and ſo on. In theſe proportions then muſt the value of the annuity certain be diminiſhed, to give the value of the like life annuity.

It is plain therefore that, in this buſineſs, it is neceſſary to know the value of life at all the different ages, from ſome table of obſervations on the mortality of mankind, which may ſhew the proportion of the perſons living, out of a given number, at the end of any propoſed time; or from ſome certain hypotheſis, or aſſumed principle. Now various tables and hypotheſes of this ſort were given by the writers on this ſubject, as Dr. Halley, Mr. Demoivre, Mr. Thomas Simpſon, Mr. Dodſon, Mr. Kerſſeboom, Mr. Parcieux, Dr. Price, Mr. Morgan, Mr. Baron Maſeres, and many others. But the ſame table of probabilities of life will not ſuit all places; for long experience has ſhewn that all places are not equally healthy, or that the proportion of the number of perſons that die annually, is different for different places. Dr. Halley computed a table of the annual deaths as drawn from the bills of mortality of the city of Breſlaw in Germany, Mr. Smart and Mr. Simpſon from thoſe of London, Dr. Price from thoſe of Northampton, Mr. Kerſſeboom from thoſe of the provinces of Holland and Weſt-Frieſland, and M. Parcieux from the liſts of the French tontines, or long annuities, and all theſe are found to differ from one another. It may not therefore be improper to inſert here a comparative view of the principal tables that have been given of this kind, as below, where the firſt column ſhews the age, and the other columns the number of perſons living at that age, out of 1000 born, or of the age 0, in the firſt line of each column.

TABLE I.

Shewing the Number of Perſons living at all Ages, out of 1000 *that had been born at ſeveral Places, viz.*

Ages.	Vienna.	Berlin.	London.	Norwich.	North-ampton.	Breſlaw.	Branden-burg.	Holy-Croſs.	Holland.	France.	Vaud, Switzer-land.

Theſe tables ſhew that the mortality and chance of life are very various in different places; and that therefore, to obtain a ſufficient accuracy in this buſineſs, it is neceſſary to adapt a table of probabilities or chances of life, to every place for which annuities are to be calculated; or at leaſt one ſet of tables for large towns, and another for country places, as well as for the ſuppoſition of different rates of intereſt.

Several of the foregoing tables, as they commenced with numbers different from one another, are here reduced to the ſame number at the beginning, viz, 1000 perſons, by which means we are enabled by inſpection, at any age, to compare the numbers together, and immediately perceive the relative degrees of vitality at the ſeveral places. The tables are alſo arranged according to the degree of vitality amongſt them; the leaſt, or that at Vienna, firſt; and the reſt in their order, to the higheſt, which is the province of Vaud in Switzerland. The authorities upon which theſe tables depend, are as they here follow. The firſt, taken from Dr. Price's Obſervations on Reverſionary payments, is formed from the bills at Vienna, for 8 years, as given by Mr. Suſmilch, in his *Gottliche* Ordnung; the 2d, for Berlin, from the ſame, as formed from the bills there for 4 years, viz, from 1752 to 1755; the 3d, from Dr. Price, ſhewing the true probabilities of life in London, formed from the bills for ten years, viz, from 1759 to 1768; the 4th, for Norwich, formed by Dr. Price from the bills for 30 years, viz, from 1740 to 1769; the 5th, by the ſame, from the bills for Northampton; the 6th, as deduced by Dr. Halley, from the bills of mortality at Breſlaw; the 7th ſhews the probabilities of life in a country pariſh in Brandenburg, formed from the bills for 50 years, from 1710 to 1759, as given by Mr. Suſmilch; the 8th ſhews the probabilities of life in the pariſh of Holy-Croſs, near Shrewſbury, formed from a regiſter kept by the Rev. Mr. Garſuch, for 20 years, from 1750 to 1770; the 9th, for Holland,

Holland, was formed by M. Kerſſeboom, from the regiſters of certain annuities for lives granted by the government of Holland, which had been kept there for 125 years, in which the ages of the ſeveral annuitants dying during that period had been truly entered; the 10th, for France, were formed by M. Parcieux, from the lifts of the French tontines, or long annuities, and verified by a compariſon with the mortuary regiſters of ſeveral religious houſes for both ſexes; and the 11th, or laſt, for the diſtrict of Vaud in Switzerland, was formed by Dr. Price from the regiſters of 43 pariſhes, given by M. Muret, in the Bern Memoirs for the year 1766.

Now from ſuch lifts as the foregoing, various tables have been formed for the valuation of annuities on ſingle and joint lives, at ſeveral rates of intereſt, in which the value is ſhewn by inſpection. The following are thoſe that are given by Mr. Simpſon, in his Select Exerciſes, as deduced from the London bills of mortality.

TABLE II.

Shewing the Value of an Annuity on One Life, or Number of Years Annuity in the Value, ſuppoſing Money to bear Intereſt at the ſeveral Rates of 3, 4, *and* 5 *per cent.*

Age.	Years value at 3 per cent.	Years value at 4 per cent.	Years value at 5 per cent.	Age.	Years value at 3 per cent.	Years value at 4 per cent.	Years value at 5 per cent.

	70	10·0	9·4	8·9
	75	9·3	8·7	8·3
70	70	9·2	8·6	8·2
	75	8·4	7·9	7·6
75	75	7·6	7·2	6·9

The uſes of theſe tables may be exemplified in the following problems.

Prob. 1. *To find the Probability or Proportion of Chance, that a perſon of a Given Age continues in being a propoſed number of years.*—Thus, ſuppoſe the age be 40, and the number of years propoſed 15; then, to calculate by the table of the probabilities for London, in tab. 1. againſt 40 years ſtands 214, and againſt 55 years, the age to which the perſon muſt arrive, ſtands 120, which ſhews that, of 214 perſons who attain to the age of 40, only 120 of them reach the age of 55, and conſequently 94 die between the ages of 40 and 55: It is evident therefore that the odds for attaining the propoſed age of 55, are as 120 to 94, or as 9 to 7 nearly.

Prob. 2. *To find the Value of an Annuity for a propoſed Life.*—This problem is reſolved from tab. 2, by looking againſt the given age, and under the propoſed rate of intereſt; then the correſponding quantity ſhews the number of years-purchaſe required. For example, if the given age be 36, the rate of intereſt 4 per cent, and the propoſed annuity L 250. Then in the table it appears that the value is 12·1 years purchaſe, or 12·1 times L 250, that is L 3025.

After the ſame manner the anſwer will be found in any other caſe falling within the limits of the table. But as there may ſometimes be occaſion to know the values of lives computed at higher rates of intereſt than thoſe in the table, the two following practical rules are ſubjoined; by which the problem is reſolved independent of tables.

Rule 1. When the given age is not leſs than 45 years, nor greater than 85, ſubtract it from 92; then multiply the remainder by the perpetuity, and divide the product by the ſaid remainder added to $2\frac{1}{2}$ times the perpetuity; ſo ſhall the quotient be the number of years purchaſe required. Where note, that by the *perpetuity* is meant the number of years purchaſe of the fee-ſimple; found by dividing 100 by the rate per cent at which intereſt is reckoned.

Ex. Let the given age be 50 years, and the rate of intereſt 10 per cent. Then ſubtracting 50 from 92, there remains 42; which multiplied by 10 the perpetuity, gives 420; and this divided by 67, the remainder increaſed by $2\frac{1}{2}$ times 10 the perpetuity, quotes 6·3 nearly, for the number of years purchaſe. Therefore, ſuppoſing the annuity to be L 100, its value in preſent money will be L 630.

Rule 2. When the age is between 10 and 45 years; take 8 tenths of what it wants of 45, which divide by the rate per cent increaſed by 1·2; then if the quotient be added to the value of a life of 45 years, found by the preceding rule, there will be obtained the number of years purchaſe in this caſe. For example, let the propoſed age be 20 years, and the rate of intereſt 5 per cent. Here taking 20 from 45, there remains 25; $\frac{8}{10}$ of which is 20; which divided by 6·2, quotes 3·2; and this added to 9·8, the value of a life of 45, found by the former rule, gives 13 for the number of years purchaſe that a life of 20 ought to be valued at.

And the concluſions derived by theſe rules, Mr. Simpſon adds, are ſo near the true values, computed from real obſervations, as ſeldom to differ from them by more than $\frac{1}{10}$ or $\frac{2}{10}$ of one year's purchaſe.

The obſervations here alluded to, are thoſe which are founded on the London bills of mortality. And a ſimilar method of ſolution, accommodated to the Breſlaw obſervations, will be as follows, viz. "Multiply the difference between the given age and 85 years by the perpetuity, and divide the product by 8 tenths of the ſaid difference increaſed by double the perpetuity, for the anſwer." Which, from 8 to 80 years of age, will commonly come within leſs than $\frac{1}{8}$ of a year's purchaſe of the truth.

Prob. 3. *To find the Value of an Annuity for Two Joint Lives, that is, for as long as they both continue in being together.*—In table 3, find the younger age, or that neareſt to it, in column 1, and the higher age in column 2; then againſt this laſt is the number of years purchaſe in the proper column for the intereſt. *Ex.* Suppoſe the two ages be 20 and 35 years; then the value

is 10·9 years purchaſe at 3 per cent.
or 9·8 - - at 4 per cent.
or 8·8 - - at 5 per cent.

Prob. 4. *To find the Value of the Annuity for the* Longeſt *of Two Lives, that is, for as long as* either of them *continues in being.*—In table 4, find the age of the youngeſt life, or the neareſt to it, in col. 1, and the age of the elder in col. 2; then againſt this laſt is the anſwer in the proper column of intereſt.—*Ex.* So, if the two ages be 15 and 40; then the value of the annuity upon the longeſt of two ſuch lives,

is 21·1 years purchaſe at 3 per cent.
or 17·9 - - 4 per cent.
or 15·7 - - 5 per cent.

N B. In the laſt two problems, if the younger age, or the rate of intereſt, be not exactly found in the tables, the neareſt to them may be taken, and then by proportion the value for the true numbers will be nearly found.

Rules and tables for the values of three lives, &c, may alſo be ſeen in Simpſon, and in Baron Maſeres's Annuities, &c. All theſe calculations have been made from tables of the real mortuary regiſters, differing unequally at the ſeveral ages. But rules have alſo been given upon other principles, as by De Moivre, upon the ſuppoſition that the decrements of life are equal at all ages; an aſſumption not much differing from the truth, from 7 to 70 years of age.

Life-Annuities, payable half-yearly, &c.—Theſe are worth more than ſuch as are payable yearly, as computed by the foregoing rules and tables, on the two following accounts: Firſt, that parts of the payments are received ſooner; and 2dly, there is a chance of receiving ſome part or parts of a whole year's payment more than when the payments are only made annually. Mr. Simpſon, in his Select Exerciſes, pa. 283, obſerves, that the value of theſe two advantages put together, will always amount to $\frac{1}{4}$ of a year's purchaſe for half-yearly payments, and to $\frac{3}{8}$ of a year's purchaſe for quarterly payments; and Mr. Maſeres, at page 233 &c of his Annuities, by a very elaborate calculation, finds the former difference to be nearly $\frac{1}{4}$ alſo. But Dr. Price, in an Eſſay in the Philoſ. Tranſ. vol. 66,

pa. 109, ſtates the ſame differences only
at $\frac{2}{75}$ for half-yearly payments,
and $\frac{3}{75}$ for quarterly payments:
And the Doctor then adds ſome algebraical theorems for ſuch calculations.

LIFE-ANNUITIES, *ſecured by Land.*—Theſe differ from other life-annuities only in this, that the annuity is to be paid up to the very day of the death of the age in queſtion, or of the perſon upon whoſe life the annuity is granted. To obtain the more exact value therefore of ſuch an annuity, a ſmall quantity muſt be added to the ſame as computed by the foregoing rules and obſervations, which is different according as the payments are yearly, half-yearly, or quarterly, &c; and are thus ſtated by Dr. Price in his Eſſay quoted above; viz, the addition

is $\frac{y}{2n}$ for annual payments,

or $\frac{b}{4n}$ for half-yearly payments,

or $\frac{q}{8n}$ for quarterly payments:

where n is the complement of the given age, or what it wants of 86 years; and y, b, q are the reſpective values of an annuity *certain* for n years, payable yearly, half-yearly, or quarterly. And, by numeral examples, it is found that the firſt of theſe additional quantities is about $\frac{2}{75}$, the ſecond $\frac{1}{75}$, and the 3d half a tenth of one year's purchaſe.

Complement of LIFE. See COMPLEMENT.

Expectation of LIFE. See EXPECTATION.

Inſurance or Aſſurance on LIVES. See ASSURANCES *on Lives.*

LIGHT, that principle by which objects are made perceptible to our ſenſe of ſeeing; or the ſenſation occaſioned in the mind by the view of luminous objects.

The nature of Light has been a ſubject of ſpeculation from the firſt dawnings of philoſophy. Some of the earlieſt philoſophers doubted whether objects became viſible by means of any thing proceeding from them, or from the eye of the ſpectator. But this opinion was qualified by Empedocles and Plato, who maintained, that viſion was occaſioned by particles continually flying off from the ſurfaces of bodies, which meet with others proceeding from the eye; while the effect was aſcribed by Pythagoras ſolely to the particles proceeding from the external objects, and entering the pupil of the eye. But Ariſtotle defines Light to be the act of a tranſparent body, conſidered as ſuch: and he obſerves that Light is not fire, nor yet any matter radiating from the luminous body, and tranſmitted through the tranſparent one.

The Carteſians have refined conſiderably on this notion; and hold that Light, as it exiſts in the luminous body, is only a power or faculty of exciting in us a very clear and vivid ſenſation; or that it is an inviſible fluid preſent at all times and in all places, but requiring to be ſet in motion, by a body ignited or otherwiſe properly qualified to make objects viſible to us.

Father Malbranche explains the nature of Light from a ſuppoſed analogy between it and ſound.—Thus he ſuppoſes all the parts of a luminous body are in a rapid motion, which, by very quick pulſes, is conſtantly compreſſing the ſubtle matter between the luminous body and the eye, and excites vibrations of preſſion. As theſe vibrations are greater, the body appears more luminous; and as they are quicker or ſlower, the body is of this or that colour.

But the Newtonians maintain, that Light is not a fluid *per ſe*, but conſiſts of a great number of very ſmall particles, thrown off from the luminous body by a repulſive power with an immenſe velocity, and in all directions. And theſe particles, it is alſo held, are emitted in right lines: which rectilinear motion they preſerve till they are turned out of their path by ſome of the following cauſes, viz, by the attraction of ſome other body near which they paſs, which is called *inflection*; or by paſſing obliquely through a medium of different denſity, which is called *refraction*; or by being turned aſide by the oppoſition of ſome intervening body, which is called *reflection*; or, laſtly, by being totally ſtopped by ſome ſubſtance into which they penetrate, and which is called their *extinction*. A ſucceſſion of theſe particles following one another, in an exact ſtraight line, is called a *ray of Light*; and this ray, in whatever manner its direction may be changed, whether by refraction, reflection, or inflection, always preſerves a rectilinear courſe till it be again changed: neither is it poſſible to make it move in the arch of a circle, ellipſis, or other curve. For the above properties of the rays of Light, ſee the ſeveral words, REFRACTION, REFLECTION, &c.

The *velocity* of the particles and rays of Light is truly aſtoniſhing, amounting to near 2 hundred thouſand miles in a ſecond of time, which is near a million times greater than the velocity of a cannon-ball. And this amazing motion of Light has been manifeſted in various ways, and firſt, from the eclipſes of Jupiter's ſatellites. It was firſt obſerved by Roemer, that the eclipſes of thoſe ſatellites happen ſometimes ſooner, and ſometimes later, than the times given by the tables of them; and that the obſervation was before or after the computed time, according as the earth was nearer to, or farther from Jupiter, than the mean diſtance. Hence Roemer and Caſſini both concluded that this circumſtance depended on the diſtance of Jupiter from the earth; and that, to account for it, they muſt ſuppoſe that the Light was about 14 minutes in croſſing the earth's orbit. This concluſion however was afterward abandoned and attacked by Caſſini himſelf. But Roemer's opinion found an able advocate in Dr. Halley; who removed Caſſini's difficulty, and left Roemer's concluſion in its full force. Yet, in a memoir preſented to the Academy in 1707, M. Maraldi endeavoured to ſtrengthen Caſſini's arguments; when Roemer's doctrine found a new defender in Mr. Pound. See Philoſ. Tranſ. number 136, alſo Abridg. vol. 1, pa. 409 and 422, and Groves, Phyſ. Elem. number 2636. It has ſince been found, by repeated experiments, that when the earth is exactly between Jupiter and the ſun, his ſatellites are ſeen eclipſed about 8½ minutes *ſooner* than they could be according to the tables; but when the earth is nearly in the oppoſite point of its orbit, theſe eclipſes happen about 8¼ minutes *later* than the tables predict them. Hence

then it is certain that the motion of Light is not inſtantaneous, but that it takes up about 16½ minutes of time to paſs over a ſpace equal to the diameter of the earth's orbit, which is at leaſt 190 millions of miles in length, or at the rate of near 200,000 miles per ſecond, as above-mentioned. Hence therefore Light takes up about 8¼ minutes in paſſing from the ſun to the earth; ſo that, if he ſhould be annihilated, we would ſee him for 8¼ minutes after that event ſhould happen; and if he were again created, we ſhould not ſee him till 8¼ minutes afterwards. Hence alſo it is eaſy to know the time in which Light travels to the earth, from the moon, or any of the other planets, or even from the fixed ſtars when their diſtances ſhall be known; theſe diſtances however are ſo immenſely great, that from the neareſt of them, ſuppoſed to be Sirius, the dog-ſtar, Light takes up many years to travel to the earth: and it is even ſuſpected that there are many ſtars whoſe Light have not yet arrived at us ſince their creation. And this, by-the-bye, may perhaps ſometimes account for the appearance of new ſtars in the heavens.

It may be juſt obſerved that Galileo firſt conceived the notion of meaſuring the velocity of Light; and a deſcription of his contrivance for this purpoſe, is in his Treatiſe on Mechanics, pa. 39. He had two men with Lights covered; the one was to obſerve when the other uncovered his Light, and to exhibit his own the moment he perceived it. This rude experiment was tried at the diſtance of a mile, but without ſucceſs, as may naturally be imagined: and the members of the Academy Del Cimento repeated the experiment, and placed their obſervers, to as little purpoſe, at the diſtance of 2 miles.

But our excellent aſtronomer, Dr. Bradley, afterwards found nearly the ſame velocity of Light as Roemer, from his accurate obſervations, and moſt ingenious theory, to account for ſome apparent motions in the fixed ſtars; for an account of which, ſee ABERRATION of Light. By a long ſeries of theſe obſervations, he found the difference between the true and apparent place of ſeveral fixed ſtars, for different times of the year; which difference could no otherwiſe be accounted for, than from the progreſſive motion of the rays of Light. From the mean quantity of this difference he ingeniouſly found, that the ratio of the velocity of Light to the velocity of the earth in its orbit, was as 10313 to 1, or that Light moves 10313 times faſter than the earth moves in its orbit about the ſun; and as this latter motion is at the rate of 18½½ miles per ſecond nearly, it follows that the former, or the velocity of Light, is at the rate of about 195000 miles in a ſecond; a motion according to which it will require juſt 8′ 7″ to move from the ſun to the earth; or about 95 millions of miles.

It was alſo inferred, from the foregoing principles, that Light proceeds with the ſame velocity from all the ſtars. And hence it follows, if we ſuppoſe that all the ſtars are not equally diſtant from us, as many arguments prove, that the motion of Light, all the way it paſſes through the immenſe ſpace above our atmoſphere, is equable or uniform. And ſince the different methods of determining the velocity of Light thus agree in the reſult, it is reaſonable to conclude that, in the ſame medium, Light is propagated with the ſame velocity after it has been reflected, as before.

For an account of Mr. Melville's hypotheſis of the different velocities of differently coloured rays, ſee COLOUR.

To the doctrine concerning the materiality of Light, and its amazing velocity, ſeveral objections have been made; of which the moſt conſiderable is, That as rays of Light are continually paſſing in different directions from every viſible point, they muſt neceſſarily interfere with each other in ſuch a manner, as entirely to confound all diſtinct perception of objects, if not quite to deſtroy the whole ſenſe of ſeeing: not to mention the continual waſte of ſubſtance which a conſtant emiſſion of particles muſt occaſion in the luminous body, and thereby ſince the creation muſt have greatly diminiſhed the matter in the ſun and ſtars, as well as increaſed the bulk of the earth and planets by the vaſt quantity of particles of Light abſorbed by them in ſo long a period of time.

But it has been replied, that if Light were not a body, but conſiſted in mere preſſion or pulſion, it could never be propagated in right lines, but would be continually inflected ad umbram. Thus Sir I. Newton: "A preſſure on a fluid medium, i. e. a motion propagated by ſuch a medium, beyond any obſtacle, which impedes any part of its motion, cannot be propagated in right lines, but will be always inflecting and diffuſing itſelf every way, to the quieſcent medium beyond that obſtacle. The power of gravity tends downwards; but the preſſure of water ariſing from it tends every way with an equable force, and is propagated with equal eaſe and equal ſtrength, in curves, as in ſtrait lines. Waves, on the ſurface of the water, gliding by the extremes of any very large obſtacle, inflect and dilate themſelves, ſtill diffuſing gradually into the quieſcent water beyond that obſtacle. The waves, pulſes, or vibrations of the air, wherein ſound conſiſts, are manifeſtly inflected, though not ſo conſiderably as the waves of water; and ſounds are propagated with equal eaſe, through crooked tubes, and through ſtrait lines; but Light was never known to move in any curve, nor to inflect itſelf ad umbram."

It muſt be acknowledged, however, that many philoſophers, both Engliſh and Foreigners, have recurred to the opinion, that Light conſiſts of vibrations propagated from the luminous body, through a ſubtle etherial medium.

The ingenious Dr. Franklin, in a letter dated April 23, 1752, expreſſes his diſſatisfaction with the doctrine, that Light conſiſts of particles of matter continually driven off from the ſun's ſurface, with ſo enormous a ſwiftneſs. "Muſt not, ſays he, the ſmalleſt portion conceivable, have, with ſuch a motion, a force exceeding that of a 24 pounder diſcharged from a cannon? Muſt not the ſun diminiſh exceedingly by ſuch a waſte of matter; and the planets, inſtead of drawing nearer to him, as ſome have feared, recede to greater diſtances through the leſſened attraction? Yet theſe particles, with this amazing motion, will not drive before them, or remove, the leaſt and ſlighteſt duſt they meet with; and the ſun appears to continue of his ancient dimenſions, and his attendants move in their ancient orbits." He therefore conjectures that all the phenomena of

Light

Light may be more properly ſolved, by ſuppoſing all ſpace filled with a ſubtle elaſtic fluid, which is not viſible when at reſt, but which, by its vibrations, affects that fine ſenſe in the eye, as thoſe of the air affect the groſſer organs of the ear; and even that different degrees of the vibration of this medium may cauſe the appearances of different colours. Franklin's Exper. and Obſerv. 1769, pa. 264.

The celebrated Euler has alſo maintained the ſame hypotheſis, in his Theoria Lucis & Colorum. In the ſummary of his arguments againſt the common opinion, recited in Acad. Berl. 1752, pa. 271, beſides the objections above-mentioned, he doubts the poſſibility, that particles of matter, moving with the amazing velocity of Light, ſhould penetrate tranſparent ſubſtances with ſo much eaſe. In whatever manner they are tranſmitted, thoſe bodies muſt have pores, diſpoſed in right lines, and in all poſſible directions, to ſerve as canals for the paſſage of the rays: but ſuch a ſtructure muſt take away all ſolid matter from thoſe bodies, and all coherence among their parts, if they do contain any ſolid matter.

Doctor Horſley, now Bp. of Rocheſter, has taken conſiderable pains to obviate the difficulties ſtarted by Dr. Franklin. Suppoſing that the diameter of each particle of Light does not exceed one millionth of one millionth of an inch, and that the denſity of each particle is even three times that of iron, that the Light of the ſun reaches the earth in 7′, at the diſtance of 22919 of the earth's ſemidiameters, he calculates that the momentum or force of motion in each particle of Light coming from the ſun, is leſs than that in an iron ball of a quarter of an inch diameter, moving at the rate of leſs than an inch in 12 thouſand millions of millions of years. And hence he concludes, that a particle of matter, which probably is larger than any particle of Light, moving with the velocity of Light, has a force of motion, which, inſtead of exceeding the force of a 24 pounder diſcharged from a cannon, is almoſt infinitely leſs than that of the ſmalleſt ſhot diſcharged from a pocket piſtol, or leſs than any that art can create. He alſo thinks it poſſible, that Light may be produced by a continual emiſſion of matter from the ſun, without any ſuch waſte of his ſubſtance as ſhould ſenſibly contract his dimenſions, or alter the motions of the planets, within any moderate length of time. In proof of this, he obſerves that, for the production of any of the phenomena of Light, it is not neceſſary that the emanation from the ſun ſhould be continual, in a ſtrict mathematical ſenſe, or without any interval; and likewiſe that part of the Light which iſſues from the ſun, is continually returned to him by reflection from the planets, as well as other Light from the ſuns of other ſyſtems. He proceeds, by calculation, to ſhew that in 385,130,000 years, the ſun would loſe but the 13232d part of his matter, and conſequently of the gravitation towards him, at any given diſtance; which is an alteration much too ſmall to diſcover itſelf in the motion of the earth, or of any of the planets. He farther computes that the greateſt ſtroke which the retina of a common eye ſuſtains, when turned directly to the ſun in a bright day, does not exceed that which would be given by an iron ſhot, a quarter of an inch diameter, and moving only at the rate of $16\frac{1}{6}$ inches in a year; whereas the ordinary ſtroke is leſs than the 2084th part of this. See Philoſ. Tranſ. vol. 60 and 61.

In anſwer to the difficulty reſpecting the non-interference of the particles of Light with each other, Mr. Melville obſerves (Edinb. Eſſ. vol. 2), there is probably no phyſical point in the viſible horizon, that does not ſend rays to every other point, unleſs where opaque bodies interpoſe. Light, in its paſſage from one ſyſtem to another, often paſſes through torrents of Light iſſuing from other ſuns and ſyſtems, without ever interfering, or being diverted from its courſe, either by it, or by the particles of that elaſtic medium, which it has been ſuppoſed by ſome is diffuſed through all the mundane ſpace. To account for this fact, he ſuppoſes that the particles of Light are incomparably rare, even when they are the moſt denſe, or that their diameters are incomparably leſs than their diſtance from one another: which obviates the objection urged by Euler and others againſt the materiality of Light, from its influence in diſturbing the freedom and perpetuity of the celeſtial motions. Boſcovich and ſome others ſolve the difficulty concerning the non-interference of the particles of Light, by ſuppoſing that each particle is endued with an inſuperable impulſive force; but in this caſe, their ſpheres of impulſion would be more likely to interfere, and on that account they be more liable to diſturb one another.

M. Canton ſhews (Philoſ. Tranſ. vol. 58, p. 344), that the difficulty of the interference will vaniſh, if a very ſmall portion of time be allowed between the emiſſion of every particle and the next that follows in the ſame direction. Suppoſe, for inſtance, that a lucid point in the ſun's ſurface emits 150 particles in a ſecond of time, which, he obſerves, will be more than ſufficient to give continual Light to the eye, without the leaſt appearance of intermiſſion; yet ſtill the particles of ſuch a ray, on account of their great velocity, will be more than 1000 miles behind each other, a ſpace ſufficient to allow others to paſs in all directions without any perceptible interruption. And if we adopt the concluſions drawn from the experiments on the duration of the ſenſations excited by Light, by the chevalier D'Arcy, in the Acad. Scienc. 1765, who ſtates it at the 7th part of a ſecond, an interval of more than 20,000 miles may be admitted between every two ſucceſſive particles.

The doctrine of the materiality of Light is farther confirmed by thoſe experiments, which ſhew, that the colour and inward texture of ſome bodies are changed by being expoſed to the Light.

Of the Momentum, or Force, of the Particles of Light. Some writers have attempted to prove the materiality of Light, by determining the momentum of their component particles, or by ſhewing that they have a force ſo as, by their impulſe, to give motion to light bodies. M. Homberg, Ac. Par. 1708, Hiſt. pa. 25, imagined, that he could not only diſperſe pieces of amianthus, and other light ſubſtances, by the impulſe of the ſolar rays, but alſo that by throwing them upon the end of a kind of lever, connected with the ſpring of a watch, he could make it move ſenſibly quicker; from which, and other experiments, he inferred the weight of the particles of Light. And Hartſoecker made preten-

ſions of the ſame nature. But M. Du Fay and M. Mairan made other experiments of a more accurate kind, without the effects which the former had imagined, and which even proved that the effects mentioned by them were owing to currents of heated air produced by the burning glaſſes uſed in their experiments, or ſome other cauſes which they had overlooked.

However, Dr. Prieſtley informs us, that Mr. Michell endeavoured to aſcertain the momentum of Light with ſtill greater accuracy, and that his endeavours were not altogether without ſucceſs. Having found that the inſtrument he uſed, acquired, from the impulſe of the rays of light, a velocity of an inch in a ſecond of time, he inferred that the quantity of matter contained in the rays falling upon the inſtrument in that time, amounted to no more than the 12 hundred millionth part of a grain. In the experiment, the Light was collected from a ſurface of about 3 ſquare feet; and as this ſurface reflected only about the half of what fell upon it, the quantity of matter contained in the ſolar rays, incident upon a ſquare foot and a half of ſurface, in a ſecond of time, ought to be no more than the 12 hundred millionth part of a grain, or upon one ſquare foot only, the 18 hundred millionth part of a grain. But as the denſity of the rays of Light at the ſurface of the ſun, is 45000 times greater than at the earth, there ought to iſſue from a ſquare foot of the ſun's ſurface, in one ſecond of time, the 40 thouſandth part of a grain of matter; that is, a little more than 2 grains a day, or about 4,752,000 grains, which is about 670 pounds avoirdupois, in 6000 years, the time ſince the creation; a quantity which would have ſhortened the ſun's ſemidiameter by no more than about 10 feet, if it be ſuppoſed of no greater denſity than water only.

The *Expanſion* or *Extenſion* of any portion of Light, is inconceivable. Dr. Hook ſhews that it is as unlimited as the univerſe; which he proves from the immenſe diſtance of many of the fixed ſtars, which only become viſible to the eye by the beſt teleſcopes. Nor, adds he, are they only the great bodies of the ſun or ſtars that are thus liable to diſperſe their Light through the vaſt expanſe of the univerſe, but the ſmalleſt ſpark of a lucid body muſt do the ſame, even the ſmalleſt globule ſtruck from a ſteel by a flint.

The *Intenſity* of different Lights, or of the ſame Light in different circumſtances, affords a curious ſubject of ſpeculation. M. Bouguer, Traité de Optique, found that when one Light is from 60 to 80 times leſs than another, its preſence or abſence will not be perceived by an ordinary eye; that the moon's Light, when ſhe is 19° 16′ high above the horizon, is but about ⅓ of her Light at 66° 11′ high; and when one limb juſt touched the horizon, her Light was but the 2000th part of her Light at 66° 11′ high; and that hence Light is diminiſhed in the proportion of 3 to 1 by traverſing 7469 toiſes of denſe air. He found alſo, that the centre of the ſun's diſc is conſiderably more luminous than the edges of it; whereas both the primary and ſecondary planets are more luminous at their edges than near their centres: That, farther, the Light of the ſun is about 300,000 times greater than that of the moon; and therefore it is no wonder that philoſophers have had ſo little ſucceſs in their attempts to collect the Light of the moon with burning-glaſſes; for, ſhould one of the largeſt of them even increaſe the Light 1000 times, it will ſtill leave the Light of the moon in the focus of the glaſs, 300 times leſs than the intenſity of the common Light of the ſun.

Dr. Smith, in his Optics, vol. 1, pa. 29, thought he had proved that the Light of the full moon would be only the 90,900th part of the full day Light, if no rays were loſt at the moon. But Mr. Robins, in his Tracts, vol. 2, pa. 225, ſhews that this is too great by one half. And Mr. Michell, by a more eaſy and accurate mode of computation, found that the denſity of the ſun's Light on the ſurface of the moon is but the 45,000th part of the denſity at the ſun; and that therefore, as the moon is nearly of the ſame apparent magnitude as the ſun, if ſhe reflected to us all the Light received on her ſurface, it would be only the 45,000th part of our day Light, or that which we receive from the ſun. Admitting therefore, with M. Bouguer, that the moon Light is only the 300,000th part of the day or ſun's Light, Mr. Michell concludes that the moon reflects no more than between the 6th and 7th part of what ſhe receives.

Dr. Graveſande ſays, a lucid body is that which emits or gives fire a motion in right lines, and makes the difference between Light and heat to conſiſt in this, that to produce the former, the fiery particles muſt enter the eye in a rectilinear motion, which is not required in the latter: on the contrary, an irregular motion ſeems more proper for it, as appears from the rays coming directly from the ſun to the tops of mountains, which have not near that effect with thoſe in the valley, agitated with an irregular motion, by ſeveral reflections.

Sir I. Newton obſerves, that bodies and Light act mutually on one another; bodies on Light, in emitting, reflecting, refracting, and inflecting it; and Light on bodies, by heating them, and putting their parts into a vibrating motion, in which heat principally conſiſts. For all fixed bodies, he obſerves, when heated beyond a certain degree, do emit Light, and ſhine; which ſhining &c appears to be owing to the vibrating motion of their parts; and all bodies, abounding in earthy and ſulphureous particles, if ſufficiently agitated, emit Light, which way ſoever that agitation be effected. Thus, ſea water ſhines in a ſtorm; quickſilver, when ſhaken in vacuo; cats or horſes, when rubbed in the dark; and wood, fiſh, and fleſh, when putrefied.

Light proceeding from putreſcent animal and vegetable ſubſtances, as well as from glow-worms, is mentioned by Ariſtotle. And Bartholin mentions four kinds of luminous inſects, two of which have wings: but in hot climates it is ſaid they are found in much greater numbers, and of different ſpecies. Columna obſerves, that their Light is not extinguiſhed immediately on the death of the animal. The firſt diſtinct account that occurs of Light proceeding from putreſcent animal fleſh, is that which is given by Fabricius ab Aquapendente in 1592, de Viſione &c, pa. 45. And Bartholin gives an account of a ſimilar appearance, which happened at Montpelier in 1641, in his treatiſe De Luce Animalium.

Mr. Boyle ſpeaks of a piece of *ſhining* rotten wood, which was extinguiſhed in vacuo; but upon re-admitting the air, it revived again, and ſhone as before; though

though he could not perceive that it was increaſed in condenſed air. But in Birch's Hiſtory of the Royal Soc. vol. 2, pa. 254, there is an account of the Light of a ſhining fiſh, which was rendered more vivid by putting the fiſh into a condenſing engine. The fiſh called Whitings were thoſe commonly uſed by Mr. Boyle in his experiments: though in a diſcourſe read before the R. Soc. in 1681, it was aſſerted that, of all fiſhy ſubſtances, the eggs of lobſters, after they had been boiled, ſhone the brighteſt. Birch's Hiſt. vol. 2, pa. 70. In 1672 Mr. Boyle accidentally obſerved Light iſſuing from fleſh meat; and, among other remarks on this ſubject, he obſerves that extreme cold extinguiſhes the Light of ſhining wood; probably becauſe extreme cold checks the putrefaction, which is the cauſe of the Light. The ſhell fiſh called Pholas, is remarkable for its luminous quality. The *luminouſneſs of the Sea* has been alſo a ſubject of frequent obſervation. See *Ignis fatuus*, *Phoſphorus*, and *Putrefaction*, &c.

Mr. Hawkſbee, and many writers on the ſubject of electricity ſince his time, have produced a great variety of inſtances of the artificial production of Light, by the attrition of bodies naturally not luminous; as of amber rubbed on woollen cloth in vacuo; of glaſs on woollen, of glaſs on glaſs, of oyſter ſhells on woollen, and of woollen on woollen, all in vacuo. On the ſeveral experiments of this kind, he makes theſe following reflections: that different ſorts of bodies afford Light of various kinds, different both in colour and in force; that the effects of an attrition are various, according to the different preparations and treatment of the bodies that are to endure it; and that bodies which have yielded a particular Light, may be brought by friction to yield no more of that Light.

M. Bernoulli found by experiment, that mercury amalgamated with tin, and rubbed on glaſs, produced a conſiderable Light in the air; that gold rubbed on glaſs, exhibited the ſame in a greater degree; but that the moſt exquiſite Light of all was produced by the attrition of a diamond, this being equally vivid with that of a burning coal briſkly agitated with the bellows. See ELECTRICITY, &c.

Of the Attraction of Light. That the particles of Light are attracted by thoſe of other bodies, is evident from numerous experiments. This phenomenon was obſerved by Sir I. Newton, who found, by repeated trials, that the rays of Light, in their paſſage near the edges of bodies, are diverted out of the right lines, and always inflected or bent towards thoſe bodies, whether they be opaque or tranſparent, as pieces of metals, the edges of knives, broken glaſſes, &c. See INFLECTION and RAYS. The curious obſervations that had been made on this ſubject by Dr. Hook and Grimaldi, led Sir I. Newton to repeat and diverſify their experiments, and to purſue them much farther than they had done. For a particular account of his experiment and obſervations, ſee his treatiſe on Optics, pa. 293 &c.

This action of bodies on Light is found to exert itſelf at a ſenſible diſtance, though it always increaſes as the diſtance is diminiſhed; as appears very ſenſibly in the paſſage of a ray between the edges of two thin planes at different apertures; which is attended with this peculiar circumſtance, that the attraction of one edge is increaſed as the other is brought nearer it. The rays of Light, in their paſſage out of glaſs into a vacuum, are not only inflected towards the glaſs, but if they fall too obliquely, they will revert back again to the glaſs, and be totally reflected. Now the cauſe of this reflection cannot be attributed to any reſiſtance of the vacuum, but muſt be entirely owing to ſome force or power in the glaſs, which attracts or draws back the rays as they were paſſing into the vacuum. And this appears farther from hence, that if you wet the back ſurface of the glaſs with water, oil, honey, or a ſolution of quickſilver, then the rays which would otherwiſe have been reflected, will pervade and paſs through that liquor; which ſhews that the rays are not reflected till they come to that back ſurface of the glaſs, nor even till they begin to go out of it; for if, at their going out, they fall into any of the aforeſaid mediums, they will not then be reflected, but will perſiſt in their former courſe, the attraction of the glaſs being in this caſe counterbalanced by that of the liquor.

M. Maraldi proſecuted experiments ſimilar to thoſe of Sir I. Newton on inflected Light. And his obſervations chiefly reſpect the inflection of Light towards other bodies, by which their ſhadows are partially illuminated. Acad. Paris 1723, Mem. p. 159. See alſo Prieſtley's Hiſt. pa. 521 &c.

M. Mairan, without attempting the diſcovery of new facts, endeavoured to explain the old ones, by the hypotheſis of an atmoſphere ſurrounding all bodies; and conſequently two reflections and refractions of Light that impinges upon them, one at the ſurface of the atmoſphere, and the other at the ſurface of the body itſelf. This atmoſphere he ſuppoſed to be of a variable denſity and refractive power, like the air.

M. Du Tour ſucceeded Mairan, and imagined that he could account for all the phenomena by the help of an atmoſphere of an uniform denſity, but of a leſs refractive power than the air ſurrounding all bodies. Du Tour alſo varied the Newtonian experiments, and diſcovered more than three fringes in the colours produced by the inflection of light. He farther concludes that the refracting atmoſpheres, ſurrounding all kinds of bodies, are of the ſame ſize; for when he uſed a great variety of ſubſtances, and of different ſizes too, he always found coloured ſtreaks of the ſame dimenſions. He alſo obſerves, that his hypotheſis contradicts an obſervation of Sir I. Newton, viz, that thoſe rays are the moſt inflected which paſs the neareſt to any body. Mem. de Math. & de Phyſ. vol. 5, pa. 650, or Prieſtley's Hiſt. pa. 531.

M. Le Cat found that objects ſometimes appear magnified by means of the inflection of Light. Looking at a diſtant ſteeple, when a wire, of a leſs diameter than the pupil of his eye, was held pretty near to it, and drawing it ſeveral times between that object and his eye, he was ſurpriſed to find that every time the wire paſſed before his eye, the ſteeple ſeemed to change its place, and ſome hills beyond the ſteeple ſeemed to have the ſame motion, juſt as if a lens had been drawn between them and his eye. This diſcovery led him to ſeveral others depending on the inflection of the rays of Light. Thus, he magnified ſmall objects, as the head of a pin, by viewing them through a ſmall hole in a card; ſo that the rays which formed the image muſt neceſſarily

neceſſarily paſs ſo near the circumference of the hole, as to be attracted by it. He exhibited alſo other appearances of a ſimilar nature. Traité des Sens, pa. 299. Prieſtley, ubi ſupra, pa. 537.

Reflection and Refraction of Light. From the mutual attraction between the particles of Light and other bodies, ariſe two other grand phenomena, beſides the inflection of Light, which are called the reflection and refraction of Light. It is well known that the determination of bodies in motion, eſpecially elaſtic ones, is changed by the interpoſition of other bodies in their way: thus alſo Light, impinging on the ſurfaces of bodies, ſhould be turned out of its courſe, and beaten back or reflected, ſo as, like other ſtriking bodies, to make the angle of its reflection equal to the angle of incidence. This, it is found by experience, Light does; and yet the cauſe of this effect is different from that juſt now aſſigned: for the rays of Light are not reflected by ſtriking on the very parts of the reflecting bodies, but by ſome power equally diffuſed over the whole ſurface of the body, by which it acts on the Light, either attracting or repelling it, without contact: by which ſame power, in other circumſtances, the rays are refracted; and by which alſo the rays are firſt emitted from the luminous body; as Newton abundantly proves by a great variety of arguments. See REFLECTION and REFRACTION.

That great author puts it paſt doubt, that all thoſe rays which are reflected, do not really touch the body, though they approach it infinitely near; and that thoſe which ſtrike on the parts of ſolid bodies, adhere to them, and are as it were extinguiſhed and loſt. Since the reflection of the rays is aſcribed to the action of the whole ſurface of the body without contact, if it be aſked, how it happens that all the rays are not reflected from every ſurface; but that, while ſome are reflected, others paſs through, and are refracted? the anſwer given by Newton is as follows:—Every ray of Light, in its paſſage through any refracting ſurface, is put into a certain tranſient conſtitution or ſtate, which in the progreſs of the ray returns at equal intervals, and diſpoſes the ray at every return to be eaſily tranſmitted through the next refracting ſurface, and between the returns to be eaſily reflected by it: which alteration of reflection and tranſmiſſion it appears is propagated from every ſurface, and to all diſtances. What kind of action or diſpoſition this is, and whether it conſiſts in a circulating or vibrating motion of the ray, or the medium, or ſomething elſe, he does not enquire; but allows thoſe who are fond of hypotheſes to ſuppoſe, that the rays of Light, by impinging on any reflecting or refracting ſurface, excite vibrations in the reflecting or refracting medium, and by that means agitate the ſolid parts of the body. Theſe vibrations, thus produced in the medium, move faſter than the rays, ſo as to overtake them; and when any ray is in that part of the vibration which conſpires with its motion, its velocity is increaſed, and ſo it eaſily breaks through a refracting ſurface; but when it is in a contrary part of the vibration, which impedes its motion, it is eaſily reflected; and thus every ray is ſucceſſively diſpoſed to be eaſily reflected or tranſmitted by every vibration which meets it. Theſe returns in the diſpoſition of any ray to be reflected, he calls *fits of eaſy reflection*; and the returns in the diſpoſition to be tranſmitted, he calls *fits of eaſy tranſmiſſion*; alſo the ſpace between the returns, *the interval of the fits*. Hence then the reaſon why the ſurfaces of all thick tranſparent bodies reflect part of the Light incident upon them, and refract the reſt, is that ſome rays at their incidence are in fits of eaſy reflection, and others of eaſy tranſmiſſion. For *the properties of reflected Light*, ſee REFLECTION, MIRROR, &c.

Again, a ray of Light, paſſing out of one medium into another of different denſity, and in its paſſage making an oblique angle with the ſurface that ſeparates the mediums, will be refracted, or turned out of its direction; becauſe the rays are more ſtrongly attracted by a denſer than by a rarer medium. That theſe rays are not refracted by ſtriking on the ſolid parts of bodies, but that this is effected without a real contact, and by the ſame force by which they are emitted and reflected, only exerting itſelf differently in different circumſtances, is proved in a great meaſure by the ſame arguments by which it is demonſtrated that reflection is performed without contact. See REFRACTION, LENS, COLOUR, VISION, &c.

LIGHTNING, a large bright flame, ſhooting ſwiftly through the atmoſphere, of momentary or very ſhort duration, and commonly attended with thunder.

Some philoſophers accounted for this awful natural phenomenon in this manner, viz, that an inflammable ſubſtance is formed of the particles of ſulphur, nitre, and other combuſtible matter, which are exhaled from the earth, and carried into the higher regions of the atmoſphere, and that by the colliſion of two clouds, or otherwiſe, this ſubſtance takes fire, and darts out into a train of Light, larger or ſmaller according to the ſtrength and quantity of the materials. And others have explained the phenomenon of Lightning by the fermentation of ſulphureous ſubſtances with nitrous acids. See THUNDER.

But it is now univerſally allowed, that Lightning is really an electrical exploſion or phenomenon. Philoſophers had not proceeded far in their experiments and enquiries on this ſubject, before they perceived the obvious analogy between Lightning and electricity, and they produced many arguments to evince their ſimilarity. But the method of proving this hypotheſis beyond a doubt, was firſt propoſed by Dr. Franklin, who, about the cloſe of the year 1749, conceived the practicability of drawing Lightning down from the clouds. Various circumſtances of reſemblance between Lightning and electricity were remarked by this ingenious philoſopher, and have been abundantly confirmed by later diſcoveries, ſuch as the following: Flaſhes of Lightning are uſually ſeen crooked and waving in the air; ſo the electric ſpark drawn from an irregular body at ſome diſtance, and when it is drawn by an irregular body, or through a ſpace in which the beſt conductors are diſpoſed in an irregular manner, always exhibits the ſame appearance: Lightning ſtrikes the higheſt and moſt pointed objects in its courſe, in preference to others, as hills, trees, ſpires, maſts of ſhips, &c; ſo all pointed conductors receive and throw off the electric fluid more readily than thoſe that are terminated by flat ſurfaces: Lightning is obſerved to take and follow the readieſt and beſt conductor; and the ſame is the caſe with electricity in the diſcharge of the Leyden

phial; from whence the doctor infers, that in a thunder-ſtorm, it would be ſafer to have one's cloaths wet than dry: Lightning burns, diſſolves metals, rends ſome bodies, ſometimes ſtrikes perſons blind, deſtroys animal life, deprives magnets of their virtue, or reverſes their poles; and all theſe are well-known properties of electricity.

But Lightning alſo gives polarity to the magnetic needle, as well as to all bodies that have any thing of iron in them, as bricks &c; and by obſerving afterwards which way the magnetic poles of theſe bodies lie, it may thence be known in what direction the ſtroke paſſed. Perſons are ſometimes killed by Lightning, without exhibiting any viſible marks of injury; and in this caſe Sig. Beccaria ſuppoſes that the Lightning does not really touch them, but only produces a ſudden vacuum near them, and the air ruſhing violently out of their lungs to ſupply it, they cannot recover their breath again: and in proof of this opinion he alleges, that the lungs of ſuch perſons are found flaccid; whereas theſe are found inflated when the perſons are really killed by the electric ſhock. Though this hypotheſis is controverted by Dr. Prieſtley.

To demonſtrate however, by actual experiment, the identity of the electric fluid with the matter of Lightning, Dr. Franklin contrived to bring Lightning from the heavens, by means of a paper kite, properly fitted up for the purpoſe, with a long fine wire ſtring, and called an electrical kite, which he raiſed when a thunder-ſtorm was perceived to be coming on: and with the electricity thus obtained, he charged phials, kindled ſpirits, and performed all other ſuch electrical experiments as are uſually exhibited by an excited glaſs globe or cylinder. This happened in June 1752, a month after the electricians in France, in purſuance of the method which he had before propoſed, had verified the ſame theory, but without any knowledge of what they had done. The moſt active of theſe were Meſſrs. Dalibard and Delor, followed by M. Mazeas and M. Monnier.

In April and June 1753, Dr. Franklin diſcovered that the air is ſometimes electrified negatively, as well as ſometimes poſitively; and he even found that the clouds would change from poſitive to negative electricity ſeveral times in the courſe of one thunder-guſt. This curious and important diſcovery he ſoon perceived was capable of being applied to practical uſe in life, and in conſequence propoſed a method, which he ſoon accompliſhed, of ſecuring buildings from being damaged by Lightning, by means of CONDUCTORS. See the word.

Nor had the Engliſh philoſophers been inattentive to this ſubject: but, for want of proper opportunities of trying the neceſſary experiments, and from ſome other unfavourable circumſtances, they had failed of ſucceſs. Mr. Canton, however, ſucceeded in July 1752; and in the following month Dr. Bevis and Mr. Wilſon obſerved near the ſame appearances as Mr. Canton had done before. By a number of experiments Mr. Canton alſo ſoon after obſerved that ſome clouds were in a poſitive, while ſome were in a negative ſtate of electricity; and that the electricity of his conductor would ſometimes change, from one ſtate to the other, five or ſix times in leſs than half an hour.

But Sig. Beccaria diſcovered this variable ſtate of thunder clouds, before he knew that it had been obſerved by Dr. Franklin or any other perſon; and he has given a very exact and particular account of the external appearances of theſe clouds. From the obſervations of his apparatus within doors, and of the Lightning abroad, he inferred, that the quantity of electric matter in a common thunder ſtorm, is inconceivably great, conſidering how many pointed bodies, as ſpires, trees, &c, are continually drawing it off, and what a prodigious quantity is repeatedly diſcharged to or from the earth. This matter is in ſuch abundance, that he thinks it impoſſible for any cloud or number of clouds to contain it all, ſo as either to receive or diſcharge it. He obſerves alſo, that during the progreſs and increaſe of the ſtorm, though the lightning frequently ſtruck to the earth, the ſame clouds were the next moment ready to make a ſtill greater diſcharge, and his apparatus continued to be as much affected as ever; ſo that the clouds muſt have received at one part, in the ſame moment when a diſcharge was made from them in another. And from the whole he concludes, that the clouds ſerve as conductors to convey the electric fluid from thoſe parts of the earth that are overloaded with it, to thoſe that are exhauſted of it. The ſame cauſe by which a cloud is firſt raiſed, from vapours diſperſed in the atmoſphere, draws to it thoſe that are already formed, and ſtill continues to form new ones, till the whole collected maſs extends ſo far as to reach a part of the earth where there is a deficiency of the electric fluid, and where the electric matter will diſcharge itſelf on the earth. A channel of communication being thus formed, a freſh ſupply of electric matter is raiſed from the overloaded part, which continues to be conveyed by the medium of the clouds, till the equilibrium of the fluid is reſtored between the two places of the earth. Sig. Beccaria obſerves, that a wind always blows from the place from which the thunder-cloud proceeds; and it is plain that the ſudden accumulation of ſuch a prodigious quantity of vapours muſt diſplace the air, and repel it on all ſides. Indeed many obſervations of the deſcent of Lightning, confirm his theory of the manner of its aſcent; for it often throws before it the parts of conducting bodies, and diſtributes them along the reſiſting medium, through which it muſt force its paſſage; and upon this principle the longeſt flaſhes of Lightning ſeem to be made, by forcing into its way part of the vapours in the air. One of the chief reaſons why theſe flaſhes make ſo long a rumbling, is that they are occaſioned by the vaſt length of a vacuum made by the paſſage of the electric matter: for although the air collapſes the moment after it has paſſed, and that the vibration, on which the ſound depends, commences at the ſame moment; yet when the flaſh is directed towards the perſon who hears the report, the vibrations excited at the nearer end of the track, will reach his ear much ſooner than thoſe from the more remote end; and the ſound will, without any echo or repercuſſion, continue till all the vibrations have ſucceſſively reached him.

How it happens that particular parts of the earth, or the clouds, come into the oppoſite ſtates of poſitive and negative electricity, is a queſtion not abſolutely determined: though it is eaſy to conceive that when particular clouds, or different parts of the earth, poſſeſs oppoſite

poſite electricities, a diſcharge will take place within a certain diſtance; or the one will ſtrike into the other, and in the diſcharge a flaſh of Lightning will be ſeen. Mr. Canton queries whether the clouds do not become poſſeſſed of electricity by the gradual heating and cooling of the air; and whether air ſuddenly rarefied, may not give electric fire to clouds and vapours paſſing through it, and air ſuddenly condenſed receive electric fire from them.——Mr. Wilcke ſuppoſes, that the air contracts its electricity in the ſame manner that ſulphur and other ſubſtances do, when they are heated and cooled in contact with various bodies. Thus, the air being heated or cooled near the earth, gives electricity to the earth, or receives it from it; and the electrified air, being conveyed upwards by various means, communicates its electricity to the clouds.—Others have queried, whether, ſince thunder commonly happens in a ſultry ſtate of the air, when it ſeems charged with ſulphureous vapours, the electric matter then in the clouds may not be generated by the fermentation of ſulphureous vapours with mineral or acid vapours in the air.

With regard to places of ſafety in times of thunder and Lightning, Dr. Franklin's advice is, to ſit in the middle of a room, provided it be not under a metal luſtre ſuſpended by a chain, ſitting on one chair, and laying the feet on another. It is ſtill better, he ſays, to bring two or three mattreſſes or beds into the middle of the room, and folding them double, to place the chairs upon them; for as they are not ſo good conductors as the walls, the Lightning will not be ſo likely to paſs through them: but the ſafeſt place of all, is in a hammock hung by ſilken cords, at an equal diſtance from all the ſides of a room. Dr. Prieſtley obſerves, that the place of moſt perfect ſafety muſt be the cellar, and eſpecially the middle of it; for when a perſon is lower than the ſurface of the earth, the Lightning muſt ſtrike it before it can poſſibly reach him. In the fields, the place of ſafety is within a few yards of a tree, but not quite near it. Beccaria cautions perſons not always to truſt too much to the neighbourhood of a higher or better conductor than their own body; ſince he has repeatedly found that the Lightning by no means deſcends in one undivided track, but that bodies of various kinds conduct their ſhare of it at the ſame time, in proportion to their quantity and conducting power. See Franklin's Letters, Beccaria's Lettre dell' Ellettriceſſimo, Prieſtley's Hiſt. of Electric., and Lord Mahon's Principles of Electricity.

Lord Mahon obſerves that damage may be done by Lightning, not only by the main ſtroke and lateral exploſion, but alſo by what he calls the returning ſtroke; by which is meant the ſudden violent return of that part of the natural ſhare of electricity which had been gradually expelled from ſome body or bodies, by the ſuperinduced elaſtic electrical preſſure of the electrical atmoſphere of a thunder cloud.

Artificial LIGHTNING, an imitation of real or natural Lightning by gunpowder, aurum fulminans, phoſphorus, &c, but eſpecially the laſt, between which and Lightning there is much more reſemblance than the others.

Phoſphorus, when newly made, gives a ſort of artificial Lightning viſible in the dark, which would ſurpriſe thoſe not uſed to ſuch a phenomenon. It is uſual to keep this preparation under water; and if it is deſired to ſee the corruſcations to the greateſt advantage, it ſhould be kept in a deep cylindrical glaſs, not more than three quarters filled with water. At times the phoſphorus will ſend up corruſcations, which will pierce through the incumbent water, and expand themſelves with great brightneſs in the upper or empty part of the glaſs, and much reſembling Lightning. The ſeaſon of the year, as well as the newneſs of the phoſphorus, muſt concur to produce theſe flaſhes; for they are as common in winter as Lightning is, though both are very frequent in warm weather. The phoſphorus, while burning, acts the part of a corroſive, and when it goes out reſolves into a menſtruum, which diſſolves gold, iron, and other metals; and Lightning, in like manner, melts the ſame ſubſtances.

LIKE QUANTITIES, or *Similar Quantities*, in Algebra, are ſuch as are expreſſed by the ſame letters, to the ſame power, or equally repeated in each quantity; though the numeral coefficients may be different.

Thus $4a$ and $5a$ are Like quantities,
as are alſo $3a^2$ and $12a^2$,
and alſo $6bxy^2$ and $10bxy^2$.

But $4a$ and $5b$, or $3a^2b$ and $10a^2b^2$, &c, are unlike quantities; becauſe they have not every where the ſame dimenſions, nor are the letters equally repeated. —Like quantities can be united into one quantity, by addition or ſubtraction; but unlike quantities can only be added or ſubtracted by placing the ſigns of theſe operations between them.

LIKE *Signs*, in Algebra, are the ſame ſigns, either both poſitive or both negative. But when one is poſitive and the other negative, they are unlike ſigns.

So, $+ 3ab$ and $+ 5cd$ have Like ſigns,
as have alſo $- 2a^2c$ and $- 2ax^2$;
but $+ 3ab$ and $- 5cd$ have unlike ſigns,
as alſo $- 2ax$ and $3ax$.

LIKE *Figures*, or *Arches*, &c, are the ſame as *Similar* figures, arches, &c. See SIMILAR.

All Like figures have their homologous lines in the ſame ratio. Alſo Like plane figures are in the duplicate ratio, or as the ſquares of their homologous lines or ſides; and Like ſolid figures are in the triplicate ratio, or as the cubes of their homologous lines or ſides.

LILLY (WILLIAM), a noted Engliſh aſtrologer, born in Leiceſterſhire in 1602. His father was not able to give him farther education than common reading and writing; but young Lilly, being of a forward temper, and endued with ſhrewd wit, he reſolved to puſh his fortune in London; where he arrived in 1620, and, for a preſent ſupport, articled himſelf as a ſervant to a mantua-maker in the pariſh of St. Clement Danes. But in 1624 he moved a ſtep higher, by entering into the ſervice of Mr. Wright in the Strand, maſter of the Salters company, who not being able to write, Lilly among other offices kept his books. On the death of his maſter, in 1627, Lilly paid his addreſſes to the widow, whom he married with a fortune of 1000l. Being now his own maſter, he followed the bent of his inclinations, which led him to follow the puritanical preachers. Afterwards, turning his mind to judicial aſtrology, in 1632 he became pupil, in that art, to one Evans, a profligate

profligate Welſh parſon; and the next year gave the public a ſpecimen of his ſkill, by an intimation that the king had choſen an unlucky horoſcope for the coronation in Scotland. In 1634, getting a manuſcript copy of the *Ars Noticia* of Cornelius Agrippa, with alterations, he drank in the doctrine of the magic circle, and the invocation of ſpirits, with great eagerneſs, and practiſed it for ſome time; after which he treated the myſtery of recovering ſtolen goods, &c, with great contempt, claiming a ſupernatural ſight, and the gift of prophetical predictions; all which he well knew how to turn to good advantage.

Mean while, he had buried his firſt wife, purchaſed a moiety of 13 houſes in the Strand, and married a ſecond wife, who, joining to an extravagant temper a termagant ſpirit, which he could not lay, made him unhappy, and greatly reduced his circumſtances. With this uncomfortable yokemate he removed, in 1636, to Herſham in Surrey, where he ſtaid till 1641; when, ſeeing a proſpect of fiſhing in troubled waters, he returned to London. Here having purchaſed ſeveral curious books in this art, which were found on pulling down the houſe of another aſtrologer, he ſtudied them inceſſantly, finding out ſecrets contained in them, which were written in an imperfect Greek character; and, in 1644, publiſhed his *Merlinus Anglicus*, an almanac, which he continued annually till his death, and ſeveral other aſtrological works; devoting his pen, and other labours, ſometimes to the king's party, and ſometimes to that of the parliament, but moſtly to the latter, raiſing his fortune by favourable predictions to both parties, ſometimes by preſents, and ſometimes by penſions: thus, in 1648, the council of ſtate gave him in money 50l. and a penſion of 100l. per annum, which he received for two years, and then reſigned it on ſome diſguſt. By his advice and contrivance, the king attempted ſeveral times to make his eſcape from his confinement: he procured and ſent the aqua-fortis and files to cut the iron bars of his priſon windows at Cariſbrook caſtle; but ſtill adviſing and writing for the other party at the ſame time. Mean while he read public lectures on aſtrology, in 1648 and 1649, for the improvement of young ſtudents in that art; and in ſhort, plied his buſineſs ſo well, that in 1651 and 1652 he laid out near 2000l. for lands and a houſe at Herſham.

During the ſiege of Colcheſter, he and Booker were ſent for thither, to encourage the ſoldiers; which they did by aſſuring them that the town would ſoon be taken; which proved true in the event.—Having, in 1650, written publicly that the parliament ſhould not continue, but a new government ariſe; agreeably to which, in his almanac for 1653, he aſſerted that the parliament ſtood upon a tickliſh foundation, and that the commonalty and ſoldiery would join together againſt them. Upon which he was ſummoned before the committee of plundered miniſters; but, receiving notice of it before the arrival of the meſſenger, he applied to his friend Lenthal the ſpeaker, who pointed out the offenſive paſſages. He immediately altered them; attended the committee next morning, with 6 copies printed, which ſix alone he acknowledged to be his; and by that means came off with only 13 days cuſtody by the ſerjeant at arms. This year he was engaged in a diſpute with Mr. Thomas Gataker.—In 1665 he was indicted at Hicks's-hall, for giving judgment upon ſtolen goods; but was acquitted. And in 1659, he received, from the king of Sweden, a preſent of a gold chain and medal, worth about 50l. on account of his having mentioned that monarch with great reſpect in his almanacs of 1657 and 1658.—After the Reſtoration, in 1660, being taken into cuſtody, and examined by a committee of the houſe of commons, touching the execution of Charles the 1ſt, he declared, that Robert Spavin, then Secretary to Cromwell, dining with him ſoon after the fact, aſſured him it was done by cornet Joyce. The ſame year he ſued out his pardon under the broad ſeal of England; and afterwards continued in London till 1665; when, upon the raging of the plague there, he retired to his eſtate at Herſham. Here he applied himſelf to the ſtudy of phyſic, having, by means of his friend Elias Aſhmole, procured from archbiſhop Sheldon a licence to practiſe it, which he did, as well as aſtrology, from thence till the time of his death.—In October 1666 he was examined before a committee of the houſe of commons concerning the fire of London, which happened in September that year. A little before his death, he adopted for his ſon, by the name of *Merlin junior*, one Henry Coley, a taylor by trade; and at the ſame time gave him the impreſſion of his almanac, which had been printed for 36 years ſucceſſively. This Coley became afterwards a celebrated aſtrologer, publiſhing in his own name, almanacs, and books of aſtrology, particularly one intitled *A Key to Aſtrology*.

Lilly died of a palſy 1681, at 79 years of age; and his friend Mr. Aſhmole placed a monument over his grave in the church of Walton upon Thames.

Lilly was author of many works. His *Obſervations on the Life and Death of Charles late King of England*, if we overlook the aſtrological nonſenſe, may be read with as much ſatisfaction as more celebrated hiſtories; Lilly being not only very well informed, but ſtrictly impartial. This work, with the Lives of Lilly and Aſhmole, written by themſelves, were publiſhed in one volume, 8vo, in 1774, by Mr. Burman. His other works were principally as follow:

1. Merlinus Anglicus junior.—2. Supernatural Sight.—3. The White King's Prophecy.—4. England's Prophetical Merlin: all printed in 1644.—5. The Starry Meſſenger, 1645.—6. Collection of Prophecies, 1646.—7. A Comment on the White King's Prophecy, 1646.—8. The Nativities of Archbiſhop Laud and Thomas earl of Strafford, 1646.—9. Chriſtian Aſtrology, 1647: upon this piece he read his lectures in 1648, mentioned above.—10. The third book of Nativities, 1647.—11. The World's Cataſtrophe, 1647.—12. The Prophecies of Ambroſe Merlin, with a Key, 1647.—13. Trithemius, or the Government of the World by Preſiding Angels, 1647.—14. A treatiſe of the Three Suns ſeen in the winter of 1647, printed in 1648.—15. Monarchy or no Monarchy, 1651.—16. Obſervations on the Life and Death of Charles, late king of England, 1651; and again in 1651, with the title of Mr. William Lilly's True Hiſtory of king James and king Charles the 1ſt, &c.—17. Annus Tenebroſus; or, the Black Year. This drew him into the diſpute with Gataker, which Lilly carried on in his Almanac in 1654.

LIMB, the outermoſt border, or graduated edge, of a quadrant, aſtrolabe, or ſuch like mathematical inſtrument.

The word is alſo uſed for the arch of the primitive circle, in any projection of the ſphere in plano.

Limb alſo ſignifies the outermoſt border or edge of the ſun or moon; as the upper Limb, or edge; the lower Limb; the preceding Limb, or ſide; the following Limb.—Aſtronomers obſerve the upper or lower Limb of the ſun or moon, to find their true height, or that of the centre, which differs from the others by the ſemidiameter of the diſc.

LIMBERS, in Artillery, a ſort of advanced train, joined to the carriage of a cannon on a march. It is compoſed of two ſhafts, wide enough to receive a horſe between them, called the *fillet horſe*: theſe ſhafts are joined by two bars of wood, and a bolt of iron at one end, and mounted on a pair of rather ſmall wheels. Upon the axle-tree riſes a ſtrong iron ſpike, which is put into a hole in the hinder part of the train of the gun-carriage, to draw it by. But when a gun is in action, the Limbers are taken off, and run out behind it.—See the dimenſions and figure of it in Müller's Treatiſe of Artillery, pa. 187.

LIMIT, is a term uſed by mathematicians, for ſome determinate quantity, to which a variable one continually approaches, and may come nearer to it than by any given difference, but can never go beyond it; in which ſenſe a circle may be ſaid to be the Limit of all its inſcribed and circumſcribed polygons: becauſe theſe, by increaſing the number of their ſides, can be made to be nearer equal to the circle than by any ſpace that can be propoſed, how ſmall ſoever it may be.

In Algebra, the term *Limit* is applied to two quantities, of which the one is greater and the other leſs than ſome middle quantity, as the root of an equation, &c. And in this ſenſe it is uſed when ſpeaking of the Limits of equations, a method by which their ſolution is greatly facilitated.

Limit *of Diſtinct Viſion*, in Optics. See *Diſtinct* Vision.

Limit *of a Planet*, has been ſometimes uſed for its greateſt heliocentric latitude.

Limited *Problem*, denotes a problem that has but one ſolution, or ſome determinate number of ſolutions: as to deſcribe a circle through three given points that do not lie in a right line, which is limited to one ſolution only; to divide a parallelogram into two equal parts by a line parallel to one ſide, which admits of two ſolutions, according as the line is parallel to the length or breadth of the parallelogram; or to divide a triangle in any ratio by a line parallel to one ſide, which is limited to three ſolutions, as the line may be parallel to any of the three ſides.

LINE, in Geometry, a quantity extended in length only, without either breadth or thickneſs.

A Line is ſometimes conſidered as generated by the flux or motion of a point; and ſometimes as the limit or termination of a ſuperficies, but not as any part of that ſurface, however ſmall.

Lines are either *right* or *curved*. A *right*, or ſtraight Line, is the neareſt diſtance between two points, which are its extremes or ends; or it is a Line which has in every part of it the ſame direction or poſition. But a *curve Line* has in every part of it a different direction, and is not the ſhorteſt diſtance between its extremes or ends.

Right Lines are all of the ſame ſpecies; but curves are of an infinite number of different ſorts. As many may be conceived as there are different compound motions, or as many as there may be different relations between their ordinates and abſciſſes. See Curves.

Again, *Curve* Lines are uſually divided into *geometrical* and *mechanical*.

Geometrical Lines, are thoſe which may be found exactly in all their parts. See Geometrical Line.

Mechanical Lines are ſuch as are not determined exactly in all their parts, but only nearly, or tentatively. But

Des Cartes, and his followers, define geometrical Lines to be thoſe which may be expreſſed by an algebraical equation of a determinate or finite degree; called its *locus*. And mechanical Lines, ſuch as cannot be expreſſed by ſuch an equation.

But others diſtinguiſh the ſame Lines by the name *algebraical* and *tranſcendental*.

Lines are alſo divided into orders, by Newton, according to the number of interſections which may be made by them and a right Line, viz, the 1ſt, 2d, 3d, 4th, &c, order, according as they may be cut by a right Line, in 1, or 2, or 3, or 4, &c, points. In this way of conſidering them, the right Line only is of the 1ſt order, being but one in number; the 2d order contains 4 curves only, being ſuch as may be cut from a cone by a plane, viz, the circle, the ellipſe, the hyperbola, and the parabola; the lines of the 3d order have been enumerated by Newton, in a particular treatiſe, who makes their number amount to 72; but Mr. Stirling found 4 others, and Mr. Stone 2 more; though it is diſputed by ſome whether theſe 2 laſt ought to be accounted different from ſome of Newton's, or not. See Newton's Enumer. Lin. Tertii Ordin. alſo Stirling's Lineæ Tert. Ordin. Newtonianæ Oxon. 1717, 8vo. and Philoſ. Tranſ. number 456, &c. Again,

Algebraical Lines are divided into different orders according to the power or degree of their equations. So, the ſimple equation $a + by + cx = 0$ or equation of the 1ſt degree, denotes the 1ſt order or right line; the equation $a + by + cx + dyy + exy + fxx = 0$, of the 2d degree, denotes the Lines of the 2d order; and the equation

$a + by + cx + dyy + exy + fxx + gy^3 + hxy^2 + ix^2y + kx^3 = 0$

of the 3d degree, expreſſes the Lines of the 3d order; and ſo on. See Cramer's Introd. à l'Analyſe des Lignes Courbes.

Lines, conſidered as to their poſitions, are either *parallel*, *perpendicular*, or *oblique*. And the conſtruction and properties of each of theſe, ſee under the reſpective terms.

Line alſo denotes a French meaſure of length, being the 12th part of an inch, or the 144th part of a foot.

In *Aſtronomy*,

Line *of the Apſes*, or *Apſides*, the Line joining the two apſes, or the longer axis of the orbit of a planet.

Fiducial Line, the index line or edge of the ruler, which paſſes through the middle of an aſtrolabe, or other inſtrument, on which the ſights are fitted, and marking the diviſions.

Horizontal

Horizontal Line, a Line parallel to the horizon.

LINE *of the Nodes*, that which joins the nodes of the orbit of a planet, being the common ſection of the plane of the orbit with the plane of the ecliptic.

In *Dialling*,

Horizontal Line, is the common ſection of the horizon and the dial-plate.

Horary, or *Hour Lines*, are the common interſections of the hour-circles of the ſphere with the plane of the dial.

Equinoctial Line is the common interſection of the equinoctial and the plane of the dial.

In *Fortification*, *Line* is ſometimes uſed for a ditch, bordered with its parapet: and ſometimes for a row of gabions, or ſacks of earth, extended lengthwiſe on the ground, to ſerve as a ſhelter againſt the enemy's fire.

When the trenches were carried on within 30 paces of the glacis, they drew two Lines, one on the right, and the other on the left, for a place of arms.

Lines are commonly made to ſhut up an avenue or entrance to ſome place; the ſides of the entrance being covered by rivers, woods, mountains, moraſſes, or other obſtructions, not eaſy to be paſſed over by an army. When they are conſtructed in an open country, they are carried round the place to be defended, and reſemble the Lines ſurrounding a camp, called Lines of circumvallation. Lines are alſo thrown-up to ſtop the progreſs of an army; but the term is moſt uſed for the Line which covers a paſs that can only be attacked in front.

When lines are made to cover a camp, or a large tract of land, where a conſiderable body of troops is poſted, the work is not made in one ſtraight, or uniformly bending Line; but, at certain diſtances, the Lines project in ſaliant angles, called redents, redans, or flankers, towards the enemy. The diſtance between theſe angles is commonly between the limits of 200 and 260 yards; the ordinary flight of a muſket ball, point blank, being commonly within thoſe limits; though muſkets a little elevated will do effectual ſervice at the diſtance of 360 yards.

Fundamental Line, is the firſt Line drawn for the plan of a place, and which ſhews its area.

Central Line, is the Line drawn from the angle of the centre to the angle of the baſtion.

Line of Defence, &c. See DEFENCE &c.

Line of Approach, or *Attack*, ſignifies the work which the beſiegers carry on under cover, to gain the moat, and the body of the place.

Line of Circumvallation, is a Line or trench cut by the beſiegers, within cannon-ſhot of the place, which ranges round the camp, and ſecures its quarters againſt any relief to be brought to the beſieged.

Line of Contravallation, is a ditch bordered with a parapet, ſerving to cover the beſiegers on the ſide next the place, and to ſtop the ſallies of the garriſon.

Lines of Communication are thoſe which run from one work to another.

Line of the Baſe, is that which joins the points of the two neareſt baſtions.

To *Line* a work, ſignifies to face it, as with brick or ſtone; for example, to ſtrengthen a rampart with a firm wall, or to encompaſs a parapet or moat with good turf, &c.

LINE, in Geography and Navigation, is emphatically uſed for the Equator or Equinoctial Line.

The ſeamen uſe to baptize their freſh men, and paſſengers, the firſt time they croſs the Line: that is, to dip them in the ſea, ſuſpended by a rope from the yard-arm, unleſs they compound for it, by giving ſomething to drink.

In *Perſpective*,

The *Geometrical Line*, is a right Line drawn in any manner on the geometrical plane.

Terreſtrial or *Fundamental Line*, is the common interſection of the geometrical plane and plane of the picture.

Line of the Front, is any Line parallel to the terreſtrial Line.

Vertical Line, is the ſection of the vertical and draft planes.

Viſual Line, is the Line or ray conceived to paſs from the object to the eye.

Objective Line, is any Line drawn on the geometrical plane, whoſe repreſentation is ſought for in the draught or picture.

Line of Meaſures, is uſed by Oughtred, and others, to denote the diameter of the primitive circle, in the projection of the ſphere in plano, or that Line in which falls the diameter of any circle to be projected.

LINEAR NUMBERS, are ſuch as have relation to length only; ſuch, for example, as expreſs one ſide of a plane figure; and when the plane figure is a ſquare, the linear number is called a root.

LINEAR PROBLEM, is one that can be ſolved geometrically by the interſection of two right lines. This is called a ſimple problem, and is capable of only one ſolution.

LIQUID, a fluid which wets or ſmears ſuch bodies as are immerſed in it, ariſing from ſome configuration of its particles, which diſpoſes them to adhere to the ſurfaces of bodies contiguous to them. Thus water, oil, milk, &c, are Liquids, as well as fluids; but quickſilver is not a Liquid, but ſimply a fluid.

LISLE (WILLIAM DE), a very learned French geographer, was born at Paris in 1675. His father being much occupied in the ſame way, young Liſle began at 9 years of age to draw maps, and ſoon made a great progreſs in this art. In 1699 he firſt diſtinguiſhed himſelf to the public, by giving a map of the world, and other pieces, which procured him a place in the Academy of Sciences, 1702. He was afterwards appointed geographer to the king, with a penſion, and had the honour of inſtructing the king himſelf in geography, for whoſe particular uſe he drew up ſeveral works. De Liſle's reputation was ſo great, that ſcarcely any hiſtory or travels came out without the embelliſhment of his maps. Nor was his name leſs celebrated abroad than in his own country. Many ſovereigns in vain attempted to draw him out of France. The Czar Peter, when at Paris on his travels, paid him a viſit, to communicate to him ſome remarks upon Muſcovy; but more eſpecially, ſays Fontenelle, to learn from him, better than he could any where elſe, the extent and ſituation of his own dominions. De Liſle died of an apoplexy in 1726, at 51 years of age. Beſide the excellent maps he publiſhed, he wrote

many pieces in the Memoirs of the Academy of Sciences.

LIST, or LISTEL, a ſmall ſquare moulding, ſerving to crown or accompany larger mouldings; or on occaſion to ſeparate the flutings of columns.

LITERAL ALGEBRA. See ALGEBRA.

LIZARD, in Aſtronomy. See LACERTA.

LOADSTONE, or MAGNET; which ſee.

LOCAL *Problem*, is one that is capable of an infinite number of different ſolutions; becauſe the point, which is to ſolve the problem, may be indifferently taken within a certain extent; as ſuppoſe any where in ſuch a line, within ſuch a plane figure, &c, which is called a *geometrical Locus*.

A Local problem is *ſimple*, when the point ſought is in a right line; *plane*, when the point ſought is in the circumference of a circle; *ſolid*, when it is in the circumference of a conic ſection; or *ſurſolid*, when the point is in the perimeter of a line of a higher kind.

LOCAL MOTION, or *Loco-Motion*, the change of place: See MOTION.

LOCI, the plural of LOCUS, which ſee.

LOCUS, is ſome line by which a local or indeterminate problem is ſolved; or a line of which any point may equally ſolve an indeterminate problem.

Loci are expreſſed by algebraic equations of different orders according to the nature of the Locus. If the equation is conſtructed by a right line, it is called *Locus ad rectum*; if by a circle, *Locus ad circulum*; if by a parabola, *Locus ad parabolam*; if by an ellipſis, *Locus ad ellipſim*; and ſo on.

The Loci of ſuch equations as are right lines or circles, the ancients called *plane loci*; and of thoſe that are conic ſections, *ſolid loci*; but ſuch as are curves of a higher order, *ſurſolid loci*. But the moderns diſtinguiſh the Loci into orders according to the dimenſions of the equations by which they are expreſſed, or the number of the powers of indeterminate or unknown quantities in any one term: thus, the equation

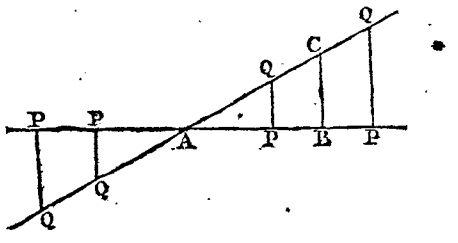
$ay = bx + c$ denotes a Locus of the 1ſt order,

but $y^2 = ax$, or $= ax - x^2$, &c, a Locus of the 2d order,

and $y^3 = a^2x$, or $= ax^2 - x^3$, &c, a Locus of the 3d order,

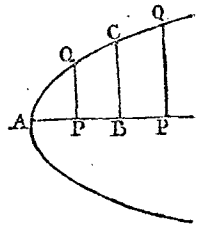
and ſo on; where x and y are unknown or indeterminate quantities, and the others known or determinate ones; alſo x denotes the abſciſs, and y the ordinate of the curve or line which is the Locus of the equation.

For inſtance, ſuppoſe two variable or indeterminate right lines AP, AQ, making any given angle PAQ between

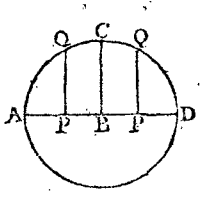


them, where they are ſuppoſed to commence, and to extend indefinitely both ways from the point A: then calling any AP, x, and its correſponding ordinate PQ, y, continually changing its poſition by moving parallel to itſelf along the indefinite line AP; alſo in the line AP aſſume AB $= a$, and from B draw BC parallel to PQ and $= b$: then the indefinite line AQ is called in general a geometrical Locus, and in particular the Locus of the equation $y = \frac{bx}{a}$; for whatever point Q is, the triangles ABC, APQ are always ſimilar, and therefore AB : BC :: AP : PQ, that is $a : b :: x : y$, and therefore $y = \frac{bx}{a}$ is the equation to the right line AQ, or AQ is the Locus of the equation $y = \frac{bx}{a}$.

Again, if AQ be a parabola, the nature of which is ſuch, that AB : AP :: BC^2 : PQ^2, or $a : x :: b^2 : y^2$, and therefore $y^2 = \frac{b^2x}{a}$ is the equation which has the parabola for its Locus, or the parabola is the Locus to every equation of this form $y^2 = \frac{b^2x}{a}$.



Or if AQ be a circle, having its radius AB $= a$, the nature of which is this, that $PQ^2 =$ AP . PD, or $y^2 = x \cdot 2a - x$ or $2ax - x^2$; therefore the Locus of the equation of this form $y^2 = 2ax - x^2$, is always a circle.



In like manner it will appear, that the ellipſe is the Locus to the equation $y^2 = \frac{e^2}{t^2} \times \overline{tx - x^2}$, and the hyperbola the Locus to the equation $y^2 = \frac{e^2}{t^2} \times \overline{tx + x^2}$; where t is the tranſverſe, and e the conjugate axis of the ellipſe or hyperbola.

All equations, whoſe Loci are of the firſt order, may be reduced to one of the 4 following forms:

$$1\text{ſt } y = \frac{bx}{a};\ 2\text{d } y = \frac{bx}{a} + c;\ 3\text{d } y = \frac{bx}{a} - c;\ 4\text{th } y = c - \frac{bx}{a};$$

where the letter c denotes the diſtance that the ordinates commence from the line AP, either on the one ſide or the other of it, according as the ſign of that quantity is + or —.

All Loci of the 2d degree are conic ſections, viz, either the parabola, the circle, ellipſis, or hyperbola. Therefore when an equation is given, whoſe Locus is of the 2d degree, and it is required to draw that Locus, or, which is the ſame thing, to conſtruct the equation generally; bring over all the terms of the equation to one ſide, ſo that the other ſide be 0; then to know which of the conic ſections it denotes, there will be two general caſes, viz, either when the rectangle xy is in the equation, or when it is not in it.

Caſe 1. When the term xy is not in the propoſed equation. Then, 1ſt, if only one of the ſquares

x^2, y^2

x^2, y^2 be found in it, the Locus will be a parabola. 2d, If both the ſquares be in it, and if they have the ſame ſign, the Locus will be a circle or an ellipſe. 3d, But if the ſigns of the ſquares x^2, y^2 be different, the Locus will be an hyperbola, or the oppoſite hyperbolas.

Caſe 2. When the rectangle xy is in the propoſed equation; then 1ſt, If neither of the ſquares x^2, y^2, or only one of them be in the equation, the Locus will be an hyperbola between the aſymptotes. 2d, If both x^2 and y^2 be in it, having different ſigns, the Locus will be an hyperbola, having the abſciſſes on its diameter. 3d, If both the ſquares be in it, and with the ſame ſign, then if the coefficient of x^2 be greater than the ſquare of half the coefficient of xy, the Locus will be an ellipſe; if equal, a parabola; and if leſs, an hyperbola.

This method of determining geometric Loci, by reducing them to the moſt compound or general equations, was firſt publiſhed by Mr. Craig, in his Treatiſe on the Quadrature of Curves, in 1693. It is explained at large in the 7th and 8th books of l'Hoſpital's Conic Sections. See this ſubject particularly illuſtrated in Maclaurin's Algebra. The method of Des Cartes, of finding the Loci of equations of the 2d order, is a good one, viz, by extracting the root of the equation. See his Geometry; as alſo Stirling's Illuſtratio Linearum Tertii Ordinis. The doctrine of theſe Loci is likewiſe well treated by De Witt in his Elementa Curvarum. And Bartholomæus Intieri, in his Aditus ad Nova Arcana Geometrica delegenda, has ſhewn how to find the Loci of equations of the higher orders. Mr. Stirling too, in his treatiſe above-mentioned, has given an example or two of finding the Loci of equations of 3 dimenſions. Euclid, Apollonius, Ariſtæus, Fermat, Viviani, have alſo written on the ſubject of Loci.

LOG, in Navigation, is a piece of thin board, of a ſectoral or quadrantal form, loaded in the circular ſide with lead ſufficient to make it ſwim upright in the water; to which is faſtened a line of about 150 fathoms, or 300 yards long, called the Log-line, which is divided into certain ſpaces, called Knots, and wound on a reel which turns very freely, for the line to wind eaſily off.

The uſe of the Log, or Log-line, is to meaſure the velocity of the ſhip, or rate at which ſhe runs, which is done from time to time, as the foundation upon which the ſhip's reckoning, or finding her place, is kept; and the practice is to heave the Log into the ſea, with the line tied to it, and obſerve how much of the line is run off the reel, while the ſhip ſails, during the ſpace of half a minute, which time is meaſured by a ſand-glaſs made to run that time very exactly. About 10 fathoms of ſtray or waſte line is left next the Log before the knotting or counting commence, that ſpace being uſually allowed to carry the Log out of the eddy of the ſhip's wake.

The uſing of the Log for finding the velocity of the ſhip, is called *Heaving the Log*, and is thus performed: One man holds the reel, and another the half-minute glaſs; an officer of the watch throws the Log over the ſhip's ſtern, on the lee-ſide, and when he obſerves the ſtray line, and the firſt mark is going off, he cries *turn!* when the glaſs-holder inſtantly turns the glaſs crying out *done!* then watching the glaſs, the moment it is run out he ſays *ſtop!* upon which the reel being quickly ſtopt, the laſt mark run off ſhews the number of knots, and the diſtance of that mark from the reel is eſtimated in fathoms: then the knots and fathoms together ſhew the diſtance run in half a minute, or the diſtance per hour nearly, by conſidering the knots as miles, and the fathoms as decimals of a mile: thus if 7 knots and 4 fathoms be obſerved, then the ſhip runs at the rate of 7·4 miles an hour.

It follows, therefore, that the length of each knot, or diviſion of the line, ought to be the ſame part of a ſea mile, as half a minute is of an hour, that is $\frac{1}{120}$th part. Now it is found that a degree of the meridian contains nearly 366,000 feet, therefore $\frac{1}{60}$ of this, or a nautical mile, will be 6100 feet; the $\frac{1}{120}$th of which, or 51 feet nearly, ſhould be the length of each knot, or diviſion of the Log-line. But becauſe it is ſafer to have the reckoning rather before the ſhip than after it, therefore it is uſual now to make each knot equal to 8 fathoms or 48 feet. But the knots are made ſometimes to contain only 42 feet; and this method of dividing the Log-line was founded on the ſuppoſition, that 60 miles, of 5000 feet each, made a degree; for $\frac{1}{120}$th of 5000 is $41\frac{2}{3}$, or in round numbers 42 feet. And although many mariners find by experience that this length of the knot is too ſhort, yet rather than quit the old way, they uſe ſand-glaſſes for half-minute ones that run only 24 or 25 ſeconds. The ſand, or half-minute glaſs, may be tried by a pendulum vibrating ſeconds, in the following manner: On a round nail or peg, hang a thread or fine ſtring that has a muſket ball fixed to one end, carefully meaſuring between the centre of the ball and the ſtring's loop over the nail $39\frac{1}{8}$ inches, being the length of a ſecond pendulum; then make it ſwing or vibrate very ſmall arches, and count one for every time it paſſes under the nail, beginning at the ſecond time it paſſes; and the number of ſwings made during the time the glaſs is running out, ſhews the ſeconds in the glaſs.

It is not known who was the inventor of this method of meaſuring the ſhip's way, or her rate of ſailing; but no mention of it occurs till the year 1607, in an Eaſt-India voyage, publiſhed by Purchas; and from that time its name occurs in other voyages in his collections; after which it became famous, being noticed both by our own authors, and by foreigners; as by Gunter in 1623; Snellius, in 1624; Metius, in 1631; Oughtred, in 1633; Herigone, in 1634; Saltonſtall, in 1636; Norwood, in 1637; Fournier, in 1643; and almoſt all the ſucceeding writers on navigation of every country. Various improvements have lately been made of this inſtrument by different perſons.

LOGARITHM, from the Greek λογος *ratio*, and αριθμος *number*; q. d. *ratio of numbers*, or perhaps rather *number of ratios*; the indices of the ratios of numbers to one another; or a ſeries of numbers in arithmetical proportion, correſponding to as many others in geometrical proportion, in ſuch ſort that 0 correſponds to, or is the index of 1, in the geometricals. They have been deviſed for the eaſe of large arithmetical calculations.

Thus

Thus,

0, 1, 2, 3, 4, &c,	indices or Logarithms,
1, 2, 4, 8, 16, &c,	the geometrical progreſſions, or common numbers.
or 2^0, 2^1, 2^2, 2^3, 2^4, &c,	
1, 3, 9, 27, 81, &c,	
or 3^0, 3^1, 3^2, 3^3, 3^4, &c,	
1, 10, 100, 1000, 10000, &c,	
or 10^0, 10^1, 10^2, 10^3, 10^4, &c,	

Where the ſame indices, or Logarithms, ſerve equally for any geometric ſeries; and from which it is evident, that there may be an endleſs variety of ſets of Logarithms to the ſame common numbers, by varying the 2d term 2, or 3, or 10, &c of the geometric ſeries; as this will change the original ſeries of terms whoſe indices are the numbers 1, 2, 3, &c; and by interpolation the whole ſyſtem of numbers may be made to enter the geometrical ſeries, and receive their proportional Logarithms, whether integers or decimals.

Or the Logarithm of any given number, is the index of ſuch a power of ſome other number, as is equal to the given one. So if N be $= r^n$, then the Logarithm of N is n, which may be either poſitive or negative, and r any number whatever, according to the different ſyſtems of Logarithms. When N is 1, then n is $= 0$, whatever the value of r is; and conſequently the Logarithm of 1 is always 0 in every ſyſtem of Logarithms. When n is $= 1$, then N is $= r$; conſequently the root r is always the number whoſe Logarithm is 1, in every ſyſtem. When r is $=$ 2·718281828459 &c, the indices are the hyperbolic Logarithms; ſo that n is always the hyperbolic Logarithm of $\overline{2\cdot718\ \&c})^n$. But in the common Logarithms, r is $= 10$; ſo that the common Logarithm of any number, is the index of that power of 10 which is equal to the ſaid number; ſo the common Logarithm of $N = 10^n$, is n the index of the power of 10; for example, 1000, being the 3d power of 10, has 3 for its Logarithm; and if 50 be $= 10^{1\cdot69897}$, then is 1·69897 the common Logarithm of 50. And hence it follows that this decimal ſeries of terms

1000, 100, 10, 1, ·1, ·01, ·001,
or 10^3, 10^2, 10^1, 10^0, 10^{-1}, 10^{-2}, 10^{-3},
have 3, 2, 1, 0, −1, −2, −3,
reſpectively for the Logarithms of thoſe terms.

The Logarithm of a number contained between any two terms of the firſt ſeries, is included between the two correſponding terms of the latter; and therefore that Logarithm will conſiſt of the ſame index, whether poſitive or negative, as the ſmaller of thoſe two terms, together with a decimal fraction, which will always be poſitive. So the number 50 falling between 10 and 100, its Logarithm will fall between 1 and 2, being indeed equal to 1·69897 nearly: alſo the number ·05 falling between the terms ·1 and ·01, its Logarithm will fall between −1 and −2, and is indeed $= -2 + \cdot69897$, the index of the leſs term together with the decimal ·69897. The index is alſo called the Characteriſtic of the Logarithms, and is always an integer, either poſitive or negative, or elſe $= 0$; and it ſhews what place is occupied by the firſt ſignificant figure of the given number, either above or below the place of units, being in the former caſe + or poſitive; in the latter − or negative.

When the characteriſtic of a Logarithm is negative, the ſign − is commonly ſet over it, to diſtinguiſh it from the decimal part, which, being the Logarithm found in the tables, is always poſitive: ſo $-2 + \cdot69897$, or the Logarithm of ·05, is written thus $\overline{2}\cdot69897$. But on ſome occaſions it is convenient to reduce the whole expreſſion to a negative form; which is done by making the characteriſtic leſs by 1, and taking the *arithmetical complement* of the decimal, that is, beginning at the left hand, ſubtract each figure from 9, except the laſt ſignificant figure, which is ſubtracted from 10; ſo ſhall the remainders form the Logarithm wholly negative: thus the Logarithm of ·05, which is $\overline{2}\cdot69897$ or $-2 + \cdot69897$, is alſo expreſſed by $-1\cdot30103$, which is all negative. It is alſo ſometimes thought more convenient to expreſs ſuch Logarithms entirely as poſitive, namely by only joining to the tabular decimal the complement of the index to 10; and in this way the above Logarithm is expreſſed by 8·69897; which is only increaſing the indices in the ſcale by 10.

The Properties of Logarithms.—From the definition of Logarithms, either as being the indices of a ſeries of geometricals, or as the indices of the powers of the ſame root, it follows that the multiplication of the numbers will anſwer to the addition of their Logarithms; the diviſion of numbers, to the ſubtraction of their Logarithms; the raiſing of powers, to the multiplying the Logarithm of the root by the index of the power; and the extracting of roots, to the dividing the Logarithm of the given number by the index of the root required to be extracted.

So, 1ſt,

Log. ab or of $a \times b$ is $=$ log. a + log. b,
Log. 18 or of 3×6 is $=$ log. 3 + log. 6,
Log. $5 \times 9 \times 73$ is $=$ log. 5 + log. 9 + log. 73.

Secondly,

Log. $a \div b$ is $=$ log. a − log. b,
Log. $18 \div 6$ is $=$ log. 18 − log. 6,
Log. $79 \times 5 \div 9$ is $=$ log. 79 + log. 5 − log. 9,
Log. $\frac{1}{2}$ or $1 \div 2$ is $=$ l. 1 − l. 2 $=$ 0 − l. 2 $=$ − l. 2,
Log. $\frac{1}{n}$ or $1 \div n$ is $=$ l. 1 − l. n $=$ − l. n.

Thirdly,

Log. r^n is $= n$ l. r; Log. $r^{\frac{1}{n}}$ or of $\sqrt[n]{r}$ is $= \frac{1}{n}$ l. r;
Log. $r^{\frac{m}{n}}$ is $= \frac{m}{n}$ l. r; Log. 2^6 is $=$ 6l. 2; log. $2^{\frac{1}{3}}$ or of $\sqrt[3]{2}$ is $= \frac{1}{3}$ l. 2; and Log. $2^{\frac{3}{4}}$ is $= \frac{3}{4}$ l. 2.

So that any number and its reciprocal have the ſame Logarithm, but with contrary ſigns; and the ſum of the Logarithms of any number and its reciprocal, or complement, is equal to 0.

Hiſtory and Conſtruction of Logarithms.—The properties of Logarithms hitherto mentioned, or of arithmetical indices to powers or geometricals, with their various uſes and properties, as above-mentioned, are taken notice of by Stifelius, in his Arithmetic; and indeed they were not unknown to the ancients; but they come all far ſhort of the uſe of Logarithms in

Trigonometry, as firſt diſcovered by John Napier, baron of Merchiſton in Scotland, and publiſhed at Edinburgh in 1614, in his Mirifici Logarithmorum Canonis Deſcriptio; which contained a large canon of Logarithms, with the deſcription and uſes of them; but their conſtruction was reſerved till the ſenſe of the Learned concerning his invention ſhould be known. This work was tranſlated into Engliſh by the celebrated Mr. Edward Wright, and publiſhed by his ſon in 1616. In the year 1619, Robert Napier, ſon of the inventor of Logarithms, publiſhed a new edition of his late father's work, together with the promiſed Conſtruction of the Logarithms, with other miſcellaneous pieces written by his father and Mr. Briggs. And in the ſame year, 1619, Mr John Speidell publiſhed his New Logarithms, being an improved form of Napier's.

All theſe tables were of the kind that have ſince been called hyperbolical, becauſe the numbers expreſs the areas between the aſymptote and curve of the hyperbola. And Logarithms of this kind were alſo ſoon after publiſhed by ſeveral other perſons; as by Urſinus in 1619, Kepler in 1624, and ſome others.

On the firſt publication of Napier's Logarithms, Henry Briggs, then profeſſor of Geometry in Greſham College in London, immediately applied himſelf to the ſtudy and improvement of them, and ſoon publiſhed the Logarithms of the firſt 1000 numbers, but on a new ſcale, which he had invented, viz, in which the Logarithm of the ratio of 10 to 1 is 1, the Logarithm of the ſame ratio in Napier's ſyſtem being 2·30258 &c; and in 1624, Briggs publiſhed his Arithmetica Logarithmica, containing the Logarithms of 30,000 natural numbers, to 14 places of figures beſides the index, in a form which Napier and he had agreed upon together, which is the preſent form of Logarithms; alſo in 1633 was publiſhed, to the ſame extent of figures, his Trigonometria Britannica, containing the natural and logarithmic ſines, tangents, &c.

With various and gradual improvements, Logarithms were alſo publiſhed ſucceſſively, by Gunter in 1620, Wingate in 1624, Henrion in 1626, Miller and Norwood in 1631, Cavalerius in 1632 and 1643, Vlacq and Rowe in 1633, Frobenius in 1634, Newton in 1658, Caramuel in 1670, Sherwin in 1706, Gardiner in 1742, and Dodſon's Antilogarithmic Canon in the ſame year; beſides many others of leſſer note; not to mention the accurate and comprehenſive tables in the Tables Portative, and in my own Logarithms lately publiſhed, where a complete hiſtory of this ſcience may be ſeen, with the various ways of conſtructing them that have been invented by different authors.

In Napier's conſtruction of Logarithms, the natural numbers, and their Logarithms, as he ſometimes called them, or at other times the artificial numbers, are ſuppoſed to ariſe, or to be generated, by the motions of points, deſcribing two lines, of which the one is the natural number, and the other its Logarithm, or artificial. Thus, he conceived the line or length of the radius to be deſcribed, or run over, by a point moving along it in ſuch a manner, that in equal portions of time it generated, or cut off, parts in a decreaſing geometrical progreſſion, leaving the ſeveral remainders, or ſines, in geometrical progreſſion alſo; whilſt another point deſcribed equal parts of an indefinite line, in the ſame equal portions of time; ſo that the reſpective ſums of theſe, or the whole line generated, were always the arithmeticals or Logarithms of the aforeſaid natural ſines. In this idea of the generation of the Logarithms and numbers, Napier aſſumed 0 as the Logarithm of the greateſt ſine or radius; and next he limited his ſyſtem, not by aſſuming a particular value to ſome aſſigned number, or part of the radius, but by ſuppoſing that the two generating points, which, by their motions along the two lines, deſcribed the natural numbers and Logarithms, ſhould have their velocities equal at the beginning of thoſe lines. And this is the reaſon that, in his table, the natural ſines and their Logarithms, at the complete quadrant, have equal differences or increments; and this is alſo the reaſon why his ſcale of Logarithms happens accidentally to agree with what have ſince been called the hyperbolical Logarithms, which have likewiſe numeral differences equal to thoſe of their natural numbers at the beginning; except only that theſe latter increaſe with the natural numbers, while his on the contrary decreaſe; the Logarithm of the ratio of 10 to 1 being the ſame in both, namely 2·30258509 &c.

Having thus limited his ſyſtem, Napier proceeds, in the poſthumous work of 1619, to explain his conſtruction of the Logarithmic canon. This he effects in various ways, but chiefly by generating, in a very eaſy manner, a ſeries of proportional numbers, and their arithmeticals or Logarithms; and then finding, by proportion, the Logarithms to the natural ſines from thoſe of the natural numbers, among the original proportionals; a particular account of which may be ſeen in my book of Logarithms above mentioned.

The methods above alluded to, relate to Napier's or the hyperbolical ſyſtem of Logarithms, and indeed are in a manner peculiar to that ſort of them. But in an appendix to the poſthumous work, mention is made of other methods, by which the common Logarithms, agreed upon by him and Briggs, may be conſtructed, and which it appears were written after that agreement. One of theſe methods is as follows: Having aſſumed 0 for the Logarithm of 1, and 1000 &c for the Logarithm of 10; this Logarithm of 10, and the ſucceſſive quotients, are to be divided ten times by 5, by which diviſions there will be obtained theſe other ten Logarithms, namely 2000000000, 400000000, 80000000, 16000000, 3200000, 640000, 128000, 25600, 5120, 1024; then this laſt Logarithm, and its quotients, being divided ten times by 2, will give theſe other ten Logarithms,

viz, 512, 256, 128, 64, 32, 16, 8, 4, 2, 1.

And the numbers anſwering to theſe twenty Logarithms are to be found in this manner, viz, Extract the 5th root of 10 (with ciphers), then the 5th root of that root, and ſo on for ten continual extractions of the 5th root: ſo ſhall theſe ten roots be the natural numbers belonging to the firſt ten Logarithms above found, in dividing continually by 5. Next, out of the laſt 5th root is to be extracted the ſquare root, then the ſquare root of this laſt root, and ſo on for ten ſucceſſive extractions of the ſquare root: ſo ſhall theſe laſt ten roots be the natural numbers correſponding to the Logarithms or quotients ariſing from the

the laſt ten diviſions by the number 2. And from theſe twenty Logarithms, 1, 2, 4, 8, &c, and their natural numbers, the author obſerves that other Logarithms and their numbers may be formed, namely by adding the Logarithms, and multiplying their correſponding numbers. But, beſides the immenſe labour of this method, it is evident that this proceſs would generate rather an antilogarithmic canon, ſuch as Dodſon's, than the table of Briggs.

Napier next mentions another method of deriving a few of the primitive numbers and their Logarithms, namely, by taking continually geometrical means, firſt between 10 and 1, then between 10 and this mean, and again between 10 and the laſt mean, and ſo on; and then taking the arithmetical means between their correſponding Logarithms.

He then lays down various relations between numbers and their Logarithms, ſuch as, that the products and quotients of numbers, anſwer to the ſums and differences of their Logarithms; and that the powers and roots of numbers, anſwer to the products and quotients of the Logarithms when multiplied or divided by the index of the power or root, &c; as alſo that, of any two numbers, whoſe Logarithms are given, if each number be raiſed to the power denoted by the Logarithm of the other, the two reſults will be equal; thus, if x be the Logarithm of any number X, and y the Logarithm of Y, then is $X^y = Y^x$. Napier then adverts to another method of making the Logarithms to a few of the prime integer numbers, which is well adapted to the conſtruction of the common table of Logarithms: this method eaſily follows from what has been ſaid above, and it depends on this property, that the Logarithm of any number in this ſcale, is one leſs than the number of places or figures contained in that power of the given number whoſe exponent is 10000000000, or the Logarithm of 10, at leaſt as to integer numbers, for they really differ by a fraction, as is ſhewn by Mr. Briggs in his illuſtrations of theſe properties; printed at the end of this Appendix to the Conſtruction of Logarithms.

Kepler gave a conſtruction of Logarithms ſomewhat varied from Napier's. His work is divided into two parts: In the firſt, he raiſes a regular and purely mathematical ſyſtem of proportions, and the meaſures of them, demonſtrating both the nature and principles of the conſtruction of Logarithms, which he calls the *meaſures of ratios*: and in the ſecond part, he applies thoſe principles in the actual conſtruction of his table, which contains only 1000 numbers and their Logarithms. The fundamental principles are briefly theſe: That at the beginning of the Logarithms, their increments or differences are equal to thoſe of the natural numbers: that the natural numbers may be conſidered as the decreaſing coſines of increaſing arcs: and that the ſecants of thoſe arcs at the beginning have the ſame differences as the coſines, and therefore the ſame differences as the Logarithms. Then, ſince the ſecants are the reciprocals of the coſines of the ſame arcs, from the foregoing principles, he eſtabliſhes the following method of raiſing the firſt 100 Logarithms, to the numbers 1000, 999, 998, &c, to 900; viz, in this manner: Divide the radius 1000, increaſed with ſeven ciphers, by each of theſe numbers ſeparately, and the quotients will be the ſecants of thoſe arcs which have the diviſors for their coſines; continuing the diviſion to the 8th figure, as it is in that place only that the arithmetical and geometrical means differ. Then by adding continually the arithmetical means between every two ſucceſſive ſecants, the ſums will be the the ſeries of Logarithms. Or by adding continually every two ſecants, the ſucceſſive ſums will be the ſeries of the double Logarithms. He then derives all the other Logarithms from theſe firſt 100, by common principles.

Briggs firſt adverts to the methods mentioned above, in the Appendix to Napier's Conſtruction, which methods were common to both theſe authors, and had doubtleſs been jointly agreed upon by them. He firſt gives an example of computing a Logarithm by the property, that the Logarithm is one leſs than the number of places or figures contained in that power of the given number whoſe exponent is the Logarithm of 10 with ciphers. Briggs next treats of the other general method of finding the Logarithms of prime numbers, which he thinks is an eaſier way than the former, at leaſt when many figures are required. This method conſiſts in taking a great number of continued geometrical means between 1 and the given number whoſe Logarithm is required; that is, firſt extracting the ſquare root of the given number, then the root of the firſt root, the root of the 2d root, the root of the 3d root, and ſo on, till the laſt root ſhall exceed 1 by a very ſmall decimal, greater or leſs according to the intended number of places to be in the Logarithm ſought: then finding the Logarithm of this ſmall number, by eaſy methods deſcribed afterwards, he doubles it as often as he made extractions of the ſquare root, or, which is the ſame thing, he multiplies it by ſuch power of 2 as is denoted by the ſaid number of extractions, and the reſult is the required Logarithm of the given number; as is evident from the nature of Logarithms.

But as the extraction of ſo many roots is a very troubleſome operation, our author deviſes ſome ingenious contrivances to abridge that labour, chiefly by a proper application of the ſeveral orders of the differences of numbers, forming the firſt inſtance of what may called *the differential method*; but for a particular deſcription of theſe methods, ſee my Treatiſe of Logarithms, above quoted, pag. 65 &c.

Mr. James Gregory, in his Vera Circuli Hyperbolæ Quadratura, printed at Padua in 1667, having approximated to the hyperbolic aſymptotic ſpaces by means of a ſeries of inſcribed and circumſcribed polygons, from thence ſhew's how to compute the Logarithms, which are analogous to the areas of thoſe ſpaces: and thus the quadrature of the hyperbolic ſpaces became the ſame thing as the computation of the Logarithms. He here alſo lays down various methods to abridge the computation, with the aſſiſtance of ſome properties of numbers themſelves, by which the Logarithms of all prime numbers under 1000 may be computed, each by one multiplication, two diviſions, and the extraction of the ſquare root. And the ſame ſubject is farther purſued in his Exercitationes Geometricæ. In this latter place, he firſt finds an algebraic expreſſion, in an infinite ſeries, for the Logarithm of $\frac{1+a}{1}$, and then the like for the

Logarithm

Logarithm of $\frac{1}{1-a}$; and as the one ſeries has all its terms poſitive, while thoſe of the other are alternately poſitive and negative, by adding the two together, every 2d term is cancelled, and the double of the other terms gives the Logarithm of the product of

$\frac{1+a}{1}$ and $\frac{1}{1-a}$, or the Logarithm of the $\frac{1+a}{1-a}$, that is of the ratio of $1-a$ to $1+a$: thus, he finds,

first $a - \frac{1}{2}a^2 + \frac{1}{3}a^3 - \frac{1}{4}a^4$ &c $=$ log. of $\frac{1+a}{1}$,

and $a + \frac{1}{2}a^2 + \frac{1}{3}a^3 + \frac{1}{4}a^4$ &c $=$ log. of $\frac{1}{1-a}$,

theref. $2a + \frac{2}{3}a^3 + \frac{2}{5}a^5 + \frac{2}{7}a^7$ &c $=$ l. of $\frac{1+a}{1-a}$,

Which may be accounted Mr. James Gregory's method of making Logarithms.

In 1668, Nicholas Mercator publiſhed his Logarithmotechnia, ſive Methodus Conſtruendi Logarithmos, nova, accurata, & facilis; in which he delivers a new and ingenious method for computing the Logarithms upon principles purely arithmetical; and here, in his modes of thinking and expreſſion, he cloſely follows the celebrated Kepler, in his writings on the ſame ſubject; accounting Logarithms as the meaſures of ratios, or as the number of ratiunculæ contained in the ratio which any number bears to unity. Purely from theſe principles, then, the number of the equal ratiunculæ contained in ſome one ratio, as of 10 to 1, being ſuppoſed given, our author ſhews how the Logarithm, or meaſure, of any other ratio may be found. But this, however, only by-the-bye, as not being the principal method he intends to teach, as his laſt and beſt. Having ſhewn, then, that theſe Logarithms, or numbers of ſmall ratios, or meaſures of ratios, may be all properly repreſented by numbers, and that of 1, or the ratio of equality, the Logarithm or meaſure being always 0, the Logarithm of 10, or the meaſure of the ratio of 10 to 1, is moſt conveniently repreſented by 1 with any number of ciphers; he then proceeds to ſhew how the meaſures of all other ratios may be found from this laſt ſuppoſition: and he explains theſe principles by ſome examples in numbers.

In the latter part of the work, Mercator treats of his other method, given by an infinite ſeries of algebraic terms, which are collected in numbers by common addition only. He here ſquares the hyperbola, and finally finds that the hyperbolic Logarithm of $1+a$, is equal to the infinite ſeries $a - \frac{1}{2}a^2 + \frac{1}{3}a^3 - \frac{1}{4}a^4$ &c; which may be conſidered as Mercator's quadrature of the hyperbola, or his general expreſſion of an hyperbolic Logarithm, in an infinite ſeries.

And this method was farther improved by Dr. Wallis, in the Philoſ. Tranſ. for the year 1668. The celebrated Newton invented alſo the ſame ſeries for the quadrature of the hyperbola, and the conſtruction of Logarithms, and that before the ſame were given by Gregory and Mercator, though unknown to one another, as appears by his letter to Mr. Oldenburg, dated October 24, 1676. The explanation and conſtruction of the Logarithms are alſo farther purſued in his Fluxions, publiſhed in 1736 by Mr. Colſon.

Dr. Halley, in the Philoſ. Tranſ. for the year 1695, gave a very ingenious eſſay on the conſtruction of Logarithms, intitled, "A moſt compendious and facile method for conſtructing the Logarithms, and exemplified and demonſtrated from the nature of numbers, without any regard to the hyperbola, with a ſpeedy method for finding the number from the given Logarithm."

Inſtead of the more ordinary definition of Logarithms, viz, 'numerorum proportionalium æquidifferentes comites,' the learned author adopts this other, 'numeri rationum exponentes,' as better adapted to the principle on which Logarithms are here conſtructed, conſidering them as the number of ratiunculæ contained in the given ratios whoſe Logarithms are in queſtion. In this way he firſt arrives at the Logarithmic ſeries before given by Newton and others, and afterwards, by various combinations and ſections of the ratios, he derives others, converging ſtill faſter than the former. Thus he found the Logarithms of ſeveral ratios, as below, viz, when multiplied by the modulus peculiar to the ſcale of Logarithms,

$q - \frac{1}{2}q^2 + \frac{1}{3}q^3 - \frac{1}{4}q^4$ &c, the Log. of 1 to $1+q$,

$q + \frac{1}{2}q^2 + \frac{1}{3}q^3 + \frac{1}{4}q^4$ &c, the Log. of 1 to $1-q$,

$\frac{x}{a} - \frac{x^2}{2a^2} + \frac{x^3}{3a^3} - \frac{x^4}{4a^4}$ &c, the Log. of a to b, or

$\frac{x}{b} + \frac{x^2}{2b^2} + \frac{x^3}{3b^3} + \frac{x^4}{4b^4}$ &c, the ſame Log. of a to b, or

$\frac{2x}{z} + \frac{2x^3}{3z^3} + \frac{2x^5}{5z^5} + \frac{2x^7}{7z^7}$ &c, the ſame Log. of a to b,

$\frac{x^2}{2z^2} + \frac{x^4}{4z^4} + \frac{x^6}{6z^6} + \frac{x^8}{8z^8}$ &c, the Log. of $\sqrt{ab}$ to $\frac{1}{2}z$, or

$\frac{1}{y^2} + \frac{1}{3y^6} + \frac{1}{5y^{10}} + \frac{1}{7y^{14}}$ &c, the ſame Log. of $\sqrt{ab}$ to $\frac{1}{2}z$;

where a, b, q, are any quantities, and the values of x, y, z, are thus, viz, $x = b - a$, $z = b + a$, $y = ab + \frac{1}{4}z^2$.

Dr. Halley alſo, firſt of any, performed the reverſe of the problem, by aſſigning the number to a given Logarithm; viz,

$\frac{b}{a} = 1 + l + \frac{1}{2}l^2 + \frac{1}{2\cdot3}l^3 + \frac{1}{2\cdot3\cdot4}l^4$ &c, or

$\frac{a}{b} = 1 - l + \frac{1}{2}l^2 - \frac{1}{2\cdot3}l^3 + \frac{1}{2\cdot3\cdot4}l^4$ &c.

where l is the Logarithm of the ratio of a the leſs, to b the greater of any two terms.

Mr. Abraham Sharp of Yorkſhire made many calculations and improvements in Logarithms, &c. The moſt remarkable of theſe were, his quadrature of the circle to 72 places of figures, and his computation of Logarithms to 61 figures, viz, for all numbers to 100, and for all prime numbers to 1100.

The celebrated Mr. Roger Cotes gave to the world a learned tract on the nature and conſtruction of Logarithms: this was firſt printed in the Philoſ. Tranſ. N° 338, and afterwards with his Harmonia Menſurarum in 1722, under the title Logometria. This tract has juſtly been complained of, as very obſcure and intricate, and the principle is ſomething between that of Kepler and the method of Fluxions. He invented the terms Modulus and Modular ratio, this being the ratio

of $1 + \frac{1}{1} + \frac{1}{2} + \frac{1}{2\cdot3} + \frac{1}{2\cdot3\cdot4} + \frac{1}{2\cdot3\cdot4\cdot5}$ &c to 1 or

of 1 to $1 - \frac{1}{1} + \frac{1}{2} - \frac{1}{2\cdot3} + \frac{1}{2\cdot3\cdot4} - \frac{1}{2\cdot3\cdot4\cdot5}$ &c;

&c; that is the ratio of 2·71828182845 9 &c to 1, or the ratio of 1 to 0·36787944117 1 &c; the modulus of any ſyſtem being the meaſure or Logarithm of that ratio, which in the hyp. Logarithms is 1, and in Briggs's or the common Logarithms is 0·43429448190 3 &c.

The learned Dr. Brook Taylor gave another method of computing Logarithms in the Philoſ. Tranſ. No. 352, which is founded on theſe three principles, viz, 1ſt, That the ſum of the Logarithms of any two numbers is the Logarithm of the product of thoſe numbers; 2d, That the Logarithm of 1 is 0, and conſequently that the nearer any number is to 1, the nearer will its Logarithm be to 0; 3d, That the product of two numbers or factors, of which the one is greater and the other leſs than 1, is nearer to 1, than that factor is which is on the ſame ſide of 1 with itſelf; ſo of the two numbers $\frac{1}{2}$ and $\frac{2}{3}$, the product $\frac{2}{3}$ is leſs than 1, but yet nearer to it than $\frac{2}{3}$ is, which is alſo leſs than 1.— And on theſe principles he founds an ingenious, though not very obvious, approximation to the Logarithms of given numbers.

In the Philoſ. Tranſ. a Mr. John Long gave a method of conſtructing Logarithms, by means of a ſmall table, ſomething in the manner of one of Briggs's methods for the ſame purpoſe.

Alſo in the Philoſ. Tranſ. vol. 61, a tract on the conſtruction of Logarithms is given by the ingenious Mr. William Jones. In this method, all numbers are conſidered as ſome certain powers of a conſtant determined root: thus, any number x is conſidered as the z power of any root r, or $x = r^z$ is taken as a general expreſſion for all numbers in terms of the conſtant root r and a variable exponent z. Now the index z being the Logarithm of the number x, therefore to find this Logarithm, is the ſame thing as to find what power of the radix r is equal to the number x.

An elegant tract on Logarithms, as a comment on Dr. Halley's method, was alſo given by Mr. Jones in his Synopſis Palmariorum Matheſeos, publiſhed in the year 1706.

In the year 1742, Mr. James Dodſon publiſhed his Anti-logarithmic Canon, containing all Logarithms under 100,000, and their correſponding natural numbers to eleven places of figures, with all their differences and the proportional parts; the whole arranged in the order contrary to that uſed in the common tables of numbers and Logarithms, the exact Logarithms being here placed firſt, and their correſponding neareſt numbers in the columns oppoſite to them.

And in 1767, Mr. Andrew Reid publiſhed an "Eſſay on Logarithms," in which he ſhews the computation of Logarithms from principles depending on the binomial theorem, and on the nature of the exponents of powers, the Logarithms of numbers being here conſidered as the exponents of the powers of 10. In this way he brings out the uſual ſeries for Logarithms, and exemplifies Dr. Halley's conſtruction of them. But for the particulars of this, and the methods given by the other authors, we muſt refer to the hiſtorical preface to my treatiſe on Logarithms.

Beſides the authors above-mentioned, many others have treated on the ſubject of Logarithms; among the principal of whom are Leibnitz, Euler, Maclaurin, Wolfius, Keill, and profeſſor Simſon in an ingenious geometrical tract on Logarithms, contained in his poſthumous works, elegantly printed at Glaſgow in the year 1776, at the expence of the learned Earl Stanhope, and by his lordſhip diſpoſed of in preſents among gentlemen moſt eminent for mathematical learning.

For the deſcription and uſes of Logarithms in numeral calculations, with the ſhorteſt method of conſtructing them, ſee the Hiſtorical Introduction to my Logarithms, pa. 124 & ſeq.

Briggs's or *Common* LOGARITHMS, are thoſe that have 1 for the Logarithm of 10, or which have 0·43429448190 &c for the modulus; as has been explained above.

Hyperbolic LOGARITHMS, are thoſe that were computed by the inventor Napier, and called alſo ſometimes *Natural Logarithms*, having 1 for their modulus, or 2·30258509299 4 &c for the Logarithm of 10. Theſe have ſince been called Hyperbolical Logarithms, becauſe they are analogous to the areas of a right-angled hyperbola between the aſymptotes and the curve. See LOGARITHMS, alſo HYPERBOLA and ASYMPTOTIC SPACE.

Logiſtic LOGARITHMS, are certain Logarithms of ſexageſimal numbers or fractions, uſeful in aſtronomical calculations. The Logiſtic Logarithm of any number of ſeconds, is the difference between the common Logarithm of that number and the Logarithm of 3600, the ſeconds in 1 degree.

The chief uſe of the table of Logiſtic Logarithms, is for the ready computing a proportional part in minutes and ſeconds, when two terms of the proportion are minutes and ſeconds, or hours and minutes, or other ſuch ſexageſimal numbers. See the Introd. to my Logarithms, pa. 144.

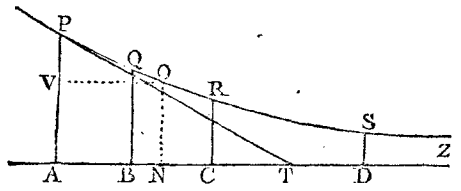
Imaginary LOGARITHM, a term uſed in the Log. of imaginary and negative quantities; ſuch as $-a$, or $\sqrt{-a^2}$ or $a\sqrt{-1}$. The fluents of certain imaginary expreſſions are alſo Imaginary Logarithms; as of $\frac{\dot{x}}{x\sqrt{-1}}$, or of $\frac{a\dot{x}}{cx\sqrt{-1}}$, &c. See Euler Analyſ. Infin. vol. i. pa. 72, 74.

It is well known that the expreſſion $\frac{\dot{x}}{x}$ repreſents the fluxion of the Logarithm of x, and therefore the fluent of $\frac{\dot{x}}{x}$ is the Logarithm of x; and hence the fluent of $\frac{\dot{x}}{x\sqrt{-1}}$ is the Imaginary Logarithm of x.

However, when theſe Imaginary Logarithms occur in the ſolutions of problems, they may be transformed into circular arcs or ſectors; that is, the Imaginary Logarithm, or imaginary hyperbolic ſector, becomes a real circular ſector. See Bernoulli Oper. tom. i, pa. 400, and pa. 512. Maclaurin's Fluxions, art. 762. Cotes's Harmon. Menſ. pa. 45. Walmeſley, Anal. des Meſ. pa. 63.

LOGARITHMIC, or LOGISTIC CURVE, a curve ſo called from its properties and uſes, in explaining and conſtructing the Logarithms, becauſe its ordinates are in geometrical progreſſion, while the abſciſſes are in arithmetical progreſſion; ſo that the abſciſſes are as the Logarithms of the correſponding ordinates. And hence the

the curve will be conſtructed in this manner: Upon any right line, as an axis, take the equal parts AB, BC, CD, &c, or the arithmetical progreſſion AB, AC, AD, &c; and at the points A, B, C, D, &c, erect the perpendicular ordinates AP, BQ, CR, DS, &c, in a geometrical progreſſion; ſo is the curve line drawn through all the points P, Q, R, S, &c, the Logarithmic, or Logiſtic Curve; ſo called, becauſe any abſciſs AB, is as the Logarithm of its ordinate BQ. So that the axis ABC &c is an aſymptote to the curve.



Hence, if any abſciſs AN $= x$, its ordinate NO $= y$, AP $= 1$, and $a =$ a certain conſtant quantity, or the modulus of the Logarithms; then the equation of the curve is $\dot{x} = a \times$ log. of $y =$ log. y^a.

And if the fluxion of this equation be taken, it will be $\dot{x} = \frac{a\dot{y}}{y}$; which gives this proportion,

$$\dot{y} : \dot{x} :: y : a$$

but in any curve $\dot{y} : \dot{x} :: \dot{y}$: the ſubtangent AT; and therefore the ſubtangent of this curve is everywhere equal to the conſtant quantity a, or the modulus of the Logarithms.

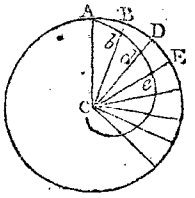
To find the Area contained between two ordinates. Here the fluxion of the area A or $y\dot{x}$ is $y \times \frac{a\dot{y}}{y} = a\dot{y}$; and the correct fluent is $A = a \times \overline{AP - y}$ $= a \times \overline{AP - NO} = a \times PV =$ AT $\times$ PV. That is, the area APON between any two ordinates, is equal to the rectangle of the conſtant ſubtangent and the difference of the ordinates. And hence, when the abſciſs is infinitely long, or the farther ordinate equal to nothing, then the infinitely long area APZ is equal AT $\times$ AP, or double the triangle APT.

For the Solid formed by the curve revolved about its axis AZ. The fluxion of the ſolid is $\dot{s} = py^2\dot{x} = py^2 \times \frac{a\dot{y}}{y} = pay\dot{y}$, where p is $= 3{\cdot}1416$; and the correct fluent is $s = \frac{1}{2}pa \times \overline{AP^2 - y^2} = \frac{1}{2}p \times$ AT $\times \overline{AP^2 - NO^2}$, which is half the difference between two cylinders of the common altitude a or AT, and the radii of their baſes AP, NO. And hence ſuppoſing the ſolid infinitely long towards Z, where y or the ordinate is nothing, the infinitely long ſolid will be equal to $\frac{1}{2}pa \times AP^2 = \frac{1}{2}p \times$ AT $\times AP^2$, or half the cylinder on the ſame baſe and its altitude AT.

It has been ſaid that Gunter gave the firſt idea of a curve whoſe abſciſſes are in arithmetical progreſſion, while the correſponding ordinates are in geometrical progreſſion, or whoſe abſciſs are the Logarithms of their ordinates; but I do not find it noticed in any part of his writings. This curve was afterwards conſidered by others, and named the Logarithmic or Logiſtic Curve by Huygens in his Diſſertatio de Cauſa Gravitatis, where he enumerates all the principal properties of it, ſhewing its analogy to Logarithms. Many other learned men have alſo treated of its properties; particularly Le Seur and Jacquier, in their Comment on Newton's Principia; Dr. John Keill, in the elegant little Tract on Logarithms ſubjoined to his edition of Euclid's Elements; and Francis Maſeres Eſq. Curſitor Baron of the Exchequer, in his ingenious Treatiſe on Trigonometry: ſee alſo Bernoulli's Diſcourſe in the Acta Eruditorum for the year 1696, pa. 216; Guido Grando's Demonſtratio Theorematum Huygeneanorum circa Logiſticam ſeu Logarithmicam Lineam; and Emerſon on Curve Lines, pa. 19.—It is indeed rather extraordinary that this curve was not ſooner announced to the public, ſince it reſults immediately from Napier's manner of conceiving the generation of Logarithms, by only ſuppoſing the lines which repreſent the natural numbers as placed at right angles to that upon which the Logarithms are taken.

This curve greatly facilitates the conception of Logarithms to the imagination, and affords an almoſt intuitive proof of the very important property of their fluxions, or very ſmall increments, namely, that the fluxion of the number is to the fluxion of the Logarithm, as the number is to the ſubtangent; as alſo of this property, that if three numbers be taken very nearly equal, ſo that their ratios may differ but a little from a ratio of equality, as the three numbers 10000000, 10000001, 10000002, their differences will be very nearly proportional to the Logarithms of the ratios of thoſe numbers to each other: all which follows from the Logarithmic arcs being very little different from their chords, when they are taken very ſmall. And the conſtant ſubtangent of this curve is what was afterwards by Cotes called the Modulus of the Syſtem of Logarithms.

LOGARITHMIC, or *Logiſtic, Spiral*, a curve conſtructed as follows. Divide the arch of a circle into any equal parts AB, BD, DE, &c; and upon the radii drawn to the points of diviſion take C*b*, C*d*, C*e*, &c, in a geometrical progreſſion; ſo is the curve *Abde* &c the Logarithmic Spiral; ſo called, becauſe it is evident that AB, AD, AE, &c, being arithmeticals, are as the the Logarithms of CA, C*b*, C*d*, C*e*, &c, which are geometricals; and a Spiral, becauſe it winds continually about the centre C, coming continually nearer, but without ever really falling into it.



In the Philoſ. Tranſ. Dr. Halley has happily applied this curve to the diviſion of the meridian line in Mercator's chart. See alſo Cotes's Harmonia Menſ., Guido Grando's Demonſt. Theor. Huygen., the Acta Erudit. 1691, and Emerſon's Curves, &c.

LOGISTICS, or LOGISTICAL ARITHMETIC, a name ſometimes employed for the arithmetic of ſexageſimal fractions, uſed in aſtronomical computations.

This name was perhaps taken from a Greek treatiſe of Barlæmus, a Monk, who wrote a book of Sexageſimal Multiplication, which he called Logiſtic. Voſſius places this author about the year 1350, but he miſtakes the work for a Treatiſe on Algebra.

The ſame term however has been uſed for the rules

of computations in Algebra, and in other ſpecies of Arithmetic: witneſs the Logiſtics of Vieta and other writers.

Shakerly, in his Tabulæ Britannicæ, has a Table of Logarithms adapted to ſexageſimal fractions, and which he calls Logiſtical Logarithms; and the expeditious arithmetic, obtained by means of them, he calls Logiſtical Arithmetic.

LOGISTICAL *Curve, Line,* or *Spiral,* the ſame as the Logarithmic, which ſee.

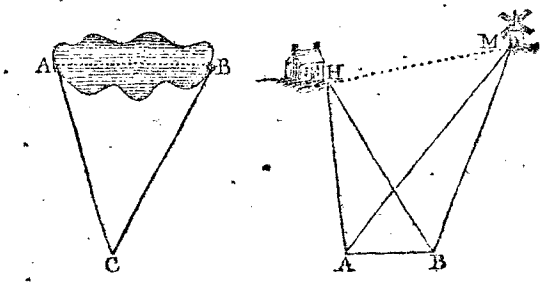
LONG (ROGER), D.D. maſter of Pembroke-hall in Cambridge, Lowndes's profeſſor of aſtronomy in that univerſity, &c, was author of a well-known and much approved treatiſe of aſtronomy, and the inventor of a remarkably curious aſtronomical machine. This was a hollow ſphere, of 18 feet diameter, in which more than 30 perſons might ſit conveniently. Within ſide the ſurface, which repreſented the heavens, was painted the ſtars and conſtellations, with the zodiac, meridians, and axis parallel to the axis of the world, upon which it was eaſily turned round by a winch. He died, December 16, 1770, at 91 years of age.

A few years before his death, Mr. Jones gave ſome anecdotes of Dr. Long, as follows: "He is now in the 88th year of his age, and for his years vegete and active. He was lately put in nomination for the office of vice-chancellor: he executed that truſt once before, I think in the year 1737. He is a very ingenious perſon, and ſometimes very facetious. At the public Commencement, in the year 1713, Dr. Greene (maſter of Bennet college, and afterwards biſhop of Ely) being then vice-chancellor, Mr. Long was pitched upon for the tripos performance; it was witty and humorous, and has paſſed through divers editions. Some that remembered the delivery of it, told me, that in addreſſing the vice-chancellor (whom the univerſity wags uſually ſtyled *Miſs Greene),* the tripos-orator, being a native of Norfolk, and aſſuming the Norfolk dialect, inſtead of ſaying, *Domine Vice-Cancellarie,* archly pronounced the words thus, *Domina Vice-Cancellaria*; which occaſioned a general ſmile in that great auditory. His friend the late Mr. Bonfoy of Ripton told me this little incident: 'That he and Dr. Long walking together in Cambridge in a duſky evening, and coming to a ſhort *poſt* fixed in the pavement, which Mr. Bonfoy in the midſt of chat and inattention, took to be a *boy* ſtanding in his way, he ſaid in a hurry, 'Get out of my way, boy!' '*That boy, Sir,* ſaid the Doctor very calmly and ſilly, *is a* poſt-boy, *who turns out of his way for nobody.*' I could recollect ſeveral other ingenious repartees if there were occaſion. One thing is remarkable, he never was a hale and hearty man, always of a tender and delicate conſtitution, yet took great care of it: his common drink water; he always dines with the Fellows in the Hall Of late years he has left off eating fleſh-meats; in the room thereof, puddings; vegetables, &c; ſometimes a glaſs or two of wine."

LONGIMETRY, the art of meaſuring lengths or diſtances, both acceſſible and inacceſſible, forming a part of what is called Heights and Diſtances, being an application of geometry and trigonometry to ſuch meaſurements.

As to acceſſible lengths, they are eaſily meaſured by the actual application of a rod, a chain, or wheel, or ſome other meaſure of length.

But inacceſſible lengths require the practice and properties of geometry and trigonometry, either in the meaſurement and conſtruction, or in the computation. For example, Suppoſe it were required to know the length or diſtance between the two places A and B, to which places there is free acceſs, but not to the intermediate parts, on account of water or ſome other impediment; meaſure therefore, from A and B, the diſtances to any convenient place C, which ſuppoſe to be thus, viz, AC = 735, and BC = 840 links; and let the angle at C, taken with a theodolite or other inſtrument, be 55° 40′. From theſe meaſures the length or diſtance AB may be determined, either by geometrical meaſurement, or by trigonometrical computation. Thus, firſt, lay down an angle C = 55° 40′, and upon its legs ſet off, from any convenient ſcale of equal parts, CA = 735, and CB = 840; then meaſure the diſtance between the points A and B by the ſame ſcale of equal parts, which will be found to be 740 nearly.



Or this by calculation,

840 180° − 55° 40′ = 124° 20′, its half 62° 10′,
735

Sum 1575	- - -	1·197286
Dif. 105	- - -	0·021189
Tang. 62° 10′	- -	10·277379
Tang. 7° 11′ 11″	-	9·101288
f. Sum or ∠ A = 99° 21′ 11″		9·971109
to f. ∠ C = 55 40		9·916859
So BC = 840		0·924279
To AB = 741·2		0·869940

For a 2d Example—Suppoſe it were required to find the diſtance between two inacceſſible objects, as between the houſe and mill, H and M; firſt meaſure any convenient line on the ground, as AB, 300 yards; then at the ſtation A take the angles BAM = 58° 20′; and MAH = 37°; alſo at the ſtation B take the angles ABH = 53° 30′, and HBM = 45° 15′; from hence the diſtance or length MH may be found, either by geometrical conſtruction, or by trigonometrical calculation, thus:

Firſt draw a line AB of the given length of 300, by a convenient ſcale of equal parts; then at the point A lay down the angles BAM and MAH of the magnitudes

nitudes above given; and alſo at the point B the given angles ABH and HBM: then by applying the length HM to the ſame ſcale of equal parts, it is found to be nearly 480 yards.

Otherwiſe, by calculation. Firſt, by adding and ſubtracting the angles, there is found as below:

	37°	00′	58°	20′	53°	30′	
	58	20	53	30	45	15

the dif. of which is AMH = 35 46.

Laſtly,

as ſ. AMH : ſ. MAH :: AH : HM = 479·7933,

the diſtance ſought.

LONGITUDE *of the Earth*, is ſometimes uſed to denote its extent from weſt to eaſt, according to the direction of the equator. By which it ſtands contradiſtinguiſhed from the Latitude of the earth, which denotes its extent from one pole to the other.

LONGITUDE *of a Place*, in Geography, is its longitudinal diſtance from ſome firſt meridian, or an arch of the equator intercepted between the meridian of that place and the firſt meridian.

LONGITUDE *in the Heavens*, as of a ſtar, &c, is an arch of the ecliptic, counted from the beginning of Aries, to the place where it is cut by a circle perpendicular to it, and paſſing through the place of the ſtar.

LONGITUDE *of the Sun or Star from the next equinoctial point*, is the degrees they are diſtant from the beginning of Aries or Libra, either before or after them; which can never exceed 180 degrees.

LONGITUDE, *Geocentric*, *Heliocentric*, &c, the Longitude of a planet as ſeen from the earth, or from the ſun. See the reſpective terms.

LONGITUDE, *in Navigation*, is the diſtance of a ſhip, or place, eaſt or weſt, from ſome other place or meridian, counted in degrees of the equator. When this diſtance is counted in leagues, or miles, or in degrees of the meridian, and not in thoſe proper to the parallel of Latitude, it is uſually called Departure.

An eaſy practicable method of finding the Longitude at ſea, is the only thing wanted to render the Art of Navigation perfect, and is a problem that has greatly perplexed mathematicians for the laſt two centuries: accordingly moſt of the commercial nations of Europe have offered great rewards for the diſcovery of it; and in conſequence very conſiderable advances have been made towards a perfect ſolution of the problem, eſpecially by the Engliſh.

In the year 1598, the government of Spain offered a reward of 1000 crowns for the ſolution of this problem; and ſoon after the States of Holland offered 10 thouſand florins for the ſame. Encouraged by ſuch offers, in 1635, M. John Morin, profeſſor of mathematics at Paris, propoſed to cardinal Richlieu, a method of reſolving it; and though the commiſſioners, who were appointed to examine this method, on account of the imperfect ſtate of the lunar tables, judged it inſufficient, cardinal Mazarin, in 1645, procured for the author a penſion of 2000 livres.

In 1714 an act was paſſed in the Britiſh parliament, allowing 2000l. towards making experiments; and alſo offering a reward to the perſon who ſhould diſcover the Longitude at ſea, proportioned to the degree of accuracy that might be attained by ſuch diſcovery; viz, a reward of 10,000l. if it determines the Longitude to one degree of a great circle, or 60 geographical miles; 15,000l. if it determines the ſame to two-thirds of that diſtance; and 20,000l. if it determines it to half that diſtance; with other regulations and encouragements. 12 Ann. cap. 15. See alſo ſtat. 14 Geo. II, cap. 39, and 26 Geo. II, cap. 25. But, by ſtat. Geo. III, all former acts concerning the Longitude at ſea are repealed, except ſo much of them as relates to the appointment and authority of the commiſſioners, and ſuch clauſes as relate to the publiſhing of nautical almanacs, and other uſeful tables; and it enacts, that any perſon who ſhall diſcover a method for finding the Longitude by means of a time-keeper, the principles of which have not hitherto been made public, ſhall be entitled to the reward of 5000l. if it ſhall enable a ſhip to keep her Longitude, during a voyage of 6 months, within 60 geographical miles, or one degree of a great circle; to 7500l. if within 40 geographical miles, or two-thirds of a degree of a great circle; or to a reward of 10,000l. if within 30 geographical miles, or half a degree of a great circle. But if the method ſhall be by means of improved ſolar and lunar tables, the author of them ſhall be entitled to a reward of 5000l. if they ſhew the diſtance of the moon from the ſun and ſtars within 15″ of a degree, anſwering to about 7′ of Longitude, after making an allowance of half a degree for the errors of obſervation, and after compariſon with aſtronomical obſervations for a period of 18½ years, or during the period of the irregularities of the lunar motions. Or that in caſe any other method ſhall be propoſed for finding the Longitude at ſea, beſides thoſe before-mentioned, the author ſhall be entitled to 5000l. if it ſhall determine the Longitude within one degree of a great circle, or 60 geographical miles; to 7500l. if within two-thirds of that diſtance; and to 10,000l. if within half the ſaid diſtance.

Accordingly, many attempts have been made for ſuch diſcovery, and ſeveral ways propoſed, with various degrees of ſucceſs. Theſe however have been chiefly directed to methods of determining the difference of time between any two points on the earth; for the Longitude of any place being an arch of the equator intercepted between two meridians, and this arc being proportional to the time required by the ſun to move from the one meridian to the other, at the rate of 4 minutes of time to one degree of the arch, it follows that the difference of time being known, and turned

into

into degrees according to that proportion, it will give the Longitude.

This meaſurement of time has been attempted by ſome perſons by means of clocks, watches, and other automata: for if a clock or watch were contrived to go uniformly at all ſeaſons, and in all places and ſituations; ſuch a machine being regulated, for inſtance, to London or Greenwich time, would always ſhew the time of the day at London or Greenwich, wherever it ſhould be carried to; then the time of the day at this place being found by obſervations, the difference between theſe two times would give the difference of Longitude, according to the proportion of one degree to 4 minutes of time.

Gemma Friſius, in his tract De Principiis Aſtronomiæ et Geographiæ, printed at Antwerp in 1530, it ſeems firſt ſuggeſted the method of finding the Longitude at ſea by means of watches, or time-keepers; which machines, he ſays, were then but lately invented. And ſoon after, the ſame was attempted by Metius, and ſome others; but the ſtate of watch-making was then too imperfect for that purpoſe. Dr. Hooke and Mr. Huygens alſo, about the year 1664, applied the invention of the pendulum-ſpring to watches; and employed it for the purpoſe of diſcovering the Longitude at ſea. Some diſputes however between Dr. Hooke and the Engliſh Miniſtry prevented any experiments from being made with watches conſtructed by him; but many experiments were made with ſome conſtructed by Huygens; particularly Major Holmes, in a voyage from the coaſt of Guinea in 1665, by one of theſe watches predicted the Longitude of the iſland of Fuego to a great degree of accuracy. This ſucceſs encouraged Huygens to improve the ſtructure of his watches, (ſee Philoſ. Tranſ. for May 1669); but experience ſoon convinced him, that unleſs methods could be diſcovered for preſerving the regular motion of ſuch machines, and preventing the effects of heat and cold, and other diſturbing cauſes, they could never anſwer the intention of diſcovering the Longitude, and on this account his attempts failed.

The firſt perſon who turned his thoughts this way, after the public encouragement held out by the act of 1714, was Henry Sully, an Engliſhman; who, in the ſame year, printed at Vienna, a ſmall tract on the ſubject of watch-making; and afterwards removing to Paris, he employed himſelf there in improving time-keepers for the diſcovery of the Longitude. It is ſaid he greatly diminiſhed the friction in the machine, and rendered uniform that which remained: and to him is principally to be attributed what is yet known of watch-making in France: for the celebrated Julien le Roy was his pupil, and to him owed moſt of his inventions, which he afterwards perfected and executed: and this gentleman, with his ſon, and M. Berthoud, are the principal perſons in France who have turned their thoughts this way ſince the time of Sully. Several watches made by theſe laſt two artiſts, have been tried at ſea, it is ſaid with good ſucceſs, and large accounts have been publiſhed of theſe trials.

In the year 1726 our countryman, Mr. John Harriſon, produced a time-keeper of his own conſtruction, which did not err above one ſecond in a month, for 10 years together: and in the year 1736 he had a machine tried in a voyage to and from Liſbon; which was the means of correcting an error of almoſt a degree and a half in the computation of the ſhip's reckoning. In conſequence of this ſucceſs, Mr. Harriſon received public encouragement to proceed, and he made three other time-keepers, each more accurate than the former, which were finiſhed ſucceſſively in the years 1739, 1758, and 1761; the laſt of which proved ſo much to his own ſatisfaction, that he applied to the commiſſioners of the Longitude to have this inſtrument tried in a voyage to ſome port in the Weſt Indies, according to the directions of the ſtatute of the 12th of Anne above cited. Accordingly, Mr. William Harriſon, ſon of the inventor, embarked in November 1761, on a voyage for Jamaica, with this 4th time-keeper or watch; and on his arrival there, the Longitude, as ſhewn by the time-keeper, differed but one geographical mile and a quarter from the true Longitude, deduced from aſtronomical obſervations. The ſame gentleman returned to England, with the time-keeper, in March 1762; when he found that it had erred, in the 4 months, no more than $1' 54''\frac{1}{2}$ in time, or $28\frac{5}{8}$ minutes of Longitude; whereas the act requires no greater exactneſs than 30 geographical miles, or minutes of a great circle, in ſuch a voyage. Mr. Harriſon now claimed the whole reward of 20,000l, offered by the ſaid act: but ſome doubts ariſing in the minds of the commiſſioners, concerning the true ſituation of the iſland of Jamaica, and the manner in which the time at that place had been found, as well as at Portſmouth; and it being farther ſuggeſted by ſome, that although the time-keeper happened to be right at Jamaica, and after its return to England, it was by no means a proof that it had been always ſo in the intermediate times; another trial was therefore propoſed, in a voyage to the iſland of Barbadoes, in which precautions were taken to obviate as many of theſe objections as poſſible. Accordingly, the commiſſioners previouſly ſent out proper perſons to make aſtronomical obſervations at that iſland, which, when compared with other correſponding ones made in England, would determine, beyond a doubt, its true ſituation: and Mr. William Harriſon again ſet out with his father's time-keeper, in March 1764, the watch having been compared with equal altitudes at Portſmouth, before he ſet out, and he arrived at Barbadoes about the middle of May; where, on comparing it again by equal altitudes of the ſun, it was found to ſhew the difference of Longitude, between Portſmouth and Barbadoes, to be $3^h\ 55^m\ 3^s$; the true difference of Longitude between theſe places, by aſtronomical obſervations, being $3^h\ 54^m\ 20^s$; ſo that the error of the watch was 43^s, or $10'\ 45''$ of Longitude. In conſequence of this, and the former trials, Mr. Harriſon received one moiety of the reward offered by the 12th of Queen Anne, after explaining the principles on which his watch was conſtructed, and delivering this as well as the three former to the Commiſſioners of the Longitude, for the uſe of the public: and he was promiſed the other moiety of the reward, when other time-keepers ſhould be made, on the ſame principles, either by himſelf or others, performing equally well with that which he had laſt made. In the mean time, this laſt time-keeper was ſent down to the Royal Obſervatory at Greenwich, to be tried there under the direction of the Rev. Dr. Maſkelyne, the Aſtronomer Royal. But it did

did not appear, during this trial, that the watch went with the regularity that was expected; from which it was apprehended, that the performance even of the ſame watch, was not at all times equal; and conſequently that little certainty could be expected in the performance of different ones. Moreover, the watch was now found to go faſter than during the voyage to and from Barbadoes, by 18 or 19 ſeconds in 24 hours: but this circumſtance was accounted for by Mr. Harriſon; who informs us that he had altered the rate of its going by trying ſome experiments, which he had not time to finiſh before he was ordered to deliver up the watch to the Board. Soon after this trial, the Commiſſioners of Longitude agreed with Mr. Kendal, one of the watch-makers appointed by them to receive Mr. Harriſon's diſcoveries, to make another watch on the ſame conſtruction with this, to determine whether ſuch watches could be made from the account which Mr. Harriſon had given, by other perſons, as well as himſelf. The event proved the affirmative; for the watch produced by Mr. Kendal, in conſequence of this agreement, went conſiderably better than Mr. Harriſon's did. Mr. Kendal's watch was ſent out with Capt. Cook, in his 2d voyage towards the ſouth pole and round the globe, in the year 1772, 1773, 1774, and 1775; when the only fault found in the watch was, that its rate of going was continually accelerated; though in this trial, of 3 years and a half, it never amounted to $14''\frac{1}{2}$ a day. The conſequence was, that the Houſe of Commons in 1774, to whom an appeal had been made, were pleaſed to order the 2d moiety of the reward to be given to Mr. Harriſon, and to paſs the act above mentioned. Mr. Harriſon had alſo at different times received ſome other ſums of money, as encouragements to him to continue his endeavours, from the Board of Longitude, and from the India Company, as well as from many individuals. Mr. Arnold and ſome other perſons have ſince alſo made ſeveral very good watches for the ſame purpoſe.

Others have propoſed various aſtronomical methods for finding the Longitude. Theſe methods chiefly depend on having an ephemeris or almanac ſuited to the meridian of ſome place, as Greenwich for inſtance, to which the Nautical Almanac is adapted, which ſhall contain for every day computations of the times of all remarkable celeſtial motions and appearances, as adapted to that meridian. So that, if the hour and minute be known when any of the ſame phenomena are obſerved in any other place, whoſe Longitude is deſired, the difference between this time and that to which the time of the ſaid phenomenon was calculated and ſet down in the almanac, will be known, and conſequently the difference of Longitude alſo becomes known, between that place and Greenwich, allowing at the rate of 15 degrees to an hour.

Now it is eaſy to find the time at any place, by means of the altitude or azimuth of the ſun or ſtars; which time it is neceſſary to find by ſuch means, both in theſe aſtronomical modes of determining the Longitude, and in the former by a time-keeper; and it is the difference between that time, ſo determined, and the time at Greenwich, known either by the time-keeper or by the aſtronomical obſervations of celeſtial phenomena, which gives the difference of Longitude, at the rate above-mentioned. Now the difficulty in theſe methods lies in the fewneſs of proper phenomena, capable of being thus obſerved; for all ſlow motions, ſuch as belong to the planet Saturn for inſtance, are quite excluded, as affording too ſmall a difference, in a conſiderable ſpace of time, to be properly obſerved; and it appears that there are no phenomena in the heavens proper for this purpoſe, except the eclipſes or motions of Jupiter's ſatellites, and the eclipſes or motions of the moon, viz, ſuch as her diſtance from the ſun or certain fixed ſtars lying near her path, or her Longitude or place in the zodiac, &c. Now of theſe methods,

1ſt, That by the eclipſes of the moon is very eaſy, and ſufficiently accurate, if they did but happen often, as every night. For at the moment when the beginning, or middle, or end of an eclipſe is obſerved by a teleſcope, there is no more to be done but to determine the time by obſerving the altitude or azimuth of ſome known ſtar; which time being compared with that in the tables, ſet down for the happening of the ſame phenomenon at Greenwich, gives the difference in time, and conſequently of Longitude ſought. But as the beginning or end of an eclipſe of the moon cannot generally be obſerved nearer than one minute, and ſometimes 2 or 3 minutes of time, the Longitude cannot certainly be determined by this method, from a ſingle obſervation, nearer than one degree of Longitude. However, by two or more obſervations, as of the beginning and end &c, a much greater degree of exactneſs may be attained.

2d, The moon's place in the zodiac is a phenomenon more frequent than that of her eclipſes; but then the obſervation of it is difficult, and the calculus perplexed and intricate, by reaſon of two parallaxes; ſo that it is hardly practicable, to any tolerable degree of accuracy.

3d, But the moon's diſtances from the ſun, or certain fixed ſtars, are phenomena to be obſerved many times in almoſt every night, and afford a good practical method of determining the Longitude of a ſhip at almoſt any time; either by computing, from thence, the moon's true place, to compare with the ſame in the almanac; or by comparing her obſerved diſtance itſelf with the ſame as there ſet down.

It is ſaid that the firſt perſon who recommended the finding the Longitude from this obſerved diſtance between the moon and ſome ſtar, was John Werner, of Nuremberg, who printed his annotations on the firſt book of Ptolomy's Geography in 1514. And the ſame thing was recommended in 1524, by Peter Apian, profeſſor of mathematics at Ingolſtadt; alſo about 1530, by Oronce Finé, of Briançon; and the ſame year by the celebrated Kepler, and by Gemma Friſius, at Antwerp; and in 1560, by Nonius or Pedro Nunez.

Nor were the Engliſh mathematicians behind hand on this head. In 1665 Sir Jonas Moore prevailed on king Charles the 2d to erect the Royal Obſervatory at Greenwich, and to appoint Mr. Flamſteed his aſtronomical obſerver, with this expreſs command, that he ſhould apply himſelf with the utmoſt care and diligence to the rectifying the table of the motions of the heavens, and the places of the fixed ſtars, in order to find out the ſo much deſired Longitude at ſea, for perfecting the Art of Navigation. And to the fidelity and induſtry with

with which Mr. Flamſteed executed his commiſſion, it is that we are chiefly indebted for that curious theory of the moon, which was afterwards formed by the immortal Newton. This incomparable philoſopher made the beſt poſſible uſe of the obſervations with which he was furniſhed; but as theſe were interrupted and imperfect, his theory would ſometimes differ from the heavens by 5 minutes or more.

Dr. Halley beſtowed much time on the ſame object; and a Starry Zodiac was publiſhed under his direction, containing all the ſtars to which the moon's appulſe can be obſerved; but for want of correct tables, and proper inſtruments, he could not proceed in making the neceſſary obſervations. In a paper on this ſubject, in the Philoſ. Tranſ. number 421, he expreſſes his hope, that the inſtrument juſt invented by Mr. Hadley might be applied to taking angles at ſea with the deſired accuracy. This great aſtronomer, and after him the Abbé de la Caille, and others, have reckoned the beſt aſtronomical method for finding the Longitude at ſea, to be that in which the diſtance of the moon from the ſun or from a ſtar is uſed; for the moon's daily motion being about 13 degrees, her hourly mean motion is above half a degree, or one minute of a degree in two minutes of time; ſo that an error of one minute of a degree in poſition will produce an error of 2 minutes in time, or half a degree in Longitude. Now from the great improvements made by Newton in the theory of the moon, and more lately by Euler and others on his principles, profeſſor Mayer, of Gottengen, was enabled to calculate lunar tables more correct than any former ones; having ſo far ſucceeded as to give the moon's place within one minute of the truth, as has been proved by a compariſon of the tables with the obſervations made at the Greenwich obſervatory by the late Dr. Bradley, and by Dr. Maſkeline, the preſent Aſtronomer Royal; and the ſame have been ſtill farther improved under his direction, by the late Mr. Charles Maſon, by ſeveral new equations, and the whole computed to tenths of a ſecond. Theſe new tables, when compared with the above-mentioned ſeries of obſervations, a proper allowance being made for the unavoidable error of obſervation, ſeem to give always the moon's Longitude in the heavens correctly within 30 ſeconds of a degree; which greateſt error, added to a poſſible error of one minute in taking the moon's diſtance from the ſun or a ſtar at ſea, will at a medium only produce an error of 42 minutes of Longitude. To facilitate the uſe of the tables, Dr. Maſkelyne propoſed a nautical ephemeris, the ſcheme of which was adopted by the Commiſſioners of Longitude, and firſt executed in the year 1767, ſince which time it has been regularly continued, and publiſhed as far as for the year 1800. But as the rules that were given in the appendix to one of thoſe publications, for correcting the effects of refraction and parallax, were thought too difficult for general uſe, they have been reduced to tables. So that, by the help of the ephemeris, theſe tables, and others that are alſo provided by the Board of Longitude, the calculations relating to the Longitude, which could not be performed by the moſt expert mathematician in leſs than four hours, may now be completed with great eaſe and accuracy in half an hour.

As this method of determining the Longitude depends on the uſe of the tables annually publiſhed for this purpoſe, thoſe who wiſh for farther information are referred to the inſtructions that accompany them, and particularly to thoſe that are annexed to the *Tables requiſite to be uſed with the Aſtronomical and Nautical Ephemeris*, 2d edit. 1781.

4th. The phenomena of Jupiter's ſatellites have commonly been preferred to thoſe of the moon, for finding the Longitude; becauſe they are leſs liable to parallaxes than theſe are, and beſides they afford a very commodious obſervation whenever the planet is above the horizon. Their motion is very ſwift, and muſt be calculated for every hour. Theſe ſatellites of Jupiter were no ſooner announced by Galileo, in his Syderius Nuncius, firſt printed at Venice in 1610, than the frequency of their eclipſes recommended them for this purpoſe; and among thoſe who treated on this ſubject, none was more ſucceſsful than Caſſini. This great aſtronomer publiſhed, at Bologna, in 1688, tables for calculating the appearances of their eclipſes, with directions for finding the Longitudes of places by them; and being invited to France by Louis the 14th, he there, in the year 1693, publiſhed more correct tables of the ſame. But the mutual attractions of the ſatellites rendering their motions very irregular, thoſe tables ſoon became uſeleſs for this purpoſe; inſomuch that they require to be renewed from time to time; a ſervice which has been performed by ſeveral ingenious aſtronomers, as Dr. Pound, Dr. Bradley, M. Caſſini the ſon, and more eſpecially by Mr. Wargentin, whoſe tables are much eſteemed, which have been publiſhed in ſeveral places, as alſo in the Nautical Almanacs for 1771 and 1779.

Now, to find the Longitude by theſe ſatellites; with a good teleſcope obſerve ſome of their phenomena, as the conjunction of two of them, or of one of them with Jupiter, &c; and at the ſame time find the hour and minute, from the altitudes of the ſtars, or by means of a clock or watch, previouſly regulated for the place of obſervation; then, conſulting tables of the ſatellites, obſerve the time when the ſame appearance happens in the meridian of the place for which the tables are calculated; and the difference of time, as before, will give the Longitude.

The eclipſes of the firſt and ſecond of Jupiter's ſatellites are the moſt proper for this purpoſe; and as they happen almoſt daily, they afford a ready means of determining the Longitude of places at land, having indeed contributed much to the modern improvements in geography; and if it were poſſible to obſerve them with proper teleſcopes, in a ſhip under ſail, they would be of great ſervice in aſcertaining its Longitude from time to time. To obviate the inconvenience to which theſe obſervations are liable from the motions of the ſhip, a Mr. Irwin invented what he called a marine chair; this was tried by Dr. Maſkelyne, in his voyage to Barbadoes, when it was not found that any benefit could be derived from the uſe of it. And indeed, conſidering the great power requiſite in a teleſcope proper for theſe obſervations, and the violence, as well as irregularities in the motion of a ſhip, it is to be feared that the complete management of a teleſcope on ſhip-board, will always remain among the deſiderata in this part of nautical ſcience. And farther, ſince all methods that depend on the phenomena of the heavens have alſo this other defect, that they cannot be obſerved at all times, this renders

renders the improvement of time-keepers an object of the greater importance.

Many other ſchemes and propoſals have been made by different perſons, but moſt of them of very little or no uſe; ſuch as by the ſpace between the flaſh and report of a great gun, propoſed by Meſſrs. Whiſton and Ditton; and another propoſed by Mr. Whiſton, by means of the inclinatory or dipping needle; beſides a method by the variation of the magnetic needle, &c, &c.

LONGITUDE *of Motion*, is a term uſed by Dr. Wallis for the meaſure of motion, eſtimated according to its line of direction; or it is the diſtance or length gone through by the centre of any moving body, as it moves on in a right line.

The ſame author calls the meaſure of any motion, eſtimated according to the line of direction of the vis motrix, the *Altitude* of it.

LONGOMONTANUS (CHRISTIAN), a learned aſtronomer, born in Denmark in 1562, in the village of Longomontum, whence he took his name. Voſſius, by miſtake, calls him Chriſtopher. Being the ſon of a poor man, a plowman, he was obliged to ſuffer, during his ſtudies, all the hardſhips to which he could be expoſed, dividing his time, like the philoſopher Cleanthes, between the cultivation of the earth and the leſſons he received from the miniſter of the place. At length, at 15 years old, he ſtole away from his family, and went to Wiburg, where there was a college, in which he ſpent 11 years; and though he was obliged to earn his livelihood as he could, his cloſe application to ſtudy enabled him to make a great progreſs in learning, particularly in the mathematical ſciences.

From hence he went to Copenhagen; where the profeſſors of that univerſity ſoon conceived a very high opinion of him, and recommended him to the celebrated Tycho Brahe; with whom Longomontanus lived 8 years, and was of great ſervice to him in his obſervations and calculations. At length, being very deſirous of obtaining a profeſſor's chair in Denmark, Tycho Brahe conſented, with ſome difficulty, to his leaving him; giving him a diſcharge filled with the higheſt teſtimonies of his eſteem, and furniſhing him with money for the expence of his long journey from Germany, whither Tycho had retired.

He accordingly obtained a profeſſorſhip of mathematics in the univerſity of Copenhagen in 1605; the duty of which he diſcharged very worthily till his death, which happened in 1647, at 85 years of age.

Longomontanus was author of ſeveral works, which ſhew great talents in mathematics and aſtronomy. The moſt diſtinguiſhed of them, is his *Aſtronomica Danica*, firſt printed in 4to, 1621, and afterwards in folio in 1640, with augmentations. He amuſed himſelf with endeavouring to ſquare the circle, and pretended that he had made the diſcovery of it; but our countryman Dr. John Pell attacked him warmly on that ſubject, and proved that he was miſtaken.——It is remarkable that, obſcure as his village and father were, he contrived to dignify and eternize them both; for he took his name from his village, and in the title page to ſome of his works he wrote himſelf *Chriſtianus Longomontanus Severini filius*, his father's name being Severin or Severinus.

LOXODROMIC CURVE, or SPIRAL, is the ſame as the Rhumb line, or path of a ſhip ſailing always on the ſame courſe in an oblique direction, or making always the ſame angle with every meridian. It is a ſpecies of logarithmic ſpiral, deſcribed on the ſurface of the ſphere, having the meridians for its radii.

LOXODROMICS, the art or method of oblique ſailing, by the loxodromic or rhumb line.

LOZENGE, an oblique-angled parallelogram; being otherwiſe called a rhombus, or a rhomboides.

LUBIENIETSKI (STANISLAUS), a Poliſh gentleman, born at Cracow, in 1623, and educated with great care by his father. He was learned in aſtronomy, and became a celebrated Socinian miniſter. He took great pains to obtain a toleration from the German princes for his Socinian brethren. His endeavours however were all in vain; being himſelf perſecuted by the Lutheran miniſters, and baniſhed from place to place; till at length he was baniſhed out of the world, with his two daughters, by poiſon, in 1675, his wife narrowly eſcaping.

We have, of his writing, *A Hiſtory of the Reformation in Poland*; and a Treatiſe on Comets, intitled *Theatrum Cometicum*, printed at Amſterdam in 2 volumes folio; which is a moſt elaborate work, containing a minute hiſtorical account of every ſingle comet that had been ſeen or recorded.

LUCIDA CORONÆ, a fixed ſtar of the 2d magnitude, in the northern crown. See CORONA *Borealis*.

LUCIDA HYDRÆ. See COR *Hydræ*.

LUCIDA LYRÆ, a bright ſtar of the firſt magnitude in the conſtellation Lyra.

LUCIFER, a name given to the planet Venus, when ſhe appears in the morning before ſunriſe.

LUMINARIES, a term uſed for the ſun and moon, by way of eminence, for their extraordinary luſtre, and the great quantity of light they give us.

LUNA, the Moon; which ſee.

LUNAR, ſomething relating to the moon.

LUNAR *Cycle*, or *Cycle of the Moon*. See CYCLE.

LUNAR *Method for the Longitude*, a method of keeping or finding the Longitude by means of the moon's motions, particularly by her obſerved diſtances from the ſun and ſtars; for which, ſee the article LONGITUDE.

LUNAR *Month*, is either Periodical, Synodical, or Illuminative. Which ſee; alſo MONTH.

LUNAR *Year*, conſiſts of 354 days, or 12 ſynodical months, of 29½ days each. See YEAR.

In the early ages, the lunar year was uſed by all nations; the variety of courſe being more frequent and conſpicuous in this planet, and conſequently better known to men, than thoſe of any other. The Romans regulated their year, in part, by the moon, even till the time of Julius Cæſar. The Jews too had their lunar month and year.

LUNAR *Dial*, *Eclipſe*, *Horoſcope*, and *Rainbow*. See the ſeveral ſubſtantives.

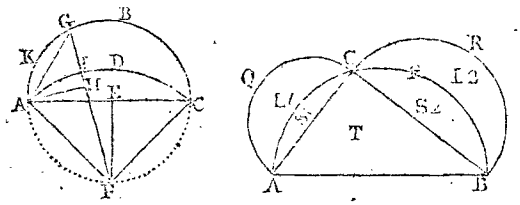
LUNATION, the period or time between one new moon and another; it is alſo called the ſynodical month, conſiſting of 29 days 12 hrs. 44m. 3 ſec. 11 thirds; exceeding the periodical month by 2 ds. 5 hrs. 0 m. 55 ſec.

LUNE, or LUNULA, or little moon, is a geometri-

cal figure, in form of a crescent, terminated by the arcs of two circles that intersect each other within.

Though the quadrature of the whole circle has never been effected, yet many of its parts have been squared. The first of these partial quadratures was that of the Lunula, given by Hippocrates of Scio, or Chios; who, from being a shipwrecked merchant, commenced geometrician. But although the quadrature of the Lune be generally ascribed to Hippocrates, yet Proclus expressly says it was found out by Oenopidas of the same place. See Heinius in Mem. de l'Acad. de Berlin, tom. ii. pa. 410, where he gives a dissertation concerning this Oenopidas. See also CIRCLE, and QUADRATURE.

The Lune of Hippocrates is this: Let ABC be a semicircle, having its centre E, and ADC a quadrant, having its centre F; then the Figure ABCDA, contained between the arcs of the semicircle and quadrant, is his Lune; and it is equal to the right-angled triangle ACF, as is thus easily proved. Since $AF^2 = 2AE^2$, that is, the square of the radius of the quadrant equal to double the square of the radius of the semicircle; therefore the quadrantal area ADCFA is = the semicircle ABCEA; from each of these take away the common space ADCEA, and there remains the triangle ACF = the Lune ABCDA.



Another property of this Lune, which is the more general one of the former, is, that if FG be any line drawn from the point F, and AH perpendicular to it; then is the intercepted part of the Lune AGIA = the triangle AGH cut off by the chord line AG; or in general, that the small segment AKGA is equal to the trilineal AIHA. For, the angle AFG being at the centre of the one circle, and at the circumference of the other, the arcs cut off AG, AI are similar to the wholes ABC, ADC, therefore the small seg. AKGA is to the semisegment AIH, as the whole semicircle ABCA to the semisegment or quadrant ADCF, that is in a ratio of equality.

Again, if ABC (fig. 2) be a triangle, right angled at C, and if semicircles be described on the three sides as diameters; then the triangle T (ABC) is equal to the sum of the two Lunes L1, L2. For, the greatest semicircle is equal to the sum of both the other two; from the greatest semicircle take away the segments S1 and S2, and there remains the triangle T; also from the two less semicircles take away the same two segments S1 and S2, and there remains the two Lunes L1 and L2; therefore the triangle T = L1 + L2 the two Lunes.

LUNETTE, in Fortification, an inveloped counterguard, or mound of earth, made beyond the second ditch, opposite to the place of arms; differing from the ravelins only in their situation. Lunettes are usually made in wet ditches, and serve the same purpose as fausse-brays, to defend the passage of the ditch.

LUPUS, the *Wolf*, a southern constellation, joined to the Centaur, containing together 19 stars in Ptolomy's catalogue, but 24 in the Britannic catalogue.

LYNX, a constellation of the northern hemisphere, composed by Hevelius out of the unformed stars. In his catalogue it consists of 19 stars, but in the Britannic 44.

LYONS (ISRAEL), a good mathematician and botanist, was the son of a Polish Jew silversmith, and teacher of Hebrew at Cambridge in England, where he was come to settle, and where young Lyons was born, 1739. He was a very extraordinary young man for parts and ingenuity; and shewed very early in life a great inclination to learning, particularly mathematics, on which account he was much patronized by Dr. Smith, master of Trinity college. About 1755 he began to study botany, which he continued occasionally till his death; in which he made a considerable progress, and could remember not only the Linnæan names of almost all the English plants, but even the synonyma of the old botanists; and he had prepared large materials for a *Flora Cantabrigiensis*, describing fully every part of each plant from the specimen, without being obliged to consult, or being liable to be misled by, former authors.

In 1758, he obtained much celebrity by publishing *A Treatise on Fluxions*, dedicated to his patron, Dr. Smith; and in 1763, *Fasciculus Plantarum circa Cantabrigiam, &c.* In the same year, or the year before, he read Lectures on Botany at Oxford with great applause, to at least 60 pupils; but he could not be prevailed on to make a long absence from Cambridge.

Mr. Lyons was some time employed as one of the computers of the Nautical Almanac; and besides he received frequent other presents from the Board of Longitude for his own inventions.——He had studied the English history; and could quote whole passages from the Monkish writers verbatim. He could read Latin and French with ease, but wrote the former ill. He was appointed by the Board of Longitude to sail with Capt. Phipps, in his voyage towards the North Pole, in 1773, as astronomical observator; and he discharged that office to the satisfaction of his employers. After his return from this voyage, he married, and settled in London, where he died of the meazles in about two years.

At the time of his death he was engaged in preparing for the press, a complete edition of all the works of the late learned Dr. Halley; a work very much wanted. —His *Calculations in Spherical Trigonometry abridged*, were printed in the Philos. Transf. vol. 65, for the year 1775, pa. 470.—After his death, his name appeared in the title-page of *A Geographical Dictionary*, the astronomical parts of which were said to be "taken from the papers of the late Mr. Israel Lyons of Cambridge, author of several valuable mathematical productions, and astronomer in lord Mulgrave's voyage to the northern hemisphere."—The astronomical and other mathematical calculations, printed in the account of captain Phipps's voyage towards the north pole, mentioned above, were made by Mr. Lyons. This appeared afterwards, by the acknowledgment of captain Phipps, when Dr. Horsley detected a material error in some part of

of them, in his *Remarks on the Obſervations made in the late Voyage, &c*, 1774.

" The Scholar's Inſtructor, or Hebrew Grammar, by Iſrael Lyons, Teacher of the Hebrew Tongue in the Univerſity of Cambridge," the 2d edit. &c, 1757, 8vo, was the production of his father; as was alſo another Treatiſe printed at the Cambridge preſs, under the title of " Obſervations and Enquiries relating to various parts of Scripture Hiſtory, 1761."

LYRA, the *Harp*, a conſtellation in the northern hemiſphere, containing 10 ſtars in Ptolomy's catalogue, 11 in Tycho's, 17 in Hevelius's, and 21 in the Britannic catalogue.

M.

MAC

M, In *Aſtronomical Tables*, &c, is uſed for *Meridional* or ſouthern; and ſometimes for *Meridian*, or mid-day.—In the Roman numeration, it denotes 1000, one thouſand.

MACHINE, denotes any thing that ſerves to augment, or to regulate moving powers: or it is any body deſtined to produce motion, ſo as to ſave either time or force. The word, in Greek, ſignifies an *Invention*, or *Art*: and hence, in ſtrictneſs, a machine is ſomething that conſiſts more in art and invention, than in the ſtrength and ſolidity of the materials; for which reaſon it is that the inventors of machines are called *Ingenieurs*, or *engineers*.

Machines are either ſimple or compound. The ſimple machines are the ſeven mechanical powers, viz, the lever, balance, pulley, wheel-and-axle, wedge, ſcrew, and inclined plane; which are otherwiſe called the ſimple mechanic powers.

Theſe ſimple machines ſerve for different purpoſes, according to the different ſtructures of them; and it is the buſineſs of the ſkilful mechaniſt to chooſe them, and combine them, in the manner that may be beſt adapted to produce the deſired effect. The lever is a very handy machine for many purpoſes, and its power immediately varied as the occaſion may require; when weights are to be raiſed only a little way, ſuch as ſtones out of quarries, &c. On the other hand, the wheel-and-axle ſerves to raiſe weights from the greateſt depth, or to the greateſt height. Pulleys, being eaſily carried, are therefore much employed in ſhips. The balance is uſeful for aſcertaining an equality of weight. The wedge is excellent for ſeparating the parts of bodies; and being impelled by the force of percuſſion, it is incomparably greater than the other powers. The ſcrew is uſeful for compreſſing or ſqueezing bodies together, and alſo for raiſing very heavy weights to a ſmall height; its great friction is even of conſiderable uſe, to preſerve the effect already produced by the machine.

Compound MACHINE, is formed from theſe ſimple machines, combined together for different purpoſes. The number of compound machines is almoſt infinite; and yet it would ſeem that the Ancients went far beyond the Moderns in the powers and effects of them; eſpecially their machines of war and architecture.

Accurate deſcriptions and drawings of machines

MAC

would be a very curious and uſeful work. But to make a collection of this kind as beneficial as poſſible, it ſhould contain alſo an analyſis of them; pointing out their advantages and diſadvantages, with the reaſons of the conſtructions; alſo the general problems implied in theſe conſtructions, with their ſolutions, ſhould be noticed. Though a complete work of this kind be ſtill wanting, yet many curious and uſeful particulars may be gathered from Strada, Beſſon, Beroaldus, Auguſtinus de Ramellis, Bockler, Leupold, Beyer, Limpergh, Van Zyl, Perault, and others; a ſhort account of whoſe works may be found in Wolfii Commentatio de Præcipuis Scriptis Mathematicis; Elem. Matheſ. Univ. tom. 5, pa. 84. To theſe may be added, Belidor's Architecture Hydraulique, Deſaguliers's Courſe of Experimental Philoſophy, and Emerſon's Mechanics. The Royal Academy of Sciences at Paris have alſo given a collection of machines and inventions approved of by them. This work, publiſhed by M. Gallon, conſiſts of 6 volumes in quarto, containing engraved draughts of the machines, with their deſcriptions annexed.

MACHINE, *Architectonical*, is an aſſemblage of pieces of wood ſo diſpoſed as that, by means of ropes and pulleys, a ſmall number of men may raiſe great loads, and lay them in their places: ſuch as cranes, &c.—— It is hard to conceive what ſort of machines the Ancients muſt have uſed to raiſe thoſe immenſe ſtones found in ſome of the antique buildings; as ſome of thoſe ſtill found in the walls of Balbeck in Turkey, the ancient Heliopolis, which are 63 feet long, 12 feet broad, and 12 feet thick, and which muſt weigh 6 or 7 hundred tons a piece.

Blowing MACHINE. See BELLOWS.

Boylean MACHINE. Mr. Boyle's Air-Pump.

Electrical MACHINE. See ELECTRICAL *Machine*.

Wind MACHINE. See ANEMOMETER, and WIND *Machine*.

Hydraulic, or *Water* MACHINE, is uſed either to ſignify a ſimple Machine, ſerving to conduct or raiſe water; as a ſluice, pump, and the like, or ſeveral of theſe acting together, to produce ſome extraordinary effect; as the

MACHINE *of Marli*. See MARLI. See alſo FIRE-*engine*, STEAM-*engine*, and WATER-*works*.

Military MACHINES, among the Ancients, were of

three kinds: the firſt ſerving to launch arrows, as the ſcorpion; or javelins, as the catapult; or ſtones, as the baliſta; or fiery darts, as the pyrabolus: the 2d ſort ſerving to beat down walls, as the battering ram and terebra: and the 3d ſort to ſhelter thoſe who approach the enemy's wall, as the tortoiſe or teſtudo, the vinea, and the towers of wood. See the reſpective articles.

The Machines of war now in uſe, conſiſt in artillery, including cannon, mortars, petards, &c.

MACLAURIN, (COLIN), a moſt eminent mathematician and philoſopher, was the ſon of a clergyman, and born at Kilmoddan in Scotland, in the year 1698. He was ſent to the univerſity of Glaſgow in 1709; where he continued five years, and applied to his ſtudies in a very intenſe manner, and particularly to the mathematics. His great genius for mathematical learning diſcovered itſelf ſo early as at 12 years of age; when, having accidentally met with a copy of Euclid's Elements in a friend's chamber, he became in a few days maſter of the firſt 6 books without any aſſiſtance: and it is certain, that in his 16th year he had invented many of the propoſitions which were afterwards publiſhed as part of his work intitled *Geometria Organica*. In his 15th year he took the degree of Maſter of Arts; on which occaſion he compoſed and publicly defended a theſis on the power of gravity, with great applauſe. After this he quitted the univerſity, and retired to a country ſeat of his uncle, who had the care of his education; his parents being dead ſome time. Here he ſpent two or three years in purſuing his favourite ſtudies; but, in 1717, at 19 years of age only, he offered himſelf a candidate for the profeſſorſhip of mathematics in the Mariſchal College of Aberdeen, and obtained it after a ten days trial, againſt a very able competitor.

In 1719, Mr. Maclaurin viſited London, where he left his *Geometria Organica* to print, and where he became acquainted with Dr. Hoadley then biſhop of Bangor, Dr. Clarke, Sir Iſaac Newton, and other eminent men; at which time alſo he was admitted a member of the Royal Society: and in another journey, in 1721, he contracted an intimacy with Martin Folkes, Eſq. the preſident of it, which continued during his whole life.

In 1722, lord Polwarth, plenipotentiary of the king of Great Britain at the congreſs of Cambray, engaged Maclaurin to go as a tutor and companion to his eldeſt ſon, who was then to ſet out on his travels. After a ſhort ſtay at Paris, and viſiting other towns in France, they fixed in Lorrain; where he wrote his piece, On the Percuſſion of Bodies, which gained him the prize of the Royal Academy of Sciences for the year 1724. But his pupil dying ſoon after at Montpelier, he returned immediately to his profeſſion at Aberdeen. He was hardly ſettled here, when he received an invitation to Edinburgh; the curators of that univerſity being deſirous that he ſhould ſupply the place of Mr. James Gregory, whoſe great age and infirmities had rendered him incapable of teaching. He had here ſome difficulties to encounter, ariſing from competitors, who had good intereſt with the patrons of the univerſity, and alſo from the want of an additional fund for the new profeſſor; which however at length were all ſurmounted, principally by the means of Sir Iſaac Newton. Accordingly, in Nov. 1725, he was introduced into the univerſity; as was at the ſame time his learned colleague and intimate friend, Dr. Alexander Monro, profeſſor of anatomy. After this, the Mathematical claſſes ſoon became very numerous, there being generally upwards of 100 ſtudents attending his Lectures every year; who being of different ſtandings and proficiency, he was obliged to divide them into four or five claſſes, in each of which he employed a full hour every day from the firſt of November to the firſt of June. In the firſt claſs he taught the firſt 6 books of Euclid's Elements, Plane Trigonometry, Practical Geometry, the Elements of Fortification, and an Introduction to Algebra. The ſecond claſs ſtudied Algebra, with the 11th and 12th books of Euclid, Spherical Trigonometry, Conic Sections, and the general Principles of Aſtronomy. The third went on in Aſtronomy and Perſpective, read a part of Newton's Principia, and had performed a courſe of experiments for illuſtrating them: he afterwards read and demonſtrated the Elements of Fluxions. Thoſe in the fourth claſs read a Syſtem of Fluxions, the Doctrine of Chances, and the remainder of Newton's Principia.

In 1734, Dr. Berkley, biſhop of Cloyne, publiſhed a piece called The Analiſt; in which he took occaſion, from ſome diſputes that had ariſen concerning the grounds of the fluxionary method, to explode the method itſelf; and alſo to charge mathematicians in general with infidelity in religion. Maclaurin thought himſelf included in this charge, and began an anſwer to Berkley's book: but other anſwers coming out, and as he proceeded, ſo many diſcoveries, ſo many new theories and problems occurred to him, that inſtead of a vindicatory pamphlet, he produced a Complete Syſtem of Fluxions, with their application to the moſt conſiderable problems in Geometry and Natural Philoſophy. This work was publiſhed at Edinburgh in 1742, 2 vols 4to; and as it coſt him infinite pains, ſo it is the moſt conſiderable of all his works, and will do him immortal honour, being indeed the moſt complete treatiſe on that ſcience that has yet appeared.

In the mean time, he was continually obliging the public with ſome obſervation or performance of his own, ſeveral of which were publiſhed in the 5th and 6th volumes of the Medical Eſſays at Edinburgh. Many of them were likewiſe publiſhed in the Philoſophical Tranſactions; as the following: 1. On the Conſtruction and Meaſure of Curves, vol. 30.—2. A New Method of deſcribing all kinds of Curves, vol. 30.—3. On Equations with Impoſſible Roots, vol. 34.—4. On the Roots of Equations, &c, vol. 34.—5. On the Deſcription of Curve Lines, vol. 39.—6. Continuation of the ſame, vol. 39.—7. Obſervations on a Solar Eclipſe, vol. 40.—8. A Rule for finding the Meridional Parts of a Spheroid with the ſame Exactneſs as in a Sphere, vol. 41.—9. An Account of the Treatiſe of Fluxions, vol. 42.—10. On the Baſes of the Cells where the Bees depoſit their Honey, vol. 42.

In the midſt of theſe ſtudies, he was always ready to lend his aſſiſtance in contriving and promoting any ſcheme which might contribute to the public ſervice. When the earl of Morton went, in 1739, to viſit his eſtates in Orkney and Shetland, he requeſted Mr. Maclaurin to aſſiſt him in ſettling the geography of thoſe countries, which is very erroneous in all our maps; to examine their natural hiſtory, to ſurvey the coaſts, and to take the meaſure of a degree of the meridian. Mac-

laurin's family affairs would not permit him to comply with this requeſt: he drew up however a memorial of what he thought neceſſary to be obſerved, and furniſhed proper inſtruments for the work, recommending Mr. Short, the noted optician, as a fit operator for the management of them.

Mr. Maclaurin had ſtill another ſcheme for the improvement of geography and navigation, of a more extenſive nature; which was the opening a paſſage from Greenland to the South Sea by the North Pole. That ſuch a paſſage might be found, he was ſo fully perſuaded, that he uſed to ſay, if his ſituation could admit of ſuch adventures, he would undertake the voyage, even at his own charge. But when ſchemes for finding it were laid before the parliament in 1741, and he was conſulted by ſeveral perſons of high rank concerning them, and before he could finiſh the memorials he propoſed to ſend, the premium was limited to the diſcovery of a north-weſt paſſage: and he uſed to regret that the word Weſt was inſerted, becauſe he thought that paſſage, if at all to be found, muſt lie not far from the pole.

In 1745, having been very active in fortifying the city of Edinburgh againſt the rebel army, he was obliged to fly from thence into England, where he was invited by Dr. Herring, archbiſhop of York, to reſide with him during his ſtay in this country. In this expedition however, being expoſed to cold and hardſhips, and naturally of a weak and tender conſtitution, which had been much more enfeebled by cloſe application to ſtudy, he laid the foundation of an illneſs which put an end to his life, in June 1746, at 48 years of age, leaving his widow with two ſons and three daughters.

Mr. Maclaurin was a very good, as well as a very great man, and worthy of love as well as admiration. His peculiar merit as a philoſopher was, that all his ſtudies were accommodated to general utility; and we find, in many places of his works, an application even of the moſt abſtruſe theories, to the perfecting of mechanical arts. For the ſame purpoſe, he had reſolved to compoſe a courſe of Practical Mathematics, and to reſcue ſeveral uſeful branches of the ſcience from the ill treatment they often met with in leſs ſkilful hands. Theſe intentions however were prevented by his death; unleſs we may reckon, as a part of his intended work, the tranſlation of Dr. David Gregory's Practical Geometry, which he reviſed, and publiſhed with additions, in 1745.

In his lifetime, however, he had frequent opportunities of ſerving his friends and his country by his great ſkill. Whatever difficulty occurred concerning the conſtructing or perfecting of machines, the working of mines, the improving of manufactures, the conveying of water, or the execution of any public work, he was always ready to reſolve it. He was employed to terminate ſome diſputes of conſequence that had ariſen at Glaſgow concerning the gauging of veſſels; and for that purpoſe preſented to the commiſſioners of the exciſe two elaborate memorials, with their demonſtrations, containing rules by which the officers now act. He made alſo calculations relating to the proviſion, now eſtabliſhed by law, for the children and widows of the Scotch clergy, and of the profeſſors in the univerſities, entitling them to certain annuities and ſums, upon the voluntary annual payment of a certain ſum by the incumbent. In contriving and adjuſting this wiſe and uſeful ſcheme, he beſtowed a great deal of labour, and contributed not a little towards bringing it to perfection.

Of his works, we have mentioned his *Geometria Organica*, in which he treats of the deſcription of curve lines by continued motion; as alſo of his piece which gained the prize of the Royal Academy of Sciences in 1724. In 1740, he likewiſe ſhared the prize of the ſame Academy, with the celebrated D. Bernoulli and Euler, for reſolving the problem relating to the motion of the tides from the theory of gravity: a queſtion which had been given out the former year, without receiving any ſolution. He had only ten days to draw this paper up in, and could not find leiſure to tranſcribe a fair copy; ſo that the Paris edition of it is incorrect. He afterwards reviſed the whole, and inſerted it in his Treatiſe of Fluxions; as he did alſo the ſubſtance of the former piece. Theſe, with the Treatiſe of Fluxions, and the pieces printed in the Medical Eſſays and the Philoſophical Tranſactions, a liſt of which is given above, are all the writings which our author lived to publiſh. Since his death, however, two more volumes have appeared; his *Algebra*, and his *Account of Sir Iſaac Newton's Philoſophical Diſcoveries*. The Algebra, though not finiſhed by himſelf, is yet allowed to be excellent in its kind; containing, in no large volume, a complete elementary treatiſe of that ſcience, as far as it has hitherto been carried; beſides ſome neat analytical papers on curve lines. His Account of Newton's Philoſophy was occaſioned in the following manner:—Sir Iſaac dying in the beginning of 1728, his nephew, Mr. Conduitt, propoſed to publiſh an account of his life, and deſired Mr. Maclaurin's aſſiſtance. The latter, out of gratitude to his great benefactor, cheerfully undertook, and ſoon finiſhed, the Hiſtory of the Progreſs which Philoſophy had made before Newton's time; and this was the firſt draught of the work in hand; which not going forward, on account of Mr. Conduitt's death, was returned to Mr. Maclaurin. To this he afterwards made great additions, and left it in the ſtate in which it now appears. His main deſign ſeems to have been, to explain only thoſe parts of Newton's philoſophy, which have been controverted: and this is ſuppoſed to be the reaſon why his grand diſcoveries concerning light and colours are but tranſiently and generally touched upon; for it is known, that whenever the experiments, on which his doctrine of light and colours is founded, had been repeated with due care, this doctrine had not been conteſted; while his accounting for the celeſtial motions, and the other great appearances of nature, from gravity, had been miſunderſtood, and even attempted to be ridiculed.

MACULÆ, in Aſtronomy, are dark ſpots appearing on the luminous ſurfaces of the ſun and moon, and even ſome of the planets.

The Solar Maculæ are dark ſpots of an irregular and changeable figure, obſerved in the face of the ſun. Theſe were firſt obſerved in November and December of the year 1610, by Galileo in Italy, and Harriot in England, unknown to, and independent of each other, ſoon after they had made or procured teleſcopes. They were afterwards alſo obſerved by Scheiner, Hevelius, Flamſteed, Caſſini, Kirch, and others. See Philoſ. Tranſ. vol. 1, pa. 274, and vol. 64, pa. 194.

There-

There have been various obſervations made of the phenomena of the ſolar maculæ, and hypotheſes invented for explaining them. Many of theſe maculæ appear to conſiſt of heterogeneous parts; the darker and denſer being called, by Hevelius, nuclei, which are encompaſſed as it were with atmoſpheres, ſomewhat rarer and leſs obſcure; but the figure, both of the nuclei and entire maculæ, is variable. Theſe maculæ are often ſubject to ſudden mutations: In 1644 Hevelius obſerved a ſmall thin macula, which in two days time grew to ten times its bulk, appearing alſo much darker, and having a larger nucleus: the nucleus began to fail ſenſibly before the ſpot diſappeared; and before it quite vaniſhed, it broke into four, which re-united again two days after. Some maculæ have laſted 2, 3, 10, 15, 20, 30, but ſeldom 40 days; though Kirchius obſerved one in 1681, that was viſible from April 26th to the 17th of July. It is found that the ſpots move over the ſun's diſc with a motion ſomewhat ſlacker near the edge than in the middle parts; that they contract themſelves near the limb, and in the middle appear larger; that they often run into one in the diſc, though ſeparated near the centre; that many of them firſt appear in the middle, and many diſappear there; but that none of them deviate from their path near the horizon; whereas Hevelius, obſerving Mercury in the ſun near the horizon, found him too low, being depreſſed 27″ beneath his former path.

From theſe phenomena are collected the following conſequences. 1. That ſince Mercury's depreſſion below his path ariſes from his parallax, the maculæ, having no parallax from the ſun, are much nearer him than that planet.

2. That, ſince they riſe and diſappear again in the middle of the ſun's diſc, and undergo various alterations with regard both to bulk, figure, and denſity, they muſt be formed *de novo*, and again diſſolved about the ſun; and hence ſome have inferred, that they are a kind of ſolar clouds, formed out of his exhalations; and if ſo, the ſun muſt have an atmoſphere.

3. Since the ſpots appear to move very regularly about the ſun, it is hence inferred, that it is not that they really move, but that the ſun revolves round his axis, and the ſpots accompany him, in the ſpace of 27 days 12 hours 20 minutes.

4. Since the ſun appears with a circular diſc in every ſituation, his figure, as to ſenſe, muſt be ſpherical.

The magnitude of the ſurface of a ſpot may be eſtimated by the time of its tranſit over a hair in a fixed teleſcope. Galileo eſtimates ſome ſpots as larger than both Aſia and Africa put together: but if he had known more exactly the ſun's parallax and diſtance, as they are known now, he would have found ſome of thoſe ſpots much larger than the whole ſurface of the earth. For, in 1612, he obſerved a ſpot ſo large as to be plainly viſible to the naked eye; and therefore it ſubtended an angle of about a minute. But the earth, ſeen at the diſtance of the ſun, would ſubtend an angle of only about 17″: therefore the diameter of the ſpot was to the diameter of the earth, as 60 to 17, or $3\frac{1}{2}$ to 1 nearly; and conſequently the ſurface of the ſpot, if circular, to a great circle of the earth, as $12\frac{1}{4}$ to 1, and to the whole ſurface of the earth, as $12\frac{1}{4}$ to 4, or nearly 3 to 1. Gaſſendus obſerved a ſpot whoſe breadth was $\frac{1}{30}$ of the ſun's diameter, and which therefore ſubtended an angle at the eye of above a minute and a half; and conſequently its ſurface was above ſeven times larger than the ſurface of the whole earth. He ſays he obſerved above 40 ſpots at once, though without ſenſibly diminiſhing the light of the ſun.

Various opinions have been formed concerning the nature, origin, and ſituation of the ſolar ſpots; but the moſt probable ſeems to be that of Dr. Wilſon, profeſſor of practical aſtronomy in the univerſity of Glaſgow. By attending particularly to the different phaſes preſented by the umbra, or ſhady zone, of a ſpot of an extraordinary ſize that appeared on the ſun, in the month of November 1769, during its progreſs over the ſolar diſc, Dr. Wilſon was led to form a new and ſingular conjecture on the nature of theſe appearances; which he afterwards greatly ſtrengthened by repeated obſervations. The reſults of theſe obſervations are, that the ſolar maculæ are cavities in the body of the ſun; that the nucleus, as the middle or dark part has uſually been called, is the bottom of the excavations; and that the umbra, or ſhady zone ſurrounding it, is the ſhelving ſides of the cavity. Dr. Wilſon, beſides having ſatisfactorily aſcertained the reality of theſe immenſe excavations in the body of the ſun, has alſo pointed out a method of meaſuring the depth of them. He eſtimates, in particular, that the nucleus, or bottom of the large ſpot above-mentioned, was not leſs than a ſemidiameter of the earth, or about 4000 miles below the level of the ſun's ſurface; while its other dimenſions were of a much larger extent. He obſerved that a ſpot near the middle of the ſun's diſc, is ſurrounded equally on all ſides with its umbra; but that when, by its apparent motion over the ſun's diſc, it comes near the weſtern limb, that part of the umbra which is next the ſun's centre gradually diminiſhes in breadth, till near the edge of the limb it totally diſappears; whilſt the umbra on the other ſide of it is little or nothing altered. After a ſemirevolution of the ſun on his axis, if the the ſpot appear again, it will be on the oppoſite ſide of the diſc, or on the left hand, and the part of the umbra which had before diſappeared, is now plainly to be ſeen; while the umbra on the other ſide of the ſpot, ſeems to have vaniſhed in its turn; being hid from the view by the upper edge of the excavation, from the oblique poſition of its ſloping ſides with reſpect to the eye. But as the ſpot advances on the ſun's diſc, this umbra, or ſide of the cavity, comes in ſight; at firſt appearing narrow, but afterwards gradually increaſing in breadth, as the ſpot moves towards the middle of the diſc. Which appearances perfectly agree with the phaſes that are exhibited by an excavation in a ſpherical body, revolving on its axis; the bottom of the cavity being painted black, and the ſides lightly ſhaded.

From theſe, and other obſervations, it is inferred, that the body of the ſun, at the depth of the nucleus, emits little or no light, when ſeen at the ſame time, and compared with that reſplendent, and probably, in ſome degree, fluid ſubſtance, that covers his ſurface.

This manner of conſidering theſe phenomena, naturally gives riſe to many curious ſpeculations and inquiries. It is natural, for inſtance, to inquire, by what great commotion this refulgent matter is thrown up on all ſides, ſo as to expoſe to our view the darker part of the

the ſun's body, which was before covered by it? what is the nature of this ſhining matter? and why, when an excavation is made in it, is the luſtre of this ſhining ſubſtance, which forms the ſhelving ſides of the cavity, ſo far diminiſhed, as to give the whole the appearance of a ſhady zone, or darkiſh atmoſphere, ſurrounding the denuded part of the ſun's body? On theſe, and many other ſubjects, Dr. Wilſon has advanced ſome ingenious conjectures; for which ſee the Philoſ. Tranſ. vol. 64, art. 1. See alſo ſome remarks on this theory, by Mr. Woolaſton, in the ſame vol. pa. 337, &c.

MADRIER, in Artillery, is a thick plank, armed with plates of iron, and having a cavity ſufficient to receive the mouth of a petard, with which it is applied againſt a gate, or any thing elſe intended to be broken down.

This term is alſo applied to certain flat beams, fixed to the bottom of a moat, to ſupport a wall.

There are alſo Madriers lined with tin, and covered with earth; ſerving as defences againſt artificial fires, in lodgments, &c, where there is need of being covered overhead.

MÆSTLIN (MICHAEL), in Latin Mæſtlinus, a noted aſtronomer of Germany, was born in the duchy of Wittemberg; but ſpent his youth in Italy, where he made a ſpeech in favour of Copernicus's ſyſtem, which brought Galileo over from Ariſtotle and Ptolomy, to whom he was before wholly devoted. He afterwards returned to Germany, and became profeſſor of mathematics at Tubingen; where, among his other ſcholars, he taught the celebrated Kepler, who has commended ſeveral of his ingenious inventions, in his Aſtronomia Optica.

Mæſtlin publiſhed many mathematical and aſtronomical works; and died in 1590.—Though Tycho Brahe did not aſſent to Mæſtlin's opinion, yet he allowed him to be an extraordinary perſon, and deeply ſkilled in the ſcience of aſtronomy.

MAGAZINE, a place in which ſtores are kept, of arms, ammunition, proviſions, &c.

Artillery MAGAZINE, or the Magazine to a field battery, is made about 25 or 30 yards behind the battery, towards the parallels, and at leaſt 3 feet under ground, to receive the powder, loaded ſhells, port-fires, &c.—Its roof and ſides ſhould be well ſecured with boards, to prevent the earth from falling in: it has a door, and a double trench or paſſage ſunk from the magazine to the battery, the one to enter, and the other to go out at, to prevent confuſion. Sometimes traverſes are made in the paſſages, to prevent ricochet ſhot from entering the magazine.

Powder-MAGAZINE, is the place where powder is kept in large quantities. Authors differ very much with regard to the ſituation and conſtruction of theſe magazines; but all agree, that they ought to be arched and bomb-proof. In fortifications, they were formerly placed in the rampart; but of late they have been built in different parts of the town. The firſt powder-magazines were made with Gothic arches: but M. Vauban finding theſe too weak, conſtructed them of a ſemicircular form, the dimenſions being 60 feet long within, and 25 feet broad; the foundations are 8 or 9 feet thick, and 8 feet high from the foundation to the ſpring of the arch; alſo the floor 2 feet from the ground, to keep it from dampneſs.

It is a conſtant obſervation, that after the centering of ſemicircular arches is ſtruck, they ſettle at the crown, and riſe up at the hances, even with a ſtraight horizontal extrados; and ſtill much more ſo in powder-magazines, where the outſide at top is formed, like the roof of a houſe, by inclined planes joining in an angle over the top of the arch, to give a proper deſcent to the rain; which effects are exactly what might be expected from the true theory of arches. Now, this ſhrinking of the arches, as it muſt be attended with very bad conſequences, by breaking the texture of the cement after it has in ſome degree been dried, and alſo by opening the joints of the vouſoirs at one end, ſo a remedy is provided for this inconvenience, with regard to bridges, by the arch of equilibration, in my book on the Principles of Bridges: but as the ill conſequences of it are much greater in powder-magazines, in queſtion 96 of my Mathematical Miſcellany, I propoſed to find an arch of equilibration for them alſo; which queſtion was there reſolved both by Mr. Wildbore and myſelf, both upon general principles, and which I illuſtrated by an application to a particular caſe, which is there conſtructed, and accompanied with a table of numbers for that purpoſe. Thus, if ALKMB repreſent a vertical tranſverſe ſection of the arch, the roof forming an angle LKM of 112° 37′, alſo PC an ordinate parallel to the horizon taken in any part, and IC perpendicular to the ſame; then for properly conſtructing the curve ſo as to be the ſtrongeſt, or an arch of equilibration in all its parts, the correſponding values of PC and CI will be as in the following table, where thoſe numbers may denote any lengths whatever, either inches, or feet, or half-yards.

Value of PC	Value of IC

MAGAZINE, or *Powder-Room*, on ſhip-board, is a cloſe room or ſtore-houſe, built in the fore or after part of the hold, in which to preſerve the gunpowder for the uſe of the ſhip. This apartment is ſtrongly ſecured againſt fire, and no perſon is allowed to enter it with a lamp or candle: it is therefore lighted, as occaſion requires, by means of the candles or lamps in the light-room contiguous to it.

MAGELLANIC-CLOUDS, whitiſh appearances like clouds, ſeen in the heavens towards the ſouth pole, and having the ſame apparent motion as the ſtars. They are three in number, two of them near each other.—The largeſt lies far from the ſouth pole; but the other two are not many degrees more remote from it than the neareſt conſpicuous ſtar, that is, about 11 degrees.

Mr. Boyle conjectures that if theſe clouds were ſeen through a good teleſcope, they would appear to be multitudes of ſmall ſtars, like the milky way.

MAGIC LANTERN, an optical machine, by means of which ſmall painted images are repreſented on the wall of a dark room, magnified to any ſize at pleaſure. This machine was contrived by Kircher, (ſee his Ars Magna Lucis and Umbræ, pa. 768); and it was ſo called, becauſe the images were made to repreſent ſtrange phantaſms, and terrible apparitions, which have been taken for the effect of magic, by ſuch as were ignorant of the ſecret.

This machine is compoſed of a concave ſpeculum, from 4 to 12 inches diameter, reflecting the light of a candle through the ſmall hole of a tube, at the end of which is fixed a double convex lens of about 3 inches focus. Between the two are ſucceſſively placed, many ſmall plain glaſſes, painted with various figures, uſually ſuch as are the moſt formidable and terrifying to the ſpectators, when repreſented at large on the oppoſite wall.

Thus, (Pl. 13, fig. 14) ABCD is a common tin lantern, to which is added a tube FG to draw out. In H is fixed the metallic concave ſpeculum, from 4 to 12 inches diameter; or elſe, inſtead of it, near the extremity of the tube, there muſt be placed a convex lens, conſiſting of a ſegment of a ſmall ſphere, of but a few inches in diameter. The uſe of this lens is to throw a ſtrong light upon the image; and ſometimes a concave ſpeculum is uſed with the lens, to render the image ſtill more vivid. In the focus of the concave ſpeculum or lens, is placed the lamp L; and within the tube, where it is ſoldered to the ſide of the lantern, is placed a ſmall lens, convex on both ſides, being a portion of a ſmall ſphere, having its focus about the diſtance of 3 inches. The extreme part of the tube FM is ſquare, and has an aperture quite through, ſo as to receive an oblong frame NO paſſing into it; in which frame there are round holes, of an inch or two in diameter. Anſwering to the magnitude of theſe holes there are drawn circles on a plain thin glaſs; and in theſe circles are painted any figures, or images, at pleaſure, with tranſparent water colours. Theſe images fitted into the frame, in an inverted poſition, at a ſmall diſtance from the focus of the lens I, will be projected on an oppoſite white wall of a dark room, in all their colours, greatly magnified, and in an erect poſition. By having the inſtrument ſo contrived, as that the lens I may move on a ſlide, the focus may be made, and conſequently the image appear diſtinct, at almoſt any diſtance.

Or thus: Every thing being managed as in the former caſe, into the ſliding tube FG, inſert another convex lens K, the ſegment of a ſphere rather larger than I. Now, if the picture be brought nearer to I than the diſtance of the focus, diverging rays will be propagated as if they proceeded from the object; wherefore, if the lens K be ſo placed, as that the object be very near its focus, the image will be exhibited on the wall, greatly magnified.

MAGIC SQUARE, is a ſquare figure, formed of a ſeries of numbers in arithmetical progreſſion, ſo diſpoſed in parallel and equal ranks, as that the ſums of each row, taken either perpendicularly, horizontally, or diagonally, are equal to one another. As the annexed ſquare, formed of theſe nine numbers, 1, 2, 3, 4, 5, 6, 7, 8, 9, where the ſum of the three figures in every row, in all directions, is always the ſame number, viz 15. But if the ſame numbers be placed in this natural order, the firſt being 1, and the laſt of them a ſquare number, they will form what is called a natural ſquare. As in the firſt 25 numbers, viz, 1, 2, 3, 4, 5, &c to 25.

where every row and diagonal in the magic ſquare makes juſt the ſum 65, being the ſame as the two diagonals of the natural ſquare.

It is probable that theſe magic ſquares were ſo called, both becauſe of this property in them, viz, that the ranks in every direction make the ſame ſum, appeared extremely ſurpriſing, eſpecially in the more ignorant ages, when mathematics paſſed for magic, and becauſe alſo of the ſuperſtitious operations they were employed in, as the conſtruction of taliſmans, &c; for, according to the childiſh philoſophy of thoſe days, which aſcribed virtues to numbers, what might not be expected from numbers ſo ſeemingly wonderful!

The Magic Square was held in great veneration among the Egyptians, and the Pythagoreans their diſciples, who, to add more efficacy and virtue to this ſquare, dedicated it to the then known ſeven planets divers ways, and engraved it upon a plate of the metal that was eſteemed in ſympathy with the planet. The ſquare thus dedicated, was incloſed by a regular polygon, inſcribed in a circle, which was divided into as many equal parts as there were units in the ſide of the ſquare; with the names of the angels of the planet, and the ſigns of the zodiac written upon the void ſpaces between the polygon and the circumference of the circumſcribed circle. Such a taliſman or metal they vainly imagined would, upon occaſion, befriend the perſon who carried it about him.

To Saturn they attributed the ſquare of 9 places or cells, the ſide being 3, and the ſum of the numbers in every row 15: to Jupiter the ſquare of 16 places, the ſide being 4, and the amount of each row 34: to Mars the ſquare of 25 places, the ſide being 5, and the amount of each row 65: to the Sun the ſquare with 36 places, the ſide being 6, and the ſum of each row 111: to Venus the ſquare of 49 places, the ſide being 7, and the amount of each row 175: to Mercury the ſquare with 64 places, the ſide being 8, and the ſum of each

each row 260: and to the Moon the ſquare of 81 places, the ſide being 9, and the amount of each row 369. Finally, they attributed to imperfect matter, the ſquare with 4 diviſions, having 2 for its ſide; and to God the ſquare of only one cell, the ſide of which is alſo an unit, which multiplied by itſelf, undergoes no change.

However, what was at firſt the vain practice of conjurers and makers of taliſmans, has ſince become the ſubject of a ſerious reſearch among mathematicians. Not that they imagine it will lead them to any thing of ſolid uſe or advantage; but rather as it is a kind of play, in which the difficulty makes the merit, and it may chance to produce ſome new views of numbers, which mathematicians will not loſe the occaſion of.

It would ſeem that Eman. Moſchopulus, a Greek author of no high antiquity, is the firſt now known of, who has ſpoken of magic ſquares: he has left ſome rules for their conſtruction; though, by the age in which he lived, there is reaſon to imagine he did not look upon them merely as a mathematician.

In the treatiſe of Cornelius Agrippa, ſo much accuſed of magic, are found the ſquares of ſeven numbers, viz, from 3 to 9 inclufive, diſpoſed magically; and it is not to be ſuppoſed that thoſe ſeven numbers were preferred to all others without ſome good reaſon: indeed it is becauſe their ſquares, according to the ſyſtem of Agrippa and his followers, are planetary. The ſquare of 3, for inſtance, belongs to Saturn; that of 4 to Jupiter; that of 5 to Mars; that of 6 to the Sun; that of 7 to Venus: that of 8 to Mercury; and that of 9 to the Moon.

M. Bachet applied himſelf to the ſtudy of magic ſquares, on the hint he had taken from the planetary ſquares of Agrippa, as being unacquainted with Moſchopulus's work, which is only in manuſcript in the French king's library; and, without the aſſiſtance of any author, he found out a new method for the ſquares of uneven numbers; for inſtance, 25, or 49, &c; but he could not ſucceed with thoſe that have even roots.

M. Frenicle next engaged in this ſubject. It was the opinion of ſome, that although the firſt 16 numbers might be diſpoſed 20922789888000 different ways in a natural ſquare, yet they could not be diſpoſed more than 16 ways in a magic ſquare; but M. Frenicle ſhewed, that they might be thus diſpoſed in 878 different ways.

To this buſineſs he thought fit to add a difficulty that had not yet been conſidered; which was, to take away the marginal numbers quite around, or any other circumference at pleaſure, or even ſeveral of ſuch circumferences, and yet that the remainder ſhould ſtill be magical.

Again he inverted that condition, and required that any circumference taken at pleaſure, or even ſeveral circumferences, ſhould be inſeparable from the ſquare; that is, that it ſhould ceaſe to be magical when they were removed, and yet continue magical after the removal of any of the reſt. M. Frenicle however gives no general demonſtration of his methods, and it often ſeems that he has no other guide but chance. It is true, his book was not publiſhed by himſelf, nor did it appear till after his death, viz, in 1693.

In 1703 M. Poignard, canon of Bruſſels, publiſhed a treatiſe on ſublime magic ſquares. Before his time there had been no magic ſquares made, but for ſerieſes of natural numbers that formed a ſquare; but M. Poignard made two very conſiderable improvements. 1ſt, Inſtead of taking all the numbers that fill a ſquare, for inſtance, the 36 ſucceſſive numbers, which would fill all the cells of a natural ſquare whoſe ſide is 6, he only takes as many ſucceſſive numbers as there are units in the ſide of the ſquare, which in this caſe are 6; and theſe ſix numbers alone he diſpoſes in ſuch manner, in the 36 cells, that none of them occur twice in the ſame rank, whether it be horizontal, vertical, or diagonal; whence it follows, that all the ranks, taken all the ways poſſible, muſt always make the ſame ſum; and this method M. Poignard calls repeated progreſſions. 2d, Inſtead of being confined to take theſe numbers according to the ſeries and ſucceſſion of the natural numbers, that is in arithmetical progreſſion, he takes them likewiſe in a geometrical progreſſion; and even in an harmonical progreſſion, the numbers of all the ranks always following the ſame kind of progreſſion: he makes ſquares of each of theſe three progreſſions repeated.

M. Poignard's book gave occaſion to M. de la Hire to turn his thoughts to the ſame ſubject, which he did with ſuch ſucceſs, that he greatly extended the theory of magic ſquares, as well for even numbers as thoſe that are uneven; as may be ſeen at large in the Memoirs of the Royal Academy of Sciences, for the years 1705 and 1710. See alſo Saunderſon's Algebra, vol. 1, pa. 354, &c; as alſo Ozanam's Mathematical Recreations, who lays down the following eaſy method of filling up a magic ſquare.

To form a magic ſquare of an odd number of terms in the arithmetic progreſſion 1, 2, 3, 4, &c. Place the leaſt term 1 in the cell immediately under the middle, or central one, and the reſt of the terms, in their natural order, in a deſcending diagonal direction, till they run off either at the bottom, or on the ſide: when the number runs off at the bottom, carry it to the uppermoſt cell, that is not occupied, of the ſame column that it would have fallen in below, and then proceed deſcending diagonalwiſe again as far as you can, or till the numbers either run off at bottom or ſide, or are interrupted by coming at a cell already filled: now when any number runs off at the right-hand ſide, then bring it to the fartheſt cell on the left-hand of the ſame row or line it would have fallen in towards the right-hand: and when the progreſs diagonalwiſe is interrupted by meeting with a cell already occupied by ſome other number, then deſcend diagonally to the left from this cell till an empty one is met with, where enter it; and thence proceed as before.

Thus, to make a magic ſquare of the 49 numbers 1, 2, 3, 4, &c. Firſt place the 1 next below the centre cell, and thence deſcend to the right till the 4 runs off at the bottom, which therefore carry to the top corner on the ſame column as it would have fallen in; but as runs off at the ſide, bring it to the beginning of the ſecond line, and

22	47	16	41	10	35	4
5	23	48	17	42	11	29
30	6	24	49	18	36	12
13	31	7	25	43	19	37
38	14	32	1	26	44	20
21	39	8	33	2	27	45
46	15	40	9	34	3	28

and thence deſcend to the right till they arrive at the cell occupied by 1; carry the 8 therefore to the next diagonal cell to the left, and ſo proceed till 10 run off at the bottom, which carry therefore to the top of its column, and ſo proceed till 13 runs off at the ſide, which therefore bring to the beginning of the ſame line, and thence proceed till 15 arrives at the cell occupied by 8; from this therefore deſcend diagonally to the left; but as 16 runs off at the bottom, carry it to the top of its proper column, and thence deſcend till 21 run off at the ſide, which is therefore brought to the beginning of its proper line; but as 22 arrives at the cell occupied by 15, deſcend diagonally to the left, which brings it into the 1ſt column, but off at the bottom, and therefore it is carried to the top of that column; thence deſcending till 29 runs off both at bottom and ſide, which therefore carry to the higheſt unoccupied cell in the laſt column; and here, as 30 runs off at the ſide, bring it to the beginning of its proper column, and thence deſcend till 35 runs off at the bottom, which therefore carry to the beginning or top of its own column; and here, as 36 meets with the cell occupied by 29, it is brought from thence diagonally to the left; thence deſcending, 38 runs off at the ſide, and therefore it is brought to the beginning of its proper line; thence deſcending, 41 runs off at the bottom, which therefore is carried to the beginning or top of its column; from whence deſcending, 43 arrives at the cell occupied by 36, and therefore it is brought down from thence to the left; thence deſcending, 46 runs off at the ſide, which therefore is brought to the beginning of its line; but here, as 47 runs off at the bottom, it is carried to the beginning or top of its column, from whence deſcending with 48 and 49, the ſquare is completed, the ſum of every row and column and diagonal making juſt 175.

There are many other ways of filling up ſuch ſquares, but none that are eaſier than the above one.

It was obſerved before, that the ſum of the numbers in the rows, columns and diagonals, was 15 in the ſquare of 9 numbers, 34 in a ſquare of 16, 65 in a ſquare of 25, &c.; hence then is derived a method of finding the ſums of the numbers in any other ſquare, viz, by taking the ſucceſſive differences till they become equal, and then adding them ſucceſſively to produce or find out the amount of the following ſums. Thus,

Side	Cells	Sums	Diffs.		
0	0	0			
1	1	1	1		
2	4	5	4	3	
3	9	15	10	6	3
4	16	34	19	9	3
5	25	65	31	12	3
6	36	111	46	15	3
7	49	175	64	18	3
8	64	260	85	21	3
9	81	369	109	24	3
10	100	505	136	27	3
				30	

having ranged the ſides and cells in two columns, and a few of the firſt ſums in a third column, take the firſt differences of theſe, which will be 1, 4, 10, 19, &c, as in the 4th column; and of theſe take the differences 0, 3, 6, 9, 12, &c, as in the 5th column; and again, of theſe the differences 3, 3, 3 &c, as in the 6th or laſt column. Then, returning back again, add always 3, the conſtant laſt or 3d difference, to the laſt found of the 2d differences, which will complete the remainder of the column of theſe, viz, 15, 18, 21, 24, &c: then add theſe 2d differences to the laſt found of the 1ſt differences, which will complete the column of theſe, viz, giving 31, 46, 64, &c: laſtly, add always theſe correſponding 1ſt differences to the laſt found number or amount of the ſums, and the column of ſums will thus be completed.

Again, like as the terms of an arithmetical progreſſion arranged magically, give the ſame ſum in every row &c, ſo the terms of a geometrical ſeries arranged magically give the ſame product in every row &c, by multiplying the numbers continually together; ſo this progreſſion 1, 2, 4, 8, 16, &c, arranged as in the margin, gives, for each continual product, 4096 in every row &c, which is juſt the cube of the middle term, 16.

8	256	2
4	16	64
128	1	32

Alſo, the terms of an harmonical progreſſion being ranged magically, as in the margin, have the terms in each row &c in harmonical progreſſion.

1260	840	630
504	420	360
315	280	252

The ingenious Dr. Franklin, it ſeems, carried this curious ſpeculation farther than any of his predeceſſors in the ſame way. He conſtructed both a *magic ſquare of ſquares*, and a *magic circle of circles*, the deſcription of which is as follows. The magic ſquare of ſquares is formed by dividing the great ſquare as in fig. 1, Pl. 15. The great ſquare is divided into 256 little ſquares, in which all the numbers from 1 to 256, or the ſquare of 16, are placed, in 16 columns, which may be taken either horizontally or vertically. Their chief properties are as follow:

1. The ſum of the 16 numbers in each column or row, vertical or horizontal, is 2056.

2. Every half column, vertical and horizontal, makes 1028, or juſt one half of the ſame ſum 2056.

3. Half a diagonal aſcending, added to half a diagonal deſcending, makes alſo the ſame ſum 2056; taking theſe half diagonals from the ends of any ſide of the ſquare to the middle of it; and ſo reckoning them either upward or downward; or ſideways from right to left, or from left to right.

4. The ſame with all the parallels to the half diagonals, as many as can be drawn in the great ſquare: for any two of them being directed upward and downward, from the place where they begin, to that where they end, their ſums ſtill make the ſame 2056. Alſo the ſame holds true downward and upward; as well as if taken ſideways to the middle, and back to the ſame ſide again. Only one ſet of theſe half diagonals and their parallels, is drawn in the ſame ſquare upward and downward; but another ſet may be drawn from any of the other three ſides.

5. The four corner numbers in the great ſquare added to the four central numbers in it, make 1028, the

half

half ſum of any vertical or horizontal column, which contains 16 numbers; and alſo equal to half a diagonal or its parallel.

6. If a ſquare hole, equal in breadth to four of the little ſquares or cells, be cut in a paper, through which any of the 16 little cells in the great ſquare may be ſeen, and the paper be laid upon the great ſquare; the ſum of all the 16 numbers, ſeen through the hole, is always equal to 2056, the ſum of the 16 numbers in any horizontal or vertical column.

The *Magic Circle of Circles*, fig. 2, pl. 15, by the ſame author, is compoſed of a ſeries of numbers, from 12 to 75 incluſive, divided into 8 concentric circular ſpaces, and ranged in 8 radii of numbers, with the number 12 in the centre; which number, like the centre, is common to all theſe circular ſpaces, and to all the radii.

The numbers are ſo placed, that 1ſt, the ſum of all thoſe in either of the concentric circular ſpaces above mentioned, together with the central number 12, amount to 360, the ſame as the number of degrees in a circle.

2. The numbers in each radius alſo, together with the central number 12, make juſt 360.

3. The numbers in half of any of the above circular ſpaces, taken either above or below the double horizontal line, with half the central number 12, make juſt 180, or half the degrees in a circle.

4. If any four adjoining numbers be taken, as if in a ſquare, in the radial diviſions of theſe circular ſpaces; the ſum of theſe, with half the central number, make alſo the ſame 180.

5. There are alſo included four ſets of other circular ſpaces, bounded by circles that are excentric with regard to the common centre; each of theſe ſets containing five ſpaces; and the centres of them being at A, B, C, D. For diſtinction, theſe circles are drawn with different marks, ſome dotted, others by ſhort unconnected lines, &c; or ſtill better with inks of divers colours, as blue, red, green, yellow.

Theſe ſets of excentric circular ſpaces interſect thoſe of the concentric, and each other; and yet, the numbers contained in each of the excentric ſpaces, taken all around through any of the 20, which are excentric, make the ſame ſum as thoſe in the concentric, namely 360, when the central number 12 is added. Their halves alſo, taken above or below the double horizontal line, with half the central number, make up 180.

It is obſervable, that there is not one of the numbers but what belongs at leaſt to two of the circular ſpaces; ſome to three, ſome to four, ſome to five: and yet they are all ſo placed, as never to break the required number 360, in any of the 28 circular ſpaces within the primitive circle. They have alſo other properties. See Franklin's Exp. and Obſ. pa. 350, edit. 4to, 1769; or Ferguſon's Tables and Tracts, 1771, pa. 318.

MAGICAL *Picture*, in Electricity, was firſt contrived by Mr. Kinnerſley, and is thus made: Having a large mezzotinto with a frame and glaſs, as of the king for inſtance, take out the print, and cut a pannel out of it, near two inches diſtant from the frame all around; then with thin paſte or gum-water, fix the border that is cut off on the inſide of the glaſs, preſſing it ſmooth and cloſe; then fill up the vacancy by gilding the glaſs well with leaf gold or braſs. Gild likewiſe the inner edge of the back of the frame all round, except the top part, and form a communication between that gilding and the gilding behind the glaſs; then put in the board, and that ſide is finiſhed. Next turn up the glaſs, and gild the foreſide exactly over the back gilding, and when it is dry, cover it by paſting on the pannel of the picture that has been cut out, obſerving to bring the correſponding parts of the border and picture together, by which means the picture will appear entire, as at firſt, only part behind the glaſs, and part before.

Hold the picture horizontally by the top, and place a ſmall moveable gilt crown on the king's head. If now the picture be moderately electrified, and another perſon take hold of the frame with one hand, ſo that his fingers touch its inſide gilding, and with the other hand endeavour to take off the crown, he will receive a violent blow, and fail in the attempt. If the picture were highly charged, the conſequence might be as fatal as that of high treaſon. The operator, who holds the picture by the upper end, where the inſide of the frame is not gilt, to prevent its falling, feels nothing of the ſhock, and may touch the face of the picture without danger. And if a ring of perſons take the ſhock among them, the experiment is called the conſpirators. See Franklin's Exper. and Obſerv. pa. 30.

MAGINI (John-Anthony), or Maginus, profeſſor of mathematics in the univerſity of Bologna, was born at Padua in the year 1536. Magini was remarkable for his great aſſiduity in acquiring and improving the knowledge of the mathematical ſciences, with ſeveral new inventions for theſe purpoſes, and for the extraordinary favour he obtained from moſt princes of his time. This doubtleſs aroſe partly from the celebrity he had in matters of aſtrology, to which he was greatly addicted, making horoſcopes, and foretelling events, both relating to perſons and things. He was invited by the emperor Rodolphus to come to Vienna, where he promiſed him a profeſſor's chair, about the year 1597; but not being able to prevail on him to ſettle there, he nevertheleſs gave him a handſome penſion.

It is ſaid, he was ſo much addicted to aſtrological predictions, that he not only foretold many good and evil events relative to others with ſucceſs; but even foretold his own death, which came to paſs the ſame year: all which he repreſented as under the influence of the ſtars. Tomaſini ſays, that Magini, being advanced to his 61ſt year, was ſtruck with an apoplexy, which ended his days; and that a long while before, he had told him and others, that he was afraid of that year. And Roſſeni, his pupil, ſays, that Magini died under an aſpect of the planets, which, according to his own prediction, would prove fatal to him; and he mentions Riccioli as affirming that he ſaid, the figure of his nativity, and his climacteric year, doomed him to die about that time; which happened in 1618, in the 62d year of his age.

His writings do honour to his memory, as they were very conſiderable, and upon learned ſubjects. The principal were the following: 1. His Ephemeris, in 3 volumes, from the year 1580 to 1630.—2. Tables of Secondary Motions.—3. Aſtronomical, Gnomonical, and Geographical Problems.—4. Theory of the Planets, according to Copernicus.—5. A Confutation of Scaliger's Diſſertation concerning the Preceſſion of the

Equinox.—6. A Primum Mobile, in 12 books.—7. A Treatiſe of Plane and Spherical Trigonometry.—8. A Commentary on Ptolomy's Geography.—9. A Chorographical Deſcription of the Regions and Cities of Italy, illuſtrated with 60 maps; with ſome other papers on Aſtrological ſubjects.

MAGNET, MAGNES, the *Loadſtone*; a kind of ferruginous ſtone, reſembling iron ore in weight and colour, though rather harder and heavier; and is endued with divers extraordinary properties, attractive, directive, inclinatory, &c. See MAGNETISM.

The Magnet is alſo called *Lapis Heracleus*, from Heraclea, a city of Magneſia, a port of the ancient Lydia, where it was ſaid it was firſt found, and from which it is uſually ſuppoſed that it took its name. Though ſome derive the word from a ſhepherd named *Magnes*, who firſt diſcovered it on Mount Ida with the iron of his crook. It is alſo called *Lapis Nauticus*, from its uſe in navigation; alſo *Siderites*, from its virtue in attracting iron, which the Greeks call σίδηρος.

The Magnet is uſually found in iron mines, and ſometimes in very large pieces, half magnet, half iron. Its colour is different, as found in different countries. Norman obſerves, that the beſt are thoſe brought from China and Bengal, which are of an irony or ſanguine colour; thoſe of Arabia are reddiſh; thoſe of Macedonia, blackiſh; and thoſe of Hungary, Germany, England, &c, the colour of unwrought iron. Neither its figure nor bulk are conſtant or determined; being found of all ſhapes and ſizes.

The Ancients reckoned five kinds of Magnets, different in colour and virtue: the Ethiopic, Magneſian, Bœotic, Alexandrian, and Natolian. They alſo took it to be male and female: but the chief uſe they made of it was in medicine; eſpecially for the cure of burns and defluxions of the eyes.—The Moderns, more happy, take it to conduct them in their voyages.

The moſt diſtinguiſhing properties of the Magnet are, That it attracts iron, and that it points towards the poles of the world; and in other circumſtances alſo dips or inclines to a point beneath the horizon, directly under the pole; it alſo communicates theſe properties, by touch, to iron. By means of which, are obtained the mariner's needles, both horizontal, and inclinatory or dipping needles.

The Attractive Power of the MAGNET, was known to the Ancients, and is mentioned even by Plato and Euripides, who call it the *Herculean ſtone*, becauſe it commands iron, which ſubdues every thing elſe: but the knowledge of its directive power, by which it diſpoſes its poles along the meridian of every place, or nearly ſo, and cauſes needles, pieces of iron, &c, touched with it, to point nearly north and ſouth, is of a much later date; though the diſcoverer himſelf, and the exact time of the diſcovery, be not now known. The firſt mention of it is about 1260, when it has been ſaid that Marco Polo, a Venetian, introduced the mariner's compaſs; though not as an invention of his own, but as derived from the Chineſe, who it ſeems had the uſe of it long before; though ſome imagine that the Chineſe rather borrowed it from the Europeans.

But Flavio de Gira, a Neapolitan, who lived in the 13th century, is the perſon uſually ſuppoſed to have the beſt title to the diſcovery; and yet Sir G. Wheeler mentions, that he had ſeen a book of aſtronomy much older, which ſuppoſed the uſe of the needle; though not as applied to the purpoſes of navigation, but of aſtronomy. And in Guiot de Provins, an old French poet, who wrote about the year 1180, there is an expreſs mention made of the loadſtone and the compaſs; and their uſe in navigation obliquely hinted at.

The Variation of the MAGNET, or needle, or its deviation from the pole, was firſt diſcovered by Sebaſtian Cabot, a Venetian, in 1500; and the variation of that variation, or change in its direction, by Mr. Henry Gellibrand, profeſſor of aſtronomy in Greſham college, about the year 1625.

Laſtly, the Dip or inclination of the needle, when at liberty to play vertically, to a point beneath the horizon, was firſt diſcovered by another of our countrymen, Mr. Robert Norman, about the year 1576.

The Phenomena of the MAGNET, are as follow: 1, In every Magnet there are two poles, of which the one points northwards, the other ſouthwards; and if the Magnet be divided into ever ſo many pieces, the two poles will be found in each piece. The poles of a Magnet may be found by holding a very fine ſhort needle over it; for where the poles are, the needle will ſtand upright, but no where elſe.—2, Theſe poles, in different parts of the globe, are differently inclined towards a point under the horizon.—3, Theſe poles, though contrary to each other, do help mutually towards the Magnet's attraction, and ſuſpenſion of iron.—4, If two Magnets be ſpherical, one will turn or conform itſelf to the other, ſo as either of them would do to the earth; and after they have ſo conformed or turned themſelves, they endeavour to approach or join each other; but if placed in a contrary poſition, they avoid each other.—5, If a Magnet be cut through the axis, the ſegments or parts of the ſtone, which before were joined, will now avoid and fly each other.—6, If the Magnet be cut perpendicular to its axis, the two points, which before were conjoined, will become contrary poles; one in the one, and one in the other ſegment.—7, Iron receives virtue from the Magnet by application to it, or barely from an approach near it, though it do not touch it; and the iron receives this virtue variouſly, according to the parts of the ſtone it is made to touch, or even approach to.—8, If an oblong piece of iron be anyhow applied to the ſtone, it receives virtue from it only lengthways.—9, The Magnet loſes none of its own virtue by communicating any to the iron; and this virtue it can communicate to the iron very ſpeedily: though the longer the iron joins or touches the ſtone, the longer will its communicated virtue hold; and a better Magnet will communicate more of it, and ſooner, than one not ſo good.—10, Steel receives virtue from the Magnet better than iron.—11, A needle touched by a Magnet will turn its ends the ſame way towards the poles of the world, as the Magnet itſelf does.—12, Neither loadſtone nor needles touched by it do conform their poles exactly to thoſe of the world, but have uſually ſome variation from them: and this variation is different in divers places, and at divers times in the ſame places.—13, A loadſtone will take up much more iron when armed, or capped, than it can alone. (A loadſtone is ſaid to be armed, when its poles are ſurrounded with

plates

plates of ſteel: and to determine the quantity of ſteel to be applied, try the Magnet with ſeveral ſteel bars; and the greateſt weight it takes up, with a bar on, is to be the weight of its armour.) And though an iron ring or key be ſuſpended by the loadſtone, yet this does not hinder the ring or key from turning round any way, either to the right or left.—14, The force of a loadſtone may be variouſly increaſed or leſſened by variouſly applying to it, either iron, or another loadſtone.—15, A ſtrong Magnet at the leaſt diſtance from a ſmaller or a weaker, cannot draw to it a piece of iron adhering actually to ſuch ſmaller or weaker ſtone; but if it come to touch it, it can draw it from the other: but a weaker Magnet, or even a ſmall piece of iron, can draw away or ſeparate a piece of iron contiguous to a larger or ſtronger Magnet.—16, In theſe northern parts of the world, the ſouth pole of a Magnet will raiſe up more iron than its north pole.—17, A plate of iron only, but no other body interpoſed, can impede the operation of the loadſtone, either as to its attractive or directive quality.—18, The power or virtue of a loadſtone may be impaired by lying long in a wrong poſition, as alſo by ruſt, wet, &c; and may be quite deſtroyed by fire, lightning, &c.—19, A piece of iron wire well touched, upon being bent round in a ring, or coiled round on a ſtick, &c, will always have its directive virtue diminiſhed, and often quite deſtroyed. And yet if the whole length of the wire were not entirely bent, ſo that the ends of it, though but for the length of one-tenth of an inch, were left ſtraight, the virtue will not be deſtroyed in thoſe parts; though it will in all the reſt.—20, The ſphere of activity of Magnets is greater and leſs at different times. Alſo, the variation of the needle from the meridian, is various at different times of the day.—21, By twiſting a piece of wire touched with a Magnet, its virtue is greatly diminiſhed; and ſometimes ſo diſordered and confuſed, that in ſome parts it will attract, and in others repel; and even, in ſome places, one ſide of the wire ſeems to be attracted, and the other ſide repelled, by one and the ſame pole of the ſtone.—22, A piece of wire that has been touched, on being ſplit, or cleft in two, the poles are ſometimes changed, as in a cleft Magnet; the north pole becoming the ſouth, and the ſouth the north: and yet ſometimes one half of the wire will retain its former poles, and the other half will have them changed. —23, A wire being touched from end to end with one pole of a Magnet, the end at which you begin will always turn contrary to the pole that touched it: and if it be again touched the ſame way with the other pole of the Magnet, it will then be turned the contrary way.—24, If a piece of wire be touched in the middle with only one pole of the Magnet, without moving it backwards or forwards; in that place will be the pole of the wire, and the two ends will be the other pole.—25, If a Magnet be heated red hot, and again cooled either with its ſouth pole towards the north in a horizontal poſition, or with its ſouth pole downwards in a perpendicular poſition, its poles will be changed. —26, Mr. Boyle (to whom we are indebted for the following magnetical phenomena) found he could preſently change the poles of a ſmall fragment of a loadſtone, by applying them to the oppoſite vigorous poles of a large one.—27, Hard iron tools well tempered, when heated by a briſk attrition, as filing, turning, &c, will attract thin filings or chips of iron, ſteel, &c; and hence we obſerve that files, punches, augres, &c, have a ſmall degree of magnetic virtue.—28, The iron bars of windows, &c, which have ſtood a long time in an erect poſition, grow permanently magnetical; the lower ends of ſuch bars being the north pole, and the upper end the ſouth pole.—29, A bar of iron that has not ſtood long in an erect poſture, if it be only held perpendicularly, will become magnetical, and its lower end the north pole, as appears from its attracting the ſouth pole of a needle: but then this virtue is tranſient, and by inverting the bar, the poles change their places. In order therefore to render the quality permanent in an iron bar, it muſt continue a long time in a proper poſition. But fire will produce the effect in a ſhort time: for as it will immediately deprive a loadſtone of its attractive virtue; ſo it ſoon gives a verticity to a bar of iron, if, being heated red hot, it be cooled in an erect poſture, or directly north and ſouth. Even tongs and fireforks, by being often heated, and ſet to cool again in a poſture nearly erect, have gained this magnetic property. Sometimes iron bars, by long ſtanding in a perpendicular poſition, have acquired the magnetic virtue in a ſurpriſing degree. A bar about 10 feet long, and three inches thick, ſupporting the ſummer beam of a room, was able to turn the needle at 8 or 10 feet diſtance, and exceeded a loadſtone of $3\frac{1}{2}$ pounds weight: from the middle point upwards it was a north pole, and downwards a ſouth pole. And Mr. Martin mentions a bar, which had been the beam of a large ſteel-yard that had ſeveral poles in it.—30, Mr. Boyle found, that by heating a piece of Engliſh oker red-hot, and placing it to cool in a proper poſture, it manifeſtly acquired a magnetic virtue. And an excellent Magnet, belonging to the ſame ingenious gentleman, having lain near a year in an inconvenient poſture, had its virtue greatly impaired, as if it had been by fire.—31, A needle well touched, it is known, will point north and ſouth: if it have one contrary touch of the ſame ſtone, it will be deprived of its faculty; and by another ſuch touch, it will have its poles interchanged.—32, If an iron bar have gained a verticity by being heated red-hot and cooled again, north and ſouth, and then hammered at the two ends; its virtue will be deſtroyed by two or three ſmart blows on the middle.—33, By drawing the back of a knife, or a long piece of ſteel-wire, &c, leiſurely over the pole of a loadſtone, carrying the motion from the middle of the ſtone to the pole; the knife or wire will attract one end of a needle; but if the knife or wire be paſſed from the ſaid pole to the middle of the ſtone, it will repel the ſame end of the needle.—34, Either a Magnet or a piece of iron being laid on a piece of cork, ſo as to float freely on water; it will be found, that, whichſoever of the two is held in the hand, the other will be drawn to it: ſo that iron attracts the Magnet as much as it is attracted by it; action and re-action being always equal. In this experiment, if the Magnet be ſet afloat, it will direct its two poles to the poles of the world nearly.—35, A knife &c touched with a Magnet, acquires a greater or leſs degree of virtue, according to the part it is touched on. It receives the ſtrongeſt virtue, when it is drawn leiſurely from the handle

handle towards the point over one of the poles. And if the ſame knife thus touched, and thus poſſeſſed of a ſtrong attractive power, be retouched in a contrary direction, viz, by drawing it from the point towards the handle over the ſame pole, it immediately loſes all its virtue.—36, A Magnet acts with equal force in vacuo as in the open air.—37, The ſmalleſt Magnets have uſually the greateſt power in proportion to their bulk. A large Magnet will ſeldom take up above 3 or 4 times its own weight, while a ſmall one will often take up more than ten times its weight. A Magnet worn by Sir Iſaac Newton in a ring, and which weighed only 3 grains, would take up 746 grains, or almoſt 250 times its own weight. A magnetic bar made by Mr. Canton, weighing 10 oz. 12 dwts, took up more than 79 ounces; and a flat ſemicircular ſteel Magnet, weighing 1 oz. 13 dwts, took up an iron wedge of 90 ounces.

Armed MAGNET, denotes one that is capped, caſed, or ſet in iron or ſteel, to make it take up a greater weight, and alſo more readily to diſtinguiſh its poles. For the methods of doing this, ſee Mr. Michell's book on this ſubject.

Artificial MAGNET, is a bar of iron or ſteel, impregnated with the magnetic virtue, ſo as to poſſeſs all the properties of the natural loadſtone, and be uſed inſtead of it. How to make Magnets of this kind, by means of a natural Magnet, and even without the aſſiſtance of any Magnet, was ſuggeſted many years ſince by Mr. Savary, and particularly deſcribed in the Philoſ. Tranſ. number 414. See alſo Abridgment, vol. 6, pa. 260. But as his method was tedious and operoſe, though capable of communicating a very conſiderable virtue, it was little practiſed. Dr. Gowin Knight firſt brought this kind of Magnets to their preſent ſtate of perfection, ſo as to be even of much greater efficacy than the natural ones. But as he refuſed to diſcover his methods upon any terms whatever (even, as he ſaid, though he ſhould receive in return as many guineas as he could carry), theſe curious and valuable ſecrets in a great meaſure died with him. The reſult of his method however was firſt publiſhed in the Philoſ. Tranſ. for 1744, art. 8, and for 1745, art. 3. See alſo the vol. for 1747, art. 2. And in the 69th vol. Mr. Benjamin Wilſon has given a proceſs, which at leaſt diſcovers one of the leading principles of Dr. Knight's art. The method, according to Mr. Wilſon, was as follows. Having provided a great quantity of clean iron filings, he put them into a large tub that was more than one-third filled with clean water; he then, with great labour, ſhook the tub to and fro for many hours together, that the friction between the grains of iron, by this treatment, might break or rub off ſuch ſmall parts as would remain ſuſpended in the water for ſome time. The water being thus rendered very muddy, he poured it into a clean iron veſſel, leaving the filings behind; and when the water had ſtood long enough to become clear, he poured it out carefully, without diſturbing ſuch of the ſediment as ſtill remained, which now appeared reduced almoſt to impalpable powder. This powder was afterwards removed into another veſſel, to dry it. Having, by ſeveral repetitions of this proceſs, procured a ſufficient quantity of this very fine powder, the next thing was to make a paſte of it, and that with ſome vehicle containing a good quantity of the phlogiſtic principle; for this purpoſe, he had recourſe to linſeed oil, in preference to all other fluids. With theſe two ingredients only, he made a ſtiff paſte, and took great care to knead it well before he moulded it into convenient ſhapes. Sometimes, while the paſte continued in its ſoft ſtate, he would put the impreſſion of a ſeal; one of which is in the Britiſh Muſeum. This paſte ſo moulded was then ſet upon wood, or a tile, to dry or bake it before a moderate fire, being placed at about one foot diſtance. He found that a moderate fire was moſt proper, becauſe a greater degree of heat would make the compoſition crack in many places. The time requiſite for the baking or drying of this paſte, was uſually about 5 or 6 hours, before it attained a ſufficient degree of hardneſs. When that was done, and the ſeveral baked pieces were become cold, he gave them their magnetic virtue in any direction he pleaſed, by placing them between the extreme ends of his large magazine of artificial magnets, for a few ſeconds. The virtue they acquired by this method was ſuch, that, when any of thoſe pieces were held between two of his beſt ten-guinea bars, with its poles purpoſely inverted, it immediately of itſelf turned about to recover its natural direction, which the force of thoſe very powerful bars was not ſufficient to counteract. Philoſ. Tranſ. vol. 65, for 1779.

Methods for artificial Magnets were alſo diſcovered and publiſhed by the Rev. Mr. John Michell, in a Treatiſe on Artificial Magnets, printed in 1750, and by Mr. John Canton, in the Philoſ. Tranſ. for 1751. The proceſs for the ſame purpoſe was alſo found out by other perſons, particularly by Du Hamel, Hiſt. Acad. Roy. 1745 and 1750, and by Marul Uitgeleeze Natuurkund. Verhand. tom. 2, p. 261.

Mr. Canton's method is as follows: Procure a dozen of bars; 6 of ſoft ſteel, and 6 of hard; the former to be each 3 inches long, a quarter of an inch broad, and 1-20th of an inch thick; with two pieces of iron, each half the length of one of the bars, but of the ſame breadth and thickneſs; and the 6 hard bars to be each 5½ inches long, half an inch broad, and 3-20ths of an inch thick, with two pieces of iron of half the length, but the whole breadth and thickneſs of one of the hard bars; and let all the bars be marked with a line quite around them at one end. Then take an iron poker and tongs (fig. 1, plate 16), or two bars of iron, the larger they are, and the longer they have been uſed, the better; and fixing the poker upright between the knees, hold to it, near the top, one of the ſoft bars, having its marked end downwards by a piece of ſewing ſilk, which muſt be pulled tight by the left hand, that the bar may not ſlide: then graſping the tongs with the right hand, a little below the middle, and holding them nearly in a vertical poſition, let the bar be ſtroked by the lower end, from the bottom to the top, about ten times on each ſide, which will give it a magnetic power ſufficient to lift a ſmall key at the marked end: which end, if the bar were ſuſpended on a point, would turn towards the north, and is therefore called the north pole; and the unmarked end is, for the ſame reaſon, called

called the ſouth pole. Four of the ſoft bars being impregnated after this manner, lay the two (fig. 2) parallel to each other, at a quarter of an inch diſtance, between the two pieces of iron belonging to them, a north and a ſouth pole againſt each piece of iron: then take two of the four bars already made magnetical, and place them together ſo as to make a double bar in thickneſs, the north pole of one even with the ſouth pole of the other; and the remaining two being put to theſe, one on each ſide, ſo as to have two north and two ſouth poles together, ſeparate the north from the ſouth poles at one end by a large pin, and place them perpendicularly with that end downward on the middle of one of the parallel bars, the two north poles towards its ſouth end, and the two ſouth poles towards its north end: ſlide them three or four times backward and forward the whole length of the bar; then removing them from the middle of this bar, place them on the middle of the other bar as before directed, and go over that in the ſame manner; then turn both the bars the other ſide upwards, and repeat the former operation: this being done, take the two from between the pieces of iron; and, placing the two outermoſt of the touching bars in their ſtead, let the other two be the outermoſt of the four to touch theſe with; and this proceſs being repeated till each pair of bars have been touched three or four times over, which will give them a conſiderable magnetic power. Put the half-dozen together after the manner of the four (fig. 3), and touch them with two pair of the hard bars placed between their irons, at the diſtance of about half an inch from each other; then lay the ſoft bars aſide, and with the four hard ones let the other two be impregnated (fig. 4), holding the touching bars apart at the lower end near two-tenths of an inch; to which diſtance let them be ſeparated after they are ſet on the parallel bar, and brought together again before they are taken off: this being obſerved, proceed according to the method deſcribed above, till each pair have been touched two or three times over. But as this vertical way of touching a bar, will not give it quite ſo much of the magnetic virtue as it will receive, let each pair be now touched once or twice over in their parallel poſition between the irons (fig. 5), with two of the bars held horizontally, or nearly ſo, by drawing at the ſame time the north end of one from the middle over the ſouth end, and the ſouth of the other from the middle over the north end of a parallel bar; then bringing them to the middle again, without touching the parallel bar, give three or four of theſe horizontal ſtrokes to each ſide. The horizontal touch, after the vertical, will make the bars as ſtrong as they poſſibly can be made, as appears by their not receiving any additional ſtrength, when the vertical touch is given by a great number of bars, and the horizontal by thoſe of a ſuperior magnetic power.

This whole proceſs may be gone through in about half an hour; and each of the large bars, if well hardened, may be made to lift 28 Troy ounces, and ſometimes more. And when theſe bars are thus impregnated, they will give to a hard bar of the ſame ſize its full virtue in leſs than two minutes; and therefore will anſwer all the purpoſes of Magnetiſm in navigation and experimental philoſophy, much better than the loadſtone, which has not a power ſufficient to impregnate hard bars. The half dozen being put into a caſe (fig. 6), in ſuch a manner as that no two poles of the ſame name may be together, and their irons with them as one bar, they will retain the virtues they have received; but if their power ſhould, by making experiments, be ever ſo far impaired, it may be reſtored without any foreign aſſiſtance in a few minutes. And if, perchance, a much larger ſet of bars ſhould be required, theſe will communicate to them a ſufficient power to proceed with; and they may, in a ſhort time, by the ſame method, be brought to their full ſtrength.

MAGNETISM, the quality or conſtitution of a body, by which it is rendered magnetical, or a magnet, ſenſibly attracting iron, and giving it a meridional direction.

This is a tranſient power, capable of being produced, deſtroyed, or reſtored.

The Laws of MAGNETISM.

Theſe laws are laid down by Mr. Whiſton in the following propoſitions.——1, The Loadſtone has both an attractive and a directive power united together, while iron touched by it has only the former; i. e. the magnet not only attracts needles, or ſteel filings, but alſo directs them to certain different angles, with reſpect to its own ſurface and axis; whereas iron, touched with it, does little or nothing more than attract them; ſtill ſuffering them to lie along or ſtand perpendicular to its ſurface and edges in all places, without any ſuch ſpecial direction.

2. Neither the ſtrongeſt nor the largeſt magnets give a better directive touch to needles, than thoſe of a leſs ſize or virtue: to which may be added, that whereas there are two qualities in all magnets, an attractive and a directive one; neither of them depend on, or are any argument of the ſtrength of the other.

3. The attractive power of magnets, and of iron, will greatly increaſe or diminiſh the weight of needles on the balance; nay, it will overcome that weight, and even ſuſtain ſome other additional alſo: while the directive power has a much ſmaller effect. Gaſſendus indeed, as well as Merſennus and Gilbert, aſſert that it has none at all: but by miſtake; for Whiſton found, from repeated trials on large needles, that after the touch they weighed leſs than before. One of 4584$\frac{1}{8}$ grains, loſt 2$\frac{5}{8}$ grains by the touch; and another of 65726 grains weight, no leſs than 14 grains.

4. It is probable that iron conſiſts almoſt wholly of the attractive particles; and the magnet, of the attractive and directive together; mixed, probably, with other heterogeneous matter; as having never been purged by the fire, which iron has; and hence may ariſe the reaſon why iron, after it has been touched, will lift up a much greater weight than the loadſtone that touched it.

5. The quantity and direction of magnetic powers, communicated to needles, are not properly, after ſuch communication, owing to the magnet which gave the touch; but to the goodneſs of the ſteel that receives it, and to the ſtrength and poſition of the terreſtrial loadſtone, whoſe influence alone thoſe needles are afterwards ſubject to, and directed by: ſo that all ſuch needles, if good, move with the ſame ſtrength, and point to the ſame angle, whatever loadſtone they may have been excited by, provided it be but a good one. Nor does it

ſeem that the touch does much more in magnetical caſes, than attrition does in electrical ones; i. e. ſerving to rub off ſome obſtructing particles, that adhere to the ſurface of the ſteel, and opening the pores of the body touched, and ſo make way for the entrance and exit of ſuch effluvia as occaſion or aſſiſt the powers we are ſpeaking of. Hence Mr. Whiſton takes occaſion to obſerve, that the directive power of the loadſtone ſeems to be mechanical, and to be derived from magnetic effluvia, circulating continually round it.

6. The abſolute attractive power of different armed loadſtones, is, *cæteris paribus*, not according to either the diameters or ſolidities of the loadſtones, but according to the quantity of their ſurfaces, or in the duplicate proportion of their diameters.

7. The power of good magnets unarmed, ſenſibly equal in ſtrength, ſimilar in figure and poſition, but unequal in magnitude, is ſometimes a little greater, ſometimes a little leſs, than in the proportion of their ſimilar diameters.

8. The loadſtone attracts needles that have been touched, and others that have not been touched, with equal force at diſtances unequal, viz, when the diſtance of the former is to the diſtance of the latter, as 5 to 2.

9. Both poles of a magnet equally attract needles, till they are touched; then it is, and then only, that one pole begins to attract one end, and repel the other: though the repelling pole will ſtill attract upon contact, and even at very ſmall diſtances.

10. The attractive power of loadſtones, in their ſimilar poſition to, but different diſtances from, magnetic needles, is in the ſeſquiduplicate proportion of the diſtances of their ſurfaces from their needles reciprocally; or as the mean proportionals between the ſquares and the cubes of thoſe diſtances reciprocally; or as the ſquare roots of the 5th powers of thoſe diſtances reciprocally. Thus, the magnetic force of attraction, at twice the diſtance from the ſurface of the loadſtone, is between a 5th and 6th part of the force at the firſt diſtance; at thrice the diſtance, the force is between the 15th and 16th part; at four times the diſtance, the power is the 32d part of the firſt; and at ſix times the diſtance, it is the 88th part. Where it is to be noted, that the diſtances are not counted from the centre, as in the laws of gravity, but from the ſurface: all experience aſſuring us, that the magnetic power reſides chiefly, if not wholly, in the ſurfaces of the loadſtone and iron; without any particular relation to any centre at all. The proportion here laid down was determined by Mr. Whiſton, from a great number of experiments by Mr. Hawkſbee, Dr. Brook Taylor, and himſelf; meaſuring the force by the chords of thoſe arcs by which the magnet at ſeveral diſtances draws the needle out of its natural direction, to which chords, as he demonſtrates, it is always proportional. The numbers in ſome of their moſt accurate trials, he gives in the following Table, ſetting down the half chords, or the ſines of half thoſe arcs of declination, as the true meaſures of the force of magnetic attraction.

Diſtances in inches.	*Degrees of inclination.*	*Sines of ½ arcs.*	*Seſquiduplicate ratio.*
20	2	175	466
14⅝	4	349	216
13⅝	6	523	170
12⅝	8	697	138
11⅝	10	871	105
10½	12	1045	87
9¼	14	1219	70

Other perſons however have found ſome variations in the proportions of magnetic force with reſpect to diſtance: Thus, Newton ſuppoſes it to decreaſe nearly in the triplicate ratio of the diſtance: Mr. Martin obſerves, that the power of his loadſtone decreaſes in the ſeſquiduplicate ratio of the diſtances inverſely: but Dr. Helſham and Mr. Michell found it to be as the ſquare of the diſtance inverſely; while others, as Dr. Brook Taylor and M. Muſchenbroek, are of opinion, that this power follows no certain ratio at all, and that the variation is different in different ſtones.

11. An inclinatory, or dipping-needle, of 6 inches radius, and of a priſmatic or cylindric figure, when it oſcillates along the magnetic meridian, performs there every mean vibration in about 6″ or 360‴, and every ſmall oſcillation in about 5″½, or 330‴: and the ſame kind of needle, 4 feet long, makes every mean oſcillation in about 24″, and every ſmall one in about 22″.

12. The whole power of Magnetiſm in this country, as it affects needles a foot long, is to that of gravity nearly as 1 to 300; and as it affects needles 4 feet long, as 1 to 600.

13. The quantity of magnetic power accelerating the ſame dipping-needle, as it oſcillates in different vertical planes, is always as the coſines of the angles made by thoſe planes with the magnetic meridian, taken on the horizon.

Thus, in eſtimating the quantity of force in the horizontal and in the vertical ſituations of needles at London, it is found that the latter, in needles of a foot long, is to the whole force along the magnetic meridian, as 96 to 100; and in needles 4 feet long, as 9667 to 10000: whereas, in the former, the whole force in needles of a foot long, is as 28 to 100; and in thoſe of 4 feet long, as 256 to 1000. Whence it follows, that the power by which horizontal needles are governed in theſe parts of the world, is but the quarter of the power by which the dipping-needle is moved.

Hence alſo, as the horizontal needle is moved only by a part of the power that moves the dipping-needle; and as it only points to a certain place in the horizon, becauſe that place is the neareſt to its original tendency of any that its ſituation will allow it to tend to; whenever the dipping-needle ſtands exactly perpendicular to the horizon, the horizontal needle will not reſpect one point of the compaſs more than another, but will wheel about any way uncertainly.

14. The time of oſcillation and vibration, both in dipping and horizontal needles, that are equally good, is as their length directly; and the actual velocities of their points along their arcs, are always unequal. And hence, magnetical needles are, *cæteris paribus*, ſtill better, the longer they are; and that in the ſame proportion with their lengths.

Of the Cauſes of MAGNETISM. Though many authors have propoſed hypotheſes, or written concerning the cauſe of Magnetiſm, as Plutarch, Deſcartes, Boyle, Newton, Gilbert, Hartſoeker, Halley, Whiſton, Knight, Beccaria, &c; nothing however has yet appeared that can be called a ſatisfactory ſolution of its phenomena. It is certain indeed, that both natural and artificial electricity will give polarity to needles, and even reverſe their poles; but though from this it may appear probable that the electric fluid is alſo the cauſe of Magnetiſm, yet in what manner the fluid acts while producing the magnetical phenomena, ſeems to be quite unknown.

Dr. Knight indeed deduces from ſeveral experiments the following propoſitions, which he offers, not ſo much to explain the nature of the cauſe of Magnetiſm, as the manner in which it acts: the magnetic matter of a loadſtone, he ſays, moves in a ſtream from one pole to the other internally, and is then carried back in a curve line externally, till it arrive again at the pole where it firſt entered, to be again admitted: the immediate cauſe why two or more magnetical bodies attract each other, is the flux of one and the ſame ſtream of magnetical matter through them; and the immediate cauſe of magnetic repulſion, is the conflux and accumulation of the magnetic matter. Philoſ. Tranſ. vol. 44, pa. 665.

Mr. Michell rejects the motion of a ſubtle fluid; but though he propoſed to publiſh a theory of Magnetiſm eſtabliſhed by experiments, no ſuch theory has appeared.

Signor Beccaria, from obſerving that a ſudden ſtroke of lightning gives polarity to Magnets, conjectures, that a regular and conſtant circulation of the whole maſs of the electric fluid from north to ſouth may be the original cauſe of Magnetiſm in general. This current he would not ſuppoſe to ariſe from one ſource, but from ſeveral, in the northern hemiſphere of the earth: the aberration of the common centre of all the currents from the north point, may be the cauſe of the variation of the needle; the period of this declination of the centre of the currents, may be the period of the variation; and the obliquity with which the currents ſtrike into the earth, may be the cauſe of the dipping of the needle, and alſo why bars of iron more eaſily receive the magnetic virtue in one particular direction. Lettre dell' Elettricismo, pa. 269; or Prieſtley's Hiſt. Elec. vol. 1, pa. 409. See alſo Cavallo's Treatiſe on Magnetiſm.

MAGNIFYING, is the making of objects appear larger than they uſually and naturally appear to the eye; whence convex lenſes, which have the power of doing this, are called Magnifying Glaſſes.

The Magnifying power of denſe mediums of certain figures, was known to the Ancients; though they were far from underſtanding the cauſe of this effect. Seneca ſays, that ſmall and obſcure letters appear larger and brighter through a glaſs globe filled with water; and he abſurdly accounts for it by ſaying, that the eye ſlides in the water, and cannot lay hold of its object. And Alexander Aphrodiſenſis, about two centuries after Seneca, ſays, that the reaſon why apples appear large when immerſed in water, is, that the water which is contiguous to any body is affected with the ſame quality and colour; ſo that the eye is deceived in imagining the body itſelf larger. But the firſt diſtinct account we have of the Magnifying power of glaſſes, is in the 12th century, in the writings of Roger Bacon, and Alhazen; and it is not improbable that from their obſervations the conſtruction of ſpectacles was derived. In the Opus Majus of Bacon, it is demonſtrated, that if a tranſparent body, interſperſed between the eye and an object, be convex towards the eye, the object will appear magnified.

MAGNIFYING *Glaſs*, in Optics, is a ſmall ſpherical convex lens; which, in tranſmitting the rays of light, inflects them more towards the axis, and ſo exhibits objects viewed through them larger than when viewed by the naked eye. See MICROSCOPE.

MAGNITUDE, any thing made up of parts locally extended, or continued; or that has ſeveral dimenſions; as a line, ſurface, ſolid, &c. Quantity is often uſed as ſynonymous with Magnitude. See QUANTITY.

Geometrical MAGNITUDES, are uſually, and moſt properly, conſidered as generated or produced by motion; as lines by the motion of points, ſurfaces by the motion of lines, and ſolids by the motion of ſurfaces.

Apparent MAGNITUDE, is that which is meaſured by the optic or viſual angle, intercepted between rays drawn from its extremes to the centre of the pupil of the eye. It is a fundamental maxim in optics, that whatever things are ſeen under the ſame or equal angles, appear equal; and vice verſa.—The apparent Magnitudes of an object at different diſtances, are in a ratio leſs than that of their diſtances reciprocally.

The apparent Magnitudes of the two great luminaries, the ſun and moon, at riſing and ſetting, are a phenomenon that has greatly embarraſſed the modern philoſophers. According to the ordinary laws of viſion, they ſhould appear the leaſt when neareſt the horizon, being then fartheſt from the eye; and yet it is found that the contrary is true in fact. Thus, it is well known that the mean apparent diameter of the moon, at her greateſt height in the meridian, is nearly 31′ in round numbers, ſubtending then an angle of that quantity as meaſured by any inſtrument. But, being viewed when ſhe riſes or ſets, ſhe ſeems to the eye as two or three times as large as before; and yet when meaſured by the inſtrument, her diameter is not found increaſed at all.

Ptolomy, in his Almageſt, lib. 1, cap. 3, taking for granted, that the angle ſubtended by the moon was really increaſed, aſcribed the increaſe to a refraction of the rays by vapours, which actually enlarge the angle under which the moon appears; juſt as the angle is enlarged by which an object is ſeen from under water: and his commentator Theon explains diſtinctly how the dilatation of the angle in the object immerſed in water is cauſed. But it being afterwards diſcovered, that there is no alteration in the angle, another ſolution was ſtarted by the Arab Alhazen, which was followed and improved by Bacon, Vitello, Kepler, Peckham, and others. According to Alhazen, the ſight apprehends the ſurface of the heavens as flat, and judges of the ſtars as it would of ordinary viſible objects extended upon a wide plain; the eye ſees then under equal angles indeed, but withal perceives a difference in their

diſtances, and (on account of the ſemidiameter of the earth, which is interpoſed in one caſe, and not in the other) it is hence induced to judge thoſe that appear more remote to be greater. Some farther improvement was made in this explanation by Mr. Hobbes, though he fell into ſome miſtakes in his application of geometry to this ſubject: for he obſerves, that this deception operates gradually from the zenith to the horizon; and that if the apparent arch of the ſky be divided into any number of equal parts, thoſe parts, in deſcending towards the horizon, will ſubtend an angle that is gradually leſs and leſs. And he was the firſt who expreſsly conſidered the vaulted appearance of the ſky as a real portion of a circle.

Des Cartes, and from him Dr. Wallis, and moſt other authors, account for the appearance of a different diſtance under the ſame angle, from the long ſeries of objects interpoſed between the eye and the extremity of the ſenſible horizon; which makes us imagine it more remote than when in the meridian, where the eye ſees nothing in the way between the object and itſelf. This idea of a great diſtance makes us imagine the luminary the larger; for an object being ſeen under any certain angle, and believed at the ſame time very remote, we naturally judge it muſt be very large, to appear under ſuch an angle at ſuch a diſtance. And thus a pure judgment of the mind makes us ſee the ſun, or the moon, larger in the horizon than in the meridian; notwithſtanding their diameters meaſured by any inſtrument are really leſs in the former ſituation than the latter.

James Gregory, in his Geom. Pars Univerſalis, pa. 141, ſubſcribes to this opinion: Father Mallebranche alſo, in the firſt book of his Recherche de la Verité, has explained this phenomenon almoſt in the expreſſion of Des Cartes: and Huygens, in his Treatiſe on the Parhelia, tranſlated by Dr. Smith, Optics, art. 536, has approved, and very clearly illuſtrated, the received opinion. The cauſe of this fallacy, ſays he, in ſhort, is this; that we think the ſun, or any thing elſe in the heavens, farther from us when it is near the horizon, than when it approaches towards the vertex, becauſe we imagine every thing in the air that appears near the vertex to be farther from us than the clouds that fly over our heads; whereas, on the other hand, we are uſed to obſerve a large extent of land lying between us and the objects near the horizon, at the farther end of which the convexity of the ſky begins to appear; which therefore, with the objects that appear in it, are uſually imagined to be much farther from us. Now when two objects of equal magnitude appear under the ſame angle, we always judge that object to be larger which we think is remoter. And this, according to them, is the true cauſe of the deception in queſtion. It is really aſtoniſhing that an hypotheſis ſo palpably falſe ſhould ever be held and maintained by ſuch eminent men; for it is daily ſeen that the moon or ſun, when near the horizon, very ſuddenly change their magnitude, as they aſcend or deſcend, though all the intervening objects are ſeen juſt as before; and that the luminary appears largeſt of all when feweſt objects appear on the earth, as in a thick fog or miſt. It is no wonder therefore that other reaſons have been aſſigned for this remarkable phenomenon.

Accordingly Gaſſendus was of opinion, that this effect ariſes from hence; that the pupil of the eye, being always more open as the place is more dark, as in the morning and evening, when the light is leſs, and beſides the earth being then covered with groſs vapours, through a longer column of which the rays muſt paſs to reach the horizon; the image of the luminary enters the eye at a greater angle, and is really painted there larger than when the luminary is higher. See APPARENT *Diameter* and *Magnitude*.

F. Gouge advances another hypotheſis, which is, that when the luminaries are in the horizon, the proximity of the earth, and the groſs vapours with which they then appear enveloped, have the ſame effect with regard to us, as a wall, or other denſe body, placed behind a column; which in that caſe appears larger than when inſulated, and encompaſſed on all ſides with an illuminated air.

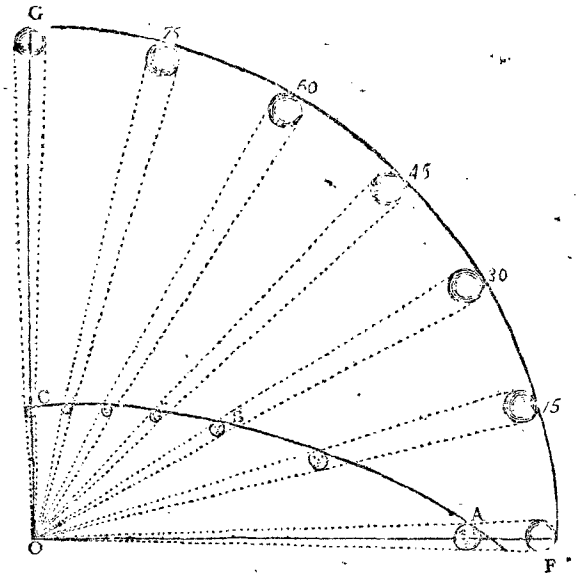
The commonly received opinion has been diſputed, not only by F. Gouge, who obſerves, Acad. Sci. 1700, pa. 11, that the horizontal moon appears equally large acroſs the ſea, where there are no objects to produce the effect aſcribed to them; but alſo by Mr. Molyneux, who ſays, Philoſ. Tranſ. abr. vol. 1, pa. 221, that if this hypotheſis be true, we may at any time increaſe the apparent magnitude of the moon, even in the meridian; for, in order to divide the ſpace between it and the eye, we need only to look at it behind a cluſter of chimneys, the ridge of a hill, or the top of a houſe, &c. He makes alſo the ſame obſervation with F. Gouge, above mentioned, and farther obſerves, that when the height of all the intermediate objects is cut off; by looking through a tube, the imagination is not helped, and yet the moon ſeems ſtill as large as before. However, Mr. Molyneux advances no hypotheſis of his own.

Biſhop Berkley ſuppoſed, that the moon appears larger near the horizon, becauſe ſhe then appears fainter, and her beams affect the eye leſs. And Mr. Robins has recited ſome other opinions on this ſubject, Math. Tracts, vol. 2, pa. 242.

Dr. Deſaguliers has illuſtrated the doctrine of the horizontal moon, Philoſ. Tranſ. abr. vol. 8, pa. 130, upon the ſuppoſition of our imagining the viſible heavens to be only a ſmall portion of a ſpherical ſurface, and conſequently ſuppoſing the moon to be farther from us in the horizon than near the zenith; and by ſeveral ingenious contrivances he demonſtrated how liable we are to ſuch deceptions. The ſame idea is purſued ſtill farther by Dr. Smith, in his Optics, where he determines that the centre of the apparent ſpherical ſegment of the ſky lying much below the eye, or the horizon, the apparent diſtance of its parts near the horizon was about 3 or 4 times greater than the apparent diſtance of its parts over head; from which reaſon it is, he infers, that the moon always appears the larger as ſhe is lower, and alſo that we always think the height of a celeſtial object to be more than it really is. Thus, he determined, by meaſuring the actual height of ſome of the heavenly bodies, when to his eye they ſeemed to be half way between the horizon and the zenith; that their real altitude was then only 23°: when the ſun was about 30° high, the upper always appeared leſs than the under; and he thought that it was conſtantly greater when the ſun was 18° or 20° high. Mr. Robins, in his

his Tracts, vol. 2, pa. 245, ſhews how to determine the apparent concavity of the ſky in a more accurate and geometrical manner; by which it appears, that if the altitude of any of the heavenly bodies be 20°, at the time when it ſeems to be half way between the horizon and the zenith, the horizontal diſtance will be hardly leſs than 4 times the perpendicular diſtance; but if that altitude be 28°, it will be little more than 2 and a half.

Dr. Smith, having determined the apparent figure of the ſky, thus applies it to explain the phenomenon of the horizontal moon, and other ſimilar appearances in the heavens. Suppoſe the arc ABC to re-



preſent that apparent concavity; then the diameter of the ſun and moon would ſeem to be greater in the horizon than at any altitude, meaſured by the angle AOB, in the ratio of its apparent diſtances, AO, BO. The numbers that expreſs theſe proportions he reduced into the annexed table, anſwering to the correſponding altitudes of the ſun or moon, which are alſo exactly repreſented to the eye in the figure, in which the moon, placed in the quadrantal arc FG deſcribed about the centre O, are all equal to each other, and repreſent the body of the moon in the heights there noted, and the unequal moons in the concavity ABC are terminated by the viſual rays coming from the circumference of the real moon, at thoſe heights to the eye, at O. Dr. Smith alſo obſerves, that the apparent concave of the ſky, being leſs than a hemiſphere, is the cauſe that the breadths of the colours in the inward and outward rainbows, and the interval between the bows, appear leaſt at the top, and greater at the bottom. This

theory of the horizontal moon is alſo confirmed by the appearances of the tails of comets, which, whatever be their real figure, magnitude, and ſituation in abſolute ſpace, do always appear to be an arc of the concave ſky. Dr. Smith however juſtly acknowledges that, at different times, the moon appears of very different magnitudes, even in the ſame horizon, and occaſionally of an extraordinary large ſize; which he is not able to give a ſatisfactory explanation of. Smith's Optics, vol. 1, pa. 63, &c, Remarks, pa. 53.

MAIGNAN (Emanuel), a religious minim, and one of the greateſt philoſophers of his age, was born at Thouloufe in 1601. Like the famous Paſcal, he became a complete mathematician without the aſſiſtance of a teacher; and filled the profeſſor's chair at Rome in 1636, where, at the expence of Cardinal Spada, he publiſhed his book *De Perſpectiva Horaria*, in 1648. Upon this book, Baillet, in his Life of Des Cartes, has the following paſſage: "M. Carcavi acquainted Des Cartes, that there was at Rome one father Maignan, a minim, of greater learning and more depth than father Merſenne, who made him expect ſome objections againſt his principles. This father's proper name was Emanuel, and his native place Thouloufe: but he lived at that time at Rome, where he taught divinity in the convent of the Trinity upon Mount Pincio, which they otherwiſe call the convent of the French minims." Maignan returned to Thouloufe in 1650, and was created Provincial. His knowledge in mathematics, and phyſical experiments, were very early known; eſpecially from a diſpute which aroſe between him and father Kircher, about the invention of a catoptrical work.

The king, who in 1660 amuſed himſelf with the machines and curioſities in the father's cell, made him offers by Cardinal Mazarin, to draw him to Paris; but he humbly deſired to ſpend the remainder of his days in a cloyſter.—He publiſhed a Courſe of Philoſophy, in 4 volumes 8vo, at Thouloufe, in 1652; to the ſecond edition of which, in folio, 1673, he added two Treatiſes; the one againſt the vortices of Des Cartes, the other upon the ſpeaking trumpet invented by Sir Samuel Morland.—He formed a machine, which ſhewed, by its movements, that Des Cartes's ſuppoſition concerning the manner in which the univerſe was formed, or might have been formed, and concerning the centrifugal force, was entirely without foundation.

Thus this great philoſopher and divine paſſed a life of tranquillity, in writing books, making experiments, and reading lectures. He was frequently conſulted by the moſt eminent philoſophers; and has had a thouſand anſwers to make, either by writing or otherwiſe. Never was mortal leſs inclined to idleneſs. It is ſaid that he even ſtudied in his ſleep; for his very dreams employed him in problems, which he purſued ſometimes till he came to a ſolution or demonſtration; and he has frequently been awaked out of his ſleep of a ſudden, by the exquiſite pleaſure which he felt upon diſcovery of it. The excellence of his manners, and his unſpotted virtues, rendered him no leſs worthy of eſteem, than his genius and learning.—It is ſaid that he compoſed with great eaſe, and without any alterations at all.—He died at Thouloufe in 1676, at 75 years of age.

MALLEABLE, the property of a ſolid ductile body, from which it may be beaten, forged, and ex-

tended under the hammer, without breaking, which is a property of all metals.

MANFREDI (EUSTACHIO), a celebrated aſtronomer and mathematician, born at Bologna in 1674. His genius was always above his age. He was a tolerable poet, and wrote ingenious verſes while he was but a child. And while very young he formed in his father's houſe an academy of youth of his own age, who became the Academy of Sciences, or the Inſtitute, there. He became Profeſſor of Mathematics at Bologna in 1698, and Superintendant of the waters there in 1704. The ſame year he was placed at the head of the College of Montalte, founded at Bologna for young men intended for the church. In 1711 he obtained the office of Aſtronomer to the Inſtitute of Bologna. He became member of the Academy of Sciences of Paris in 1726, and of the Royal Society of London in 1729; and died the 15th of February 1739.—His works are:

1, *Ephemerides Motuum Cœleſtium ab anno* 1715 *ad annum* 1750; 4 volumes in 4to.—The firſt volume is an excellent introduction to aſtronomy; and the other three contain numerous calculations. His two ſiſters were greatly aſſiſting to him in compoſing this work.

2. *De Tranſitu Mercurii per Solem, anno* 1723. Bologna 1724, in 4to.

3. *De Annuis Inerrantium Stellarum Aberrationibus*, Bologna 1729, in 4to.—Beſides a number of papers in the Memoirs of the Academy of Sciences, and in other places.

MANILIUS (MARCUS), a Latin aſtronomical poet, who lived in the reign of Auguſtus Cæſar. He wrote an ingenious poem concerning the ſtars and the ſphere, called *Aſtronomicon;* which, not being mentioned by any of the ancient poets, was unknown, till about two centuries ſince, when it was found buried in ſome German library, and publiſhed by Poggius. There is no account to be found of this author, but what can be drawn from his poem; which contains a ſyſtem of the ancient aſtronomy and aſtrology, together with the philoſophy of the Stoics. It conſiſts of five books; though there was a ſixth, which has not been recovered. In this work, Manilius hints at ſome opinions, which later ages have been ready to glory in as their own diſcoveries. Thus, he defends the fluidity of the heavens, againſt the hypotheſis of Ariſtotle: he aſſerts that the fixed ſtars are not at all in the ſame concave ſuperficies of the heavens, and equally diſtant from the centre of the world: he maintains that they are all of the ſame nature and ſubſtance with the ſun, and that each of them has a particular vortex of its own: and laſtly, he ſays, that the milky way is only the united luſtre of a great many ſmall imperceptible ſtars; which indeed the Moderns now ſee to be ſuch through their teleſcopes.

The beſt editions of Manilius are, that of Joſeph Scaliger, in 4to, 1600; that of Bentley, in 4to, 1738, and that of Edmund Burton, Eſq. in 8vo, 1783.

MANOMETER, or MANOSCOPE, an inſtrument to ſhew or meaſure the alterations in the rarity or denſity of the air.

The Manometer differs from the barometer in this, That the latter only ſerves to meaſure the *weight* of the atmoſphere, or of the column of air over it; but the former, the denſity of the air in which it is found; which denſity depends not only on the weight of the atmoſphere, but alſo on the action of heat and cold, &c. Authors however often confound the two together; and Mr. Boyle himſelf has given a very good Manometer of his contrivance, under the name of a Statical Barometer, conſiſting of a bubble of thin glaſs, about the ſize of an orange, which being counterpoiſed when the air was in a mean ſtate of denſity, by means of a nice pair of ſcales, ſunk when the atmoſphere became lighter, and roſe as it grew heavier.

The Manometer uſed by captain Phipps, in his voyage towards the North Pole, conſiſted of a tube of a ſmall bore, with a ball at the end. The barometer being at 29·7, a ſmall quantity of quickſilver was put into the tube, to take off the communication between the external air, and that confined in the ball and the part of the tube below this quickſilver. A ſcale is placed on the ſide of the tube, which marks the degrees of dilatation ariſing from the increaſe of heat in this ſtate of the weight of the air, and has the ſame graduation as that of Fahrenheit's thermometer, the point of freezing being marked 32. In this ſtate therefore it will ſhew the degrees of heat in the ſame manner as a thermometer. But when the air becomes lighter, the bubble incloſed in the ball, being leſs compreſſed, will dilate itſelf, and occupy a ſpace as much larger as the compreſſing force is leſs; therefore the changes ariſing from the increaſe of heat, will be proportionably larger; and the inſtrument will ſhew the differences in the denſity of the air, ariſing from the changes in its weight and heat. Mr. Ramſden found, that a heat equal to that of boiling water, increaſed the magnitude of the air, from what it was at the freezing point, by $\frac{414}{1000}$ of the whole. Hence it follows, that the ball and the part of the tube below the beginning of the ſcale, is of a magnitude equal to almoſt 414 degrees of the ſcale. If the height of both the Manometer and thermometer be given, the height of the barometer may be thence deduced, by this rule;

as the height of the Manometer increaſed by 414,
to the height of the thermometer increaſed by 414,
ſo is 29·7, to the height of the barometer;

or if m denote the height of the Manometer, and t the height of the thermometer; then

$$m + 414 : t + 414 :: 29{\cdot}7 : \frac{t + 414}{m + 414} \times 29{\cdot}7,$$

which is the height of the barometer.

Another kind of Manometer was made uſe of by colonel Roy, in his attempts to correct the errors of the barometer; which is deſcribed in the Philoſ. Tranſ. vol. 67, pa. 689.

MANTELETS, a kind of moveable parapet, or ſcreen, of about 6 feet high, ſet upon trucks or little wheels, and guided by a long pole; ſo that in a ſiege it may be driven before the pioneers, and ſerve as blinds, or ſcreens, to ſhelter them from the enemy's ſmall ſhot. Mantelets are made of different materials, ſo as to render them muſket proof; as of ſtrong boards nailed together, and covered with tin; or of thick leather, or of layers of rope, &c, firmly bound together.

There are alſo other ſorts of Mantelets, covered on the top, uſed by the miners in approaching the walls or works of an enemy. The double Mantelets form an angle,

angle, and ſtand ſquare, making two fronts. It appears from Vegetius, that Mantelets were in uſe among the Ancients, under the name of Vineæ.

MANTLE, or MANTLE-*tree*, is the lower part of the breaſt or front of a chimney. It was formerly a piece of timber that lay acroſs the jambs, ſupporting the breaſtwork; but by a late act of parliament, chimney-breaſts are not to be ſupported by a wooden mantle-tree, or turning piece, but by an iron bar, or by an arch of brick or ſtone.

MAP, a plane figure repreſenting the ſurface of the earth, or ſome part of it; being a projection of the globular ſurface of the earth, exhibiting countries, ſeas, rivers, mountains, cities, &c, in their due poſitions, or nearly ſo.

Maps are either Univerſal or Particular, that is Partial.

Univerſal MAPS are ſuch as exhibit the whole ſurface of the earth, or the two hemiſpheres.

Particular, or *Partial* MAPS, are thoſe that exhibit ſome particular region, or part of the earth.

Both kinds are uſually called Geographical, or Land-Maps, as diſtinguiſhed from Hydrographical, or Sea-Maps, which repreſent only the ſeas and ſea coaſts, and are properly called *Charts*.

Anaximander, the ſcholar of Thales, it is ſaid, about 400 years before Chriſt, firſt invented geographical tables, or Maps. The Pentingerian Tables, publiſhed by Cornelius Pentinger of Auſburgh, contain an itinerary of the whole Roman Empire; all places, except ſeas, woods, and deſarts, being laid down according to their meaſured diſtances, but without any mention of latitude, longitude, or bearing.

The Maps publiſhed by Ptolomy of Alexandria, about the 144th year of Chriſt, have meridians and parallels, the better to define and determine the ſituation of places, and are great improvements on the conſtruction of Maps. Though Ptolomy himſelf owns that his Maps were copied from ſome that were made by Marinus, Tirus, &c, with the addition of ſome improvements of his own. But from his time till about the 14th century, during which, geography and moſt ſciences were neglected, no new Maps were publiſhed. Mercator was the firſt of note among the Moderns, and next to him Ortelius, who undertook to make a new ſet of Maps, with the modern diviſions of countries and names of places; for want of which, thoſe of Ptolomy were become almoſt uſeleſs. After Mercator, many others publiſhed Maps, but for the moſt part they were mere copies of his. Towards the middle of the 17th century, Bleau in Holland, and Sanſon in France, publiſhed new ſets of Maps, with many improvements from the travellers of thoſe times, which were afterwards copied, with little variation, by the Engliſh, French, and Dutch; the beſt of theſe being thoſe of Viſcher and De Witt. And later obſervations have furniſhed us with ſtill more accurate and copious ſets of Maps, by De Liſle, Robert, Wells, &c, &c. Concerning Maps, ſee Varenius's Geog. lib. 3, cap. 3, prop. 4; Fournier's Hydrog. lib. 4, c. 24; Wolfius's Elem. Hydrog. c. 9; John Newton's Idea of Navigation; Mead's Conſtruction of Globes and Maps; Wright's Conſtructions of Maps, &c, &c.

Conſtruction of MAPS. Maps are conſtructed by making a projection of the globe, either on the plane of ſome particular circle, or by the eye placed in ſome particular point, according to the rules of Perſpective, &c; of which there are ſeveral methods.

Firſt, to conſtruct a Map of the World, or a general Map.

1ſt *Method.*—A map of the world muſt repreſent two hemiſpheres; and they muſt both be drawn upon the plane of that circle which divides the two hemiſpheres. The firſt way is to project each hemiſphere upon the plane of ſome particular circle, by the rules of Orthographic projection, forming two hemiſpheres, upon one common baſe or circle. When the plane of projection is that of a meridian, the maps will be the eaſt and weſt hemiſpheres, the other meridians will be ellipſes, and the parallel circles will be right lines. Upon the plane of the equinoctial, the meridians will be right lines croſſing in the centre, which will repreſent the pole, and the parallels of latitude will be circles having that common centre, and the Maps will be the northern and ſouthern hemiſpheres. The fault of this way of drawing Maps, is, that near the outſide the circles are too near one another; and therefore equal ſpaces on the earth are repreſented by very unequal ſpaces upon the Map.

2d *Method.*—Another way is to project the ſame hemiſpheres by the rules of Stereographic projection; in which way, all the parallels will be repreſented by circles, and the meridians by circles or right lines. And here the contrary fault happens, viz, the circles towards the outſides are too far aſunder, and about the middle they are too near together.

3d *Method.*—To remedy the faults of the two former methods, proceed as follows. Firſt, for the eaſt and weſt hemiſpheres, deſcribe the circle PENQ for the meridian (pl. xvii, fig. 1), or plane of projection; through the centre of which draw the equinoctial EQ, and axis PN perpendicular to it, making P and N the north and ſouth pole. Divide the quadrants PE, EN, NQ, and QP into 9 equal parts, each repreſenting 10 degrees, beginning at the equinoctial EQ: divide alſo CP and CN into 9 equal parts; beginning at EQ; and through the correſponding points draw the parallels of latitude. Again, divide CE and CQ into 9 equal parts; and through the points of diviſion, and the two poles P and N, draw circles, or rather ellipſes, for the meridians. So ſhall the Map be prepared to receive the ſeveral places and countries of the earth.

Secondly, for the north or ſouth hemiſphere, draw AQBE, for the equinoctial (fig. 2), dividing it into the four quadrants EA, AQ, QB, and BE; and each quadrant into 9 equal parts, repreſenting each 10 degrees of longitude; and then, from the points of diviſion, draw lines to the centre C, for the circles of longitude. Divide any circle of longitude, as the firſt meridian EC, into 9 equal parts, and through theſe points deſcribe circles from the centre C, for the parallels of latitude; numbering them as in the figure.

In this 3d method, equal ſpaces on the earth are repreſented by equal ſpaces on the Map, as near as any projection will bear; for a ſpherical ſurface can no way be repreſented exactly upon a plane. Then the ſeveral countries of the world, ſeas, iſlands, ſea-coaſts, towns, &c,

&c, are to be entered in the Map, according to their latitudes and longitudes.

In filling up the Map, all places repreſenting land are filled with ſuch things as the countries contain; but the ſeas are left white; the ſhores adjoining to the ſea being ſhaded. Rivers are marked by ſtrong lines, or by double lines, drawn winding in form of the rivers they repreſent; and ſmall rivers are expreſſed by ſmall lines. Different countries are beſt diſtinguiſhed by different colours, or at leaſt the borders of them. Foreſts are repreſented by trees; and mountains ſhaded to make them appear. Sands are denoted by ſmall points or ſpecks; and rocks under water by a ſmall croſs. In any void ſpace, draw the mariner's compaſs, with the 32 points or winds.

II. *To draw a Map of any particular Country.*

1ſt *Method.*—For this purpoſe its extent muſt be known, as to latitude and longitude; as ſuppoſe Spain, lying between the north latitudes 36 and 44, and extending from 10 to 23 degrees of longitude; ſo that its extent from north to ſouth is 8 degrees, and from eaſt to weſt 13 degrees.

Draw the line AB for a meridian paſſing through the middle of the country (fig. 3), on which ſet off 8 degrees from B to A, taken from any convenient ſcale; A being the north, and B the ſouth point. Through A and B draw the perpendiculars CD, EF, for the extreme parallels of latitude. Divide AB into 8 parts, or degrees, through which draw the other parallels of latitude, parallel to the former.

For the meridians; divide any degree in AB into 60 equal parts, or geographical miles. Then, becauſe the length of a degree in each parallel decreaſes towards the pole, from the table ſhewing this decreaſe, under the article DEGREE, take the number of miles anſwering to the latitude of B, which is 48½ nearly, and ſet it from B, 7 times to E, and 6 times to F; ſo is EF divided into degrees. Again, from the ſame table take the number of miles of a degree in the latitude A, viz 43⅝ nearly; which ſet off, from A, 7 times to C, and 6 times to D. Then from the points of diviſion in the line CD, to the correſponding points in the line EF, draw ſo many right lines, for the meridians. Number the degrees of latitude up both ſides of the Map, and the degrees of longitude on the top and bottom. Alſo, in ſome vacant place make a ſcale of miles; or of degrees, if the Map repreſent a large part of the earth; to ſerve for finding the diſtances of places upon the Map.

Then make the proper diviſions and ſubdiviſions of the country: and having the latitudes and longitudes of the principal places, it will be eaſy to ſet them down in the Map: for any town, &c, muſt be placed where the circles of its latitude and longitude interſect. For inſtance, Gibraltar, whoſe latitude is 36° 11′, and longitude 12° 27′, will be at G: and Madrid, whoſe lat. is 40° 10′, and long. 14° 44′, will be at M. In like manner the mouth of a river muſt be ſet down; but to deſcribe the whole river, the latitude and longitude of every turning muſt be marked down, and the towns and bridges by which it paſſes. And ſo for woods, foreſts, mountains, lakes, caſtles, &c. The boundaries will be deſcribed, by ſetting down the remarkable places on the ſea-coaſt, and drawing a continued line through them all. And this way is very proper for ſmall countries.

2d *Method.*—Maps of particular places are but portions of the globe, and therefore may be drawn after the ſame manner as the whole is drawn. That is, ſuch a Map may be drawn either by the orthographic or ſtereographic projection of the ſphere, as in the laſt prob. But in partial Maps, an eaſier way is as follows. Having drawn the meridian AB (fig. 3), and divided it into equal parts as in the laſt method, through all the points of diviſion draw lines perpendicular to AB, for the parallels of latitude; CD, EF being the extreme parallel. Then to divide theſe, ſet off the degrees in each parallel, diminiſhed after the manner directed for the two extreme parallels CD, EF, in the laſt method: and through all the correſponding points draw the meridians, which will be curve lines; which were right lines in the laſt method; becauſe only the extreme parallels were divided by the table. This method is proper for a large tract, as Europe, &c; in which caſe the parallels and meridians need only be drawn to every 5 or 10 degrees. This method is much uſed in drawing Maps; as all the parts are nearly of their due magnitude, but a little diſtorted towards the outſide, from the oblique interſections of the meridians and parallels.

3d *Method.*—Draw PB of a convenient length, for a meridian; divide it into 9 equal parts, and through the points of diviſion, deſcribe as many circles for the parallels of latitude, from the centre P, which repreſents the pole. Suppoſe AB (fig. 4) the height of the Map; then CD will be the parallel paſſing through the greateſt latitude, and EF will repreſent the equator. Divide the equator EF into equal parts, of the ſame ſize as thoſe in AB, both ways, beginning at B. Divide alſo all the parallels into the ſame number of equal parts, but leſſer, in proportion to the numbers for the ſeveral latitudes, as directed in the laſt method for the rectilineal parallels. Then through all the correſponding diviſions, draw curve lines, which will repreſent the meridians, the extreme ones being EC and FD. Laſtly, number the degrees of latitude and longitude, and place a ſcale of equal parts, either of miles or degrees, for meaſuring diſtances.—This is a very good way of drawing large Maps, and is called the globular projection; all the parts of the earth being repreſented nearly of their due magnitude, excepting that they are a little diſtorted on the outſides.

When the place is but ſmall that a Map is to be made of, as if a county was to be exhibited; the meridians, as to ſenſe, will be parallel to one another, and the whole will differ very little from a plane. Such a Map will be made more eaſily than by the preceding rules. It will here be ſufficient to meaſure the diſtances of places in miles, and ſo lay them down in a plane rectangular map. But this belongs more properly to Surveying.

The Uſe of MAPS is obvious from their conſtruction. The degrees of the meridians and parallels ſhew the latitudes and longitudes of places; and the ſcale of miles annexed, their diſtances; the ſituation of places, with regard to each other, as well as to the cardinal points, appears by inſpection; the top of the map being always the north, the bottom the ſouth, the right hand the

eaſt,

eaſt, and the left hand the weſt; unleſs the compaſs, uſually annexed, ſhew the contrary.

MARALDI (James Philip), a learned aſtronomer and mathematician, was born in 1665 at Perinaldo in the county of Nice, a place already honoured by the birth of his maternal uncle the celebrated Caſſini. Having made a conſiderable progreſs in mathematics, at the age of 22 his uncle, who had been a long time ſettled in France, invited him there, that he might himſelf cultivate the promiſing genius of his nephew. Maraldi no ſooner applied himſelf to the contemplation of the heavens, than he conceived the deſign of forming a catalogue of the fixed ſtars, the foundation of all the aſtronomical edifice. In conſequence of this deſign, he applied himſelf to obſerve them with the moſt conſtant attention; and he became by this means ſo intimate with them, that on being ſhewn any one of them, however ſmall, he could immediately tell what conſtellation it belonged to, and its place in that conſtellation. He has been known to diſcover thoſe ſmall comets, which aſtronomers often take for the ſtars of the conſtellation in which they are ſeen, for want of knowing preciſely what ſtars the conſtellation conſiſts of, when others, on the ſpot, and with eyes directed equally to the ſame part of the heavens, could not for a long time ſee any thing of them.

In 1700 he was employed under Caſſini in prolonging the French meridian to the northern extremity of France, and had no ſmall ſhare in completing it. He then ſet out for Italy, where Clement the 11th invited him to aſſiſt at the aſſemblies of the Congregation then ſitting in Rome to reform the calendar. Bianchini alſo availed himſelf of his aſſiſtance to conſtruct the great meridian of the Carthuſian church in that city. In 1718 Maraldi, with three other academicians, prolonged the French meridian to the ſouthern extremity of that country. He was admitted a member of the Academy of Sciences of Paris in 1699, in the department of Aſtronomy, and communicated a great multitude of papers, which are printed in their memoirs, in almoſt every year from 1699 to 1729, and uſually ſeveral papers in each of the years; for he was indefatigable in his obſervations of every thing that was curious and uſeful in the motions and phenomena of the heavenly bodies. As to the catalogue of the fixed ſtars, it was not quite completed: juſt as he had placed a mural quadrant on the terras of the obſervatory, to obſerve ſome ſtars towards the north and the zenith, he fell ſick, and died the 1ſt of December 1729.

MARCH, the 3d month of the year, according to the common way of computing, and conſiſts of 31 days. The ſun enters the ſign Aries about the 20th or 21ſt day of this month.

Among the Romans, March was the firſt month; and in ſome eccleſiaſtical computations, that order is ſtill preſerved. In England, before the alteration of the ſtile, March was the 1ſt month in order, the year always commencing with the 25th day of the month.

It has been ſaid it was Romulus who firſt divided the year into months; to the firſt of which he gave the name of his ſuppoſed father Mars. It is obſerved by Ovid, however, that the people of Italy had the month of March before the time of Romulus; but that they placed it differently; ſome making it the third, ſome the 4th, ſome the 5th, and others the 10th month of the year.

MARINERS-Compass. See Compass.

MARIOTTE (Edme), an eminent French philoſopher and mathematician, was born at Dijon, and admitted a member of the Academy of Sciences of Paris in 1666. His works however are better known than his life. He was a good mathematician, and the firſt French philoſopher who applied much to experimental phyſics. The law of the ſhock or colliſion of bodies, the theory of the preſſure and motion of fluids, the nature of viſion, and of the air, particularly engaged his attention. He carried into his philoſophical reſearches, that ſpirit of ſcrutiny and inveſtigation ſo neceſſary to thoſe who would make any conſiderable progreſs in it. He died in 1684.

He communicated a number of curious and valuable papers to the Academy of Sciences, which were printed in the collection of their Memoirs dated 1666, viz, from volume 1 to volume 10. And all his works were collected into 2 volumes in 4to, and printed at Leyden in 1717.

MARS, one of the ſeven primary planets now known, and the firſt of the four ſuperior ones, being placed immediately next above the earth. It is uſually denoted by this character ♂, being a mark rudely formed from a man holding a ſpear protruded, repreſenting the god of war of the ſame name.

The mean diſtance of Mars from the ſun, is 1524 of thoſe parts, of which the diſtance of the earth from the ſun is 1000; his excentricity 141; and his real diſtance 145 millions of miles. The inclination of his orbit to the plane of the ecliptic, is 1° 52′; the length of his year, or the period of one revolution about the ſun, is 686$\frac{3}{4}$ of our days, or 667$\frac{3}{4}$ of his own days, which are 40 minutes longer than ours, the revolution on his axis being performed in 24 hours 40 minutes. His mean diameter is 4444 miles; and the ſame ſeen from the ſun is 11″: the inclination of the axis to his orbit 0° 0′; the inclination of his orbit to the ecliptic 1° 52′; place of the aphelion ♍ 0° 32′; place of his aſcending node ♉ 17° 17′; and his parallax, according to Dr. Hook and Mr. Flamſteed, is ſcarce 30 ſeconds.

Dr. Hook, in 1665, obſerved ſeveral ſpots in Mars; which having a motion, he concluded the planet turned round its centre. In 1666, M. Caſſini obſerved ſeveral ſpots in the two faces or hemiſpheres of Mars, which he found made one revolution in 24hours 40minutes. Theſe obſervations were repeated in 1670, and confirmed by Miraldi in 1704, and 1719: whence both the motion and period, or natural day, of that planet, were determined.

In the Philoſ. Tranſ. for 1781, Mr. Herſchel gave a ſeries of obſervations on the rotation of this planet about its axis, from which he concluded that one mean ſidereal rotation was between 24 h. 39 m. 5 ſec. and 24 h. 39 m. 22 ſec.; and in the Philoſ. Tranſ. for 1784, is given a paper by the ſame gentleman, on the remarkable appearances at the polar regions of the planet Mars, the inclination of its axis, the poſition of its poles, and its ſphereoidical figure; with a few hints relating to its real diameter and atmoſphere, deduced from his

his obſervations taken from the year 1777 to 1783 incluſively. He obſerved ſeveral remarkable bright ſpots near both poles, which had ſome ſmall motion; and the reſults of his obſervations are as follow; viz,

"Inclination of axis to the ecliptic, 59° 22′.
The node of the axis is in ♈ 17° 47′.
Obliquity of the planet's ecliptic 28° 42′.
The point Aries on Mars's ecliptic anſwers to our ♐ 19° 28′.

The figure of Mars is that of an oblate ſpheroid, whoſe equatorial diameter is to the polar one, as 1355 to 1272, or as 16 to 15 nearly.

The equatorial diameter of Mars, reduced to the mean diſtance of the earth from the ſun, is 9″ 8‴.

And the planet has a conſiderable, but moderate atmoſphere, ſo that its inhabitants probably enjoy a ſituation in many reſpects ſimilar to ours."

Mars always appears with a ruddy troubled light; owing, it is ſuppoſed, to the nature of his atmoſphere, through which the light paſſes.

In the acronical riſing of this planet, or when in oppoſition to the ſun, it is five times nearer to us than when in conjunction with him; and ſo appears much larger and brighter than at other times.

Mars, having his light from the ſun, and revolving round it, has an increaſe and decreaſe like the moon: it may alſo be obſerved almoſt biſected, when in the quadratures, or in perigæon; but is never ſeen cornicular, as the inferior planets. All which ſhews both that his orbit includes that of the earth within it, and that he ſhines not by his own light.

MARTIN (Benjamin), was born in 1704, and became one of the moſt celebrated mathematicians and opticians of his time. He firſt taught a ſchool in the country; but afterwards came up to London, where he read lectures on experimental philoſophy for many years, and carried on a very extenſive trade as an optician and globe-maker in Fleet-ſtreet, till the growing infirmities of old age compelled him to withdraw from the active part of buſineſs. Truſting too fatally to what he thought the integrity of others, he unfortunately, though with a capital more than ſufficient to pay all his debts, became a bankrupt. The unhappy old man, in a moment of deſperation from this unexpected ſtroke, attempted to deſtroy himſelf; and the wound, though not immediately mortal, haſtened his death, which happened the 9th of February 1782, at 78 years of age.

He had a valuable collection of foſſils and curioſities of almoſt every ſpecies; which after his death were almoſt given away by public auction. He was indefatigable as an artiſt, and as a writer he had a very happy method of explaining his ſubject, and wrote with clearneſs, and even conſiderable elegance. He was chiefly eminent in the ſcience of optics; but he was well ſkilled in the whole circle of the mathematical and philoſophical ſciences, and wrote uſeful books on every one of them; though he was not diſtinguiſhed by any remarkable inventions or diſcoveries of his own. His publications were very numerous, and generally uſeful: ſome of the principal of them were as follow:

The Philoſophical Grammar; being a View of the preſent State of Experimental Phyſiology, or Natural Philoſophy, 1735, 8vo.—A new, complete, and univerſal Syſtem or Body of Decimal Arithmetic, 1735, 8vo.—The Young Student's Memorial Book, or Pocket Library, 1735, 8vo.—Deſcription and Uſe of both the Globes, the Armillary Sphere and Orrery, Trigonometry, 1736, 2 vols. 8vo.—Syſtem of the Newtonian Philoſophy, 1759, 3 vols.—New Elements of Optics, 1759.—Mathematical Inſtitutions, 1764, 2 vols.—Philologic and Philoſophical Geography, 1759.—Lives of Philoſophers, their inventions, &c. 1764.—Young Gentleman and Lady's Philoſophy, 1764, 3 vols.—Miſcellaneous Correſpondence, 1764, 4 vols.—Inſtitutions of Aſtronomical Calculations, 3 parts, 1765.—Introduction to the Newtonian Philoſophy, 1765.—Treatiſe of Logarithms.—Treatiſe on Navigation.—Deſcription and Uſe of the Air-pump.—Deſcription of the Torricellian Barometer.—Appendix to the Uſe of the Globes.—Philoſophia Britannica, 3 vols.—Principles of Pump-work.—Theory of the Hydrometer.—Deſcription and Uſe of a Caſe of Mathematical Inſtruments.—Ditto of a Univerſal Sliding Rule.—Micrographia, on the Microſcope.—Principles of Perſpective.—Courſe of Lectures.—Optical Eſſays.—Eſſay on Electricity.—Eſſay on Viſual Glaſſes or Spectacles.—Horologia Nova, or New Art of Dialling.—Theory of Comets.—Nature and Conſtruction of Solar Eclipſes.—Venus in the Sun.—The Mariner's Mirror.—Thermometrum Magnum.—Survey of the Solar Syſtem.—Eſſay on Iſland Chryſtal.—Logarithmologia Nova, &c. &c.

MASCULINE *Signs*. Aſtrologers divide the Signs, &c, into Maſculine and Feminine; by reaſon of their qualities, which are either active, and hot, or cold, accounted Maſculine; or paſſive, dry, and moiſt, which are feminine. On this principle they call the Sun, Jupiter, Saturn, and Mars, Maſculine; and the Moon and Venus, feminine. Mercury, they ſuppoſe, partakes of the two. Among the Signs, they account Aries, Libra, Gemini, Leo, Sagittarius, and Aquarius, Maſculine; but Cancer, Capricornus, Taurus, Virgo, Scorpio, and Piſces are feminine.

MASS, the quantity of matter in any body. This is rightly eſtimated by its weight; whatever be its figure, or whether its bulk or magnitude be large or ſmall.

MATERIAL, relating to Matter.

MATHEMATICAL, relating to Mathematics.

Mathematical *Sect*, is one of the two leading philoſophical ſects, which aroſe about the beginning of the 17th century; the other being the Metaphyſical ſect. The former directed its reſearches by the principles of Gaſſendi, and ſought after truth by obſervation and experience. The diſciples of this ſect denied the poſſibility of erecting on the baſis of metaphyſical and abſtract truths, a regular and ſolid ſyſtem of philoſophy, without the aid of aſſiduous obſervation and repeated experiments, which are the moſt natural and effectual means of philoſophical progreſs and improvement. The advancement and reputation of this ſect, and of natural knowledge in general, were much owing to the plan of philoſophizing propoſed by lord Bacon, to the eſtabliſhment of the Royal Society in London,

London, to the genius and induſtry of Mr. Boyle, and to the unparalleled reſearches and diſcoveries of Sir Iſaac Newton. Barrow, Wallis, Locke, and many other great luminaries in learning, adorned this ſect.

MATHEMATICS, the ſcience of quantity; or a ſcience that conſiders magnitudes either as computable or meaſurable.

The word in its original, μαθησις, *mathefis*, ſignifies *diſcipline* or *ſcience* in general; and, it ſeems, has been applied to the doctrine of quantity, either by way of eminence, or becauſe, this having the ſtart of all other ſciences, the reſt took their common name from it.

As to the origin of the Mathematics, Joſephus dates it before the flood, and makes the ſons of Seth obſervers of the courſe and order of the heavenly bodies: he adds, that to perpetuate their diſcoveries, and ſecure them from the injuries either of a deluge or a conflagration, they had them engraven on two pillars, the one of ſtone, the other of brick; the former of which, he ſays, was yet ſtanding in Syria in his time.

Indeed it is pretty generally agreed that the firſt cultivators of Mathematics, after the flood, were the Aſſyrians and Chaldeans; from whom, Joſephus adds, the ſcience was carried by Abraham to the Egyptians; who proved ſuch notable proficients, that Ariſtotle even fixes the firſt riſe of Mathematics among them. From Egypt, 584 years before Chriſt, Mathematics paſſed into Greece, being carried thither by Thales; who having learned geometry of the Egyptian prieſts, taught it in his own country. After Thales, came Pythagoras; who, among other Mathematical arts, paid a particular regard to arithmetic; drawing the greateſt part of his philoſophy from numbers. He was the firſt, according to Laertius, who abſtracted geometry from matter; and to him we owe the doctrine of incommenſurable magnitude, and the five regular bodies, beſides the firſt principles of muſic and aſtronomy. To Pythagoras ſucceeded Anaxagoras, Oenopides, Briſo, Antipho, and Hippocrates of Scio; all of whom particularly applied themſelves to the quadrature of the circle, the duplicature of the cube, &c; but the laſt with moſt ſucceſs of any: he is alſo mentioned by Proclus, as the firſt who compiled elements of Mathematics.

Democritus excelled in Mathematics as well as phyſics; though none of his works in either kind are extant; the deſtruction of which is by ſome authors aſcribed to Ariſtotle. The next in order is Plato, who not only improved geometry, but introduced it into phyſics, and ſo laid the foundation of a ſolid philoſophy. From his ſchool aroſe a crowd of mathematicians. Proclus mentions 13 of note; among whom was Leodamus, who improved the analyſis firſt invented by Plato; Theætetus, who wrote Elements; and Archytas, who has the credit of being the firſt that applied Mathematics to uſe in life. Theſe were ſucceeded by Neocles and Theon, the laſt of whom contributed to the elements. Eudoxus excelled in arithmetic and geometry, and was the firſt founder of a ſyſtem of aſtronomy. Menechmus invented the conic ſections, and Theudius and Hermotimus improved the elements.

For Ariſtotle, his works are ſo ſtored with Mathematics, that Blancanus compiled a whole book of them: out of his ſchool came Eudemus and Theophraſtus; the firſt of whom wrote upon numbers, geometry, and inviſible lines; and the latter compoſed a mathematical hiſtory. To Ariſteus, Iſidorus, and Hypſicles, we owe the books of Solids; which, with the other books of Elements, were improved, collected, and methodiſed by Euclid, who died 284 years before the birth of Chriſt.

A hundred years after Euclid, came Eratoſthenes and Archimedes: and contemporary with the latter was Conon, a geometrician and aſtronomer. Soon after came Apollonius Pergæus; whoſe excellent conics are ſtill extant. To him are alſo aſcribed the 14th and 15th books of Euclid, and which, it is ſaid, were contracted by Hypſicles. Hipparchus and Menelaus wrote on the ſubtenſes of the arcs in a circle; and the latter alſo on ſpherical triangles. Theodoſius's 3 books of Spherics are ſtill extant. And all theſe, Menelaus excepted, lived before Chriſt.

Seventy years after Chriſt, was born Ptolomy of Alexandria; a good geometrician, and the prince of aſtronomers: to him ſucceeded the philoſopher Plutarch, ſome of whoſe Mathematical problems are ſtill extant. After him came Eutocius, who commented on Archimedes, and occaſionally mentions the inventions of Philo, Diocles, Nicomedes, Sporus, and Heron, on the duplicature of the cube. To Cteſebes of Alexandria we are indebted for pumps; and Geminus, who lived ſoon after, is preferred by Proclus to Euclid himſelf.

Diophantus of Alexandria was a great maſter of numbers, and the firſt Greek writer on Algebra. Among others of the Ancients, Nicomachus is celebrated for his arithmetical, geometrical, and muſical works: Serenus, for his books on the ſection of the cylinder; Proclus, for his commentaries on Euclid; and Theon has the credit among ſome, of being author of the books of elements aſcribed to Euclid. The laſt to be named among the Ancients, is Pappus of Alexandria, who flouriſhed about the year of Chriſt 400, and is juſtly celebrated for his books of Mathematical collections, ſtill extant.

Mathematics are commonly diſtinguiſhed into *Speculative* and *Practical*, *Pure* and *Mixed*.

Speculative MATHEMATICS, is that which barely contemplates the properties of things: and

Practical MATHEMATICS, that which applies the knowledge of thoſe properties to ſome uſes in life.

Pure MATHEMATICS is that branch which conſiders quantity abſtractedly, and without any relation to matter or bodies.

Mixed MATHEMATICS conſiders quantity as ſubſiſting in material being; for inſtance, length in a pole, depth in a river, height in a tower, &c.

Pure Mathematics, again, either conſiders quantity as diſcrete, and ſo computable, as arithmetic; or as concrete, and ſo meaſureable, as geometry.

Mixed Mathematics are very extenſive, and are diſtinguiſhed by various names, according to the different ſubjects it conſiders, and the different views in which it is taken; ſuch as Aſtronomy, Geography, Optics, Hydroſtatics, Navigation, &c, &c.

Pure Mathematics has one peculiar advantage, that it occaſions no conteſts among wrangling diſputants, as happens in other branches of knowledge: and the

reaſon is, becauſe the definitions of the terms are premiſed, and every perſon that reads a propoſition has the ſame idea of every part of it. Hence it is eaſy to put an end to all mathematical controverſies, by ſhewing, either that our adverſary has not ſtuck to his definitions, or has not laid down true premiſes, or elſe that he has drawn falſe concluſions from true principles; and in caſe we are not able to do either of theſe, we muſt acknowledge the truth of what he has proved.

It is true, that in mixed Mathematics, where we reaſon mathematically upon phyſical ſubjects, ſuch juſt definitions cannot be given as in geometry; we muſt therefore be content with deſcriptions; which will be of the ſame uſe as definitions, provided we be conſiſtent with ourſelves, and always mean the ſame thing by thoſe terms we have once explained.

Dr. Barrow gives a very elegant deſcription of the excellence and uſefulneſs of mathematical knowledge, in his inaugural oration, upon being appointed Profeſſor of Mathematics at Cambridge. The Mathematics, he obſerves, effectually exerciſe, not vainly delude, nor vexatiouſly torment ſtudious minds with obſcure ſubtilties, but plainly demonſtrate every thing within their reach, draw certain concluſions, inſtruct by profitable rules, and unfold pleaſant queſtions. Theſe diſciplines likewiſe enure and corroborate the mind to a conſtant diligence in ſtudy; they wholly deliver us from a credulous ſimplicity, moſt ſtrongly fortify us againſt the vanity of ſcepticiſm, effectually reſtrain us from a raſh preſumption, moſt eaſily incline us to a due aſſent, and perfectly ſubject us to the government of right reaſon. While the mind is abſtracted and elevated from ſenſible matter, diſtinctly views pure forms, conceives the beauty of ideas, and inveſtigates the harmony of proportions; the manners themſelves are ſenſibly corrected and improved, the affections compoſed and rectified, the fancy calmed and ſettled, and the underſtanding raiſed and excited to more divine contemplations.

MATTER, an extended ſubſtance. Other properties of Matter are, that it reſiſts, is ſolid, diviſible, moveable, paſſive, &c; and it forms the principles of which all bodies are compoſed.

Matter and form, the two ſimple and original principles of all things, according to the Ancients, compoſing ſome ſimple natures, which they called Elements; from the various combinations of which all natural things were afterwards compoſed.

Dr. Woodward was of opinion, that Matter is originally and really various, being at firſt creation divided into ſeveral ranks, ſets, or kinds of corpuſcles, differing in ſubſtance, gravity, hardneſs, flexibility, figure, ſize, &c; from the various compoſitions and combinations of which, he thinks, ariſe all the varieties in bodies as to colour, hardneſs, gravity, taſtes, &c. But it is Sir Iſaac Newton's opinion, that all thoſe differences reſult from the various arrangements of the ſame Matter; which he accounts homogeneous and uniform in all bodies.

The quantity of Matter in any body, is its meaſure ariſing from the joint conſideration of the magnitude and denſity of the body; as if one body be twice as denſe as another, and alſo occupy twice the ſpace, then will it contain 4 times the Matter of the other. This quantity of Matter is beſt diſcovered by the weight or gravity of the body, to which it is always proportional.

Newton obſerves, that "it ſeems probable, God, in the beginning, formed Matter in ſolid, maſſy, hard, impenetrable, moveable particles, of ſuch ſizes, figures, and with ſuch other properties, and in ſuch proportion to ſpace, as moſt conduced to the end for which he formed them; and that theſe primitive particles, being ſolid, are incomparably harder than any porous bodies compounded of them; even ſo very hard, as never to wear, and break in pieces: no ordinary power being able to divide what God himſelf made one in the firſt creation. While the particles continue entire, they may compoſe bodies of one and the ſame nature and texture in all ages; but ſhould they wear away, or break in pieces, the nature of things depending on them would be changed. Water and earth, compoſed of old worn particles, would not be of the ſame nature and texture now with water and earth compoſed of entire particles in the beginning. And therefore, that nature may be laſting, the changes of corporeal things are to be placed only in the various ſeparations and new aſſociations and motions of theſe permanent particles; compound bodies being apt to break, not in the midſt of ſolid particles, but where thoſe particles are laid together, and touch in a few points. It ſeems farther, he continues, that theſe particles have not only a vis inertiæ, accompanied with ſuch paſſive laws of motion as naturally reſult from that force, but alſo that they are moved by certain active principles, ſuch as is that of gravity, and that which cauſeth fermentation, and the coheſion of bodies. Theſe principles are to be conſidered not as occult qualities, ſuppoſed to reſult from the ſpecific forms of things, but as general laws of nature, by which the things themſelves are formed; their truth appearing to us by phenomena, though their cauſes are not yet diſcovered."

Hobbes, Spinoza, &c, maintain that all the beings in the univerſe are material, and that their differences ariſe from their different modifications, motions, &c. Thus they conceive that Matter extremely ſubtile, and in a briſk motion, may think; and ſo they exclude ſpirit out of the world.

Dr. Berkley, on the contrary, argues againſt the exiſtence of Matter itſelf; and endeavours to prove that it is a mere *ens rationis*, and has no exiſtence out of the mind.

Some late philoſophers have advanced a new hypotheſis concerning the nature and eſſential properties of Matter. The firſt of theſe who ſuggeſted, or at leaſt publiſhed an account of this hypotheſis, was M. Boſcovich, in his Theoria Philoſophiæ Naturalis. He ſuppoſes that Matter is not impenetrable, but that it conſiſts of phyſical points only, endued with powers of attraction and repulſion, taking place at different diſtances, that is, ſurrounded with various ſpheres of attraction and repulſion; in the ſame manner as ſolid Matter is generally ſuppoſed to be. Provided therefore that any body move with a ſufficient degree of velocity, or have ſufficient momentum to overcome any power of repulſion that it may meet with, it will find no difficulty in making its way through any body whatever. If the velocity of ſuch a body in motion be ſufficiently great, Boſcovich contends, that the particles of any body through which it paſſes, will not even be moved,

moved out of their place by it. With a degree of velocity ſomething leſs than this, they will be conſiderably agitated, and ignition might perhaps be the conſequence, though the progreſs of the body in motion would not be ſenſibly interrupted; and with a ſtill leſs momentum it might not paſs at all.

Mr. Michell, Dr. Prieſtley, and ſome others of our own country, are of the ſame opinion. See Prieſtley's Hiſtory of Diſcoveries relating to Light, pa. 390.—In conformity to this hypotheſis, this author maintains, that Matter is not that inert ſubſtance that it has been ſuppoſed to be; that powers of attraction or repulſion are neceſſary to its very being, and that no part of it appears to be impenetrable to other parts. Accordingly, he defines Matter to be a ſubſtance, poſſeſſed of the property of extenſion, and of powers of attraction or repulſion, which are not diſtinct from Matter, and foreign to it, as it has been generally imagined, but abſolutely eſſential to its very nature and being: ſo that when bodies are diveſted of theſe powers, they become nothing at all. In another place, Dr. Prieſtley has given a ſomewhat different account of Matter; according to which it is only a number of centres of attraction and repulſion; or more properly of centres, not diviſible, to which divine agency is directed; and as ſenſation and thought are not incompatible with theſe powers, ſolidity, or impenetrability, and conſequently a vis inertiæ only having been thought repugnant to them, he maintains, that we have no reaſon to ſuppoſe that there are in man two ſubſtances abſolutely diſtinct from each other. See Diſquiſitions on Matter and Spirit.

But Dr. Price, in a correſpondence with Dr. Prieſtley, publiſhed under the title of A Free Diſcuſſion of the Doctrines of Materialiſm and Philoſophical Neceſſity, 1778, has ſuggeſted a variety of unanſwerable objections againſt this hypotheſis of the penetrability of Matter, and againſt the concluſions that are drawn from it. The vis inertiæ of Matter, he ſays, is the foundation of all that is demonſtrated by natural philoſophers concerning the laws of the colliſion of bodies. This, in particular, is the foundation of Newton's philoſophy, and eſpecially of his three laws of motion. Solid Matter has the power of acting on other Matter by impulſe; but unſolid Matter cannot act at all by impulſe; and this is the only way in which it is capable of acting, by any action that is properly its own. If it be ſaid, that one particle of Matter can act upon another without contact and impulſe, or that Matter can, by its own proper agency, attract or repel other Matter which is at a diſtance from it, then a maxim hitherto univerſally received muſt be falſe, that "nothing can act where it is not." Newton, in his letters to Bentley, calls the notion, that Matter poſſeſſes an innate power of attraction, or that it can act upon Matter at a diſtance, and attract and repel by its own agency, an abſurdity into which he thought no one could poſſibly fall. And in another place he expreſſly diſclaims the notion of innate gravity, and has taken pains to ſhew that he did not take it to be an eſſential property of bodies. By the ſame kind of reaſoning purſued, it muſt appear, that Matter has not the power of attracting and repelling; that this power is the power of ſome foreign cauſe, acting upon Matter according to ſtated laws; and conſequently that attraction and repulſion, not being actions, much leſs inherent qualities of Matter, as ſuch, it ought not to be defined by them. And if Matter has no other property, as Dr. Prieſtley aſſerts, than the power of attracting and repelling, it muſt be a non-entity; becauſe this is a property that cannot belong to it. Beſides, all power is the power of ſomething; and yet if Matter is nothing but this power, it muſt be the power of nothing; and the very idea of it is a contradiction. If Matter be not ſolid extenſion, what can it be more than mere extenſion?

Farther, Matter that is not ſolid, is the ſame with pore; and therefore it cannot poſſeſs what philoſophers mean by the momentum or force of bodies, which is always in proportion to the quantity of Matter in bodies, void of pore.

MAUNDY THURSDAY, is the Thurſday in Paſſion week; which was called *Maundy* or *Mandate Thurſday*, from the command which Chriſt gave his apoſtles to commemorate him in the Lord's Supper, which he this day inſtituted; or from the new commandment which he gave them to love one another, after he had waſhed their feet as a token of his love to them.

MAUPERTUIS (PETER LOUIS MORCEAU DE), a celebrated French mathematician and philoſopher, was born at St Malo in 1698, and was there privately educated till he attained his 16th year, when he was placed under the celebrated profeſſor of philoſophy, M. le Blond, in the college of la Marche, at Paris; while M. Guiſnée, of the Academy of Sciences, was his inſtructor in mathematics. For this ſcience he ſoon diſcovered a ſtrong inclination, and particularly for geometry. He likewiſe practiſed inſtrumental muſic in his early years with great ſucceſs; but fixed on no profeſſion till he was 20, when he entered into the army; in which he remained about 5 years, during which time he purſued his mathematical ſtudies with great vigour; and it was ſoon remarked by M. Freret and other academicians, that nothing but mathematics could ſatisfy his active ſoul and unbounded thirſt for knowledge.

In the year 1723, he was received into the Royal Academy of Sciences, and read his firſt performance, which was a memoir upon the conſtruction and form of muſical inſtruments. During the firſt years of his admiſſion, he did not wholly confine his attention to mathematics; he dipt into natural philoſophy, and diſcovered great knowledge and dexterity in obſervations and experiments upon animals.

If the cuſtom of travelling into remote countries, like the ſages of antiquity, in order to be initiated into the learned myſteries of thoſe times, had ſtill ſubſiſted, no one would have conformed to it with more eagerneſs than Maupertuis. His firſt gratification of this paſſion was to viſit the country which had given birth to Newton; and during his reſidence at London he became as zealous an admirer and follower of that philoſopher as any one of his own countrymen. His next excurſion was to Baſil in Switzerland, where he formed a friendſhip with the celebrated John Bernoulli and his family, which continued till his death. At his return to Paris, he applied himſelf to his favourite ſtudies with greater zeal than ever. And how well he ful-

filled the duties of an academician, may be ſeen by running over the Memoirs of the Academy from the year 1724 to 1744; where it appears that he was neither idle, nor occupied by objects of ſmall importance. The moſt ſublime queſtions in the mathematical ſciences, received from his hand that elegance, clearneſs, and preciſion, ſo remarkable in all his writings.

In the year 1736, he was ſent to the polar circle, to meaſure a degree of the meridian, in order to aſcertain the figure of the earth; in which expedition he was accompanied by Meſſ. Clairault, Camus, Monnier, Outhier, and Celſus the celebrated profeſſor of aſtronomy at Upſal. This buſineſs rendered him ſo famous, that on his return he was admitted a member of almoſt every academy in Europe.

In the year 1740, Maupertuis had an invitation from the king of Pruſſia to go to Berlin; which was too flattering to be refuſed. His rank among men of letters had not wholly effaced his love for his firſt profeſſion, that of arms. He followed the king to the field, but at the battle of Molwitz was deprived of the pleaſure of being preſent, when victory declared in favour of his royal patron, by a ſingular kind of adventure. His horſe, during the heat of the action, running away with him, he fell into the hands of the enemy; and was at firſt but roughly treated by the Auſtrian Huſſars, to whom he could not make himſelf known for want of language; but being carried priſoner to Vienna, he received ſuch honours from the emperor as never were effaced from his memory. Maupertuis lamented very much the loſs of a watch of Mr. Graham's, the celebrated Engliſh artiſt, which they had taken from him; the emperor, who happened to have another by the ſame artiſt, but enriched with diamonds, preſented it to him, ſaying, "the Huſſars meant only to jeſt with you, they have ſent me your watch, and I return it to you."

He went ſoon after to Berlin; but as the reform of the academy which the king of Pruſſia then meditated was not yet mature, he repaired to Paris, where his affairs called him, and was choſen in 1742 director of the Academy of Sciences. In 1743 he was received into the French Academy; which was the firſt inſtance of the ſame perſon being a member of both the academies at Paris at the ſame time. Maupertuis again aſſumed the ſoldier at the ſiege of Fribourg, and was pitched upon by marſhal Coigny and the count d'Argenſon to carry the news to the French king of the ſurrender of that citadel.

Maupertuis returned to Berlin in the year 1744, when a marriage was negotiated and brought about, by the good offices of the queen mother, between our author and madamoiſelle de Borck, a lady of great beauty and merit, and nearly related to M. de Borck at that time miniſter of ſtate. This determined him to ſettle at Berlin, as he was extremely attached to his new ſpouſe, and regarded this alliance as the moſt fortunate circumſtance of his life.

In the year 1746, Maupertuis was declared, by the king of Pruſſia, Preſident of the Royal Academy of Sciences at Berlin, and ſoon after by the ſame prince was honoured with the Order of Merit. However, all theſe accumulated honours and advantages, ſo far from leſſening his ardour for the ſciences, ſeemed to furniſh new allurements to labour and application. Not a day paſſed but he produced ſome new project or eſſay for the advancement of knowledge. Nor did he confine himſelf to mathematical ſtudies only: metaphyſics, chemiſtry, botany, polite literature, all ſhared his attention, and contributed to his fame. At the ſame time he had, it ſeems, a ſtrange inquietude of ſpirit, with a dark atrabilaire humour, which rendered him miſerable amidſt honours and pleaſures. Such a temperament did not promiſe a pacific life; and he was in fact engaged in ſeveral quarrels. One of theſe was with Koenig the profeſſor of philoſophy at Franeker, and another more terrible with Voltaire. Maupertuis had inſerted in the volume of Memoirs of the Academy of Berlin for 1746, a diſcourſe upon the laws of motion; which Koenig was not content with attacking, but attributed to Leibnitz. Maupertuis, ſtung with the imputation of plagiariſm, engaged the academy of Berlin to call upon him for his proof; which Koenig failing to produce, his name was ſtruck out of the academy, of which he was a member. Several pamphlets were the conſequence of this meaſure; and Voltaire, for ſome reaſon or other, engaged in the quarrel againſt Maupertuis. We ſay, for ſome reaſon or other; becauſe Maupertuis and Voltaire were apparently upon the moſt amicable terms; and the latter reſpected the former as his maſter in the mathematics. Voltaire upon this occaſion exerted all his wit and ſatire againſt him; and upon the whole was ſo much tranſported beyond what was thought right, that he found it expedient in 1753 to quit the court of Pruſſia.

Our philoſopher's conſtitution had long been conſiderably impaired by the great fatigues of various kinds in which his active mind had involved him; though from the amazing hardſhips he had undergone, in his northern expedition, moſt of his bodily ſufferings may be traced. The intenſe ſharpneſs of the air could only be ſupported by means of ſtrong liquors; which helped but to lacerate his lungs, and bring on a ſpitting of blood, which began at leaſt 12 years before he died. Yet ſtill his mind ſeemed to enjoy the greateſt vigour; for the beſt of his writings were produced, and moſt ſublime ideas developed, during the time of his confinement by ſickneſs, when he was unable to occupy his preſidial chair at the academy. He took ſeveral journeys to St. Malo, during the laſt years of his life, for the recovery of his health: and though he always received benefit by breathing his native air, yet ſtill, upon his return to Berlin, his diſorder likewiſe returned with greater violence. His laſt journey into France was undertaken in the year 1757; when he was obliged, ſoon after his arrival there, to quit his favourite retreat at St. Malo, on account of the danger and confuſion which that town was thrown into by the arrival of the Engliſh in its neighbourhood. From thence he went to Bourdeaux, hoping there to meet with a neutral ſhip to carry him to Hamburgh, in his way back to Berlin; but being diſappointed in that hope, he went to Toulouſe, where he remained ſeven months. He had then thoughts of going to Italy, in hopes a milder climate would reſtore him to health; but finding himſelf grow worſe, he rather inclined towards Germany, and went to Neufchatel, where for three

months

months he enjoyed the converſation of lord Mariſchal, with whom he had formerly been much connected. At length he arrived at Baſil, October 16, 1758, where he was received by his friend Bernoulli and his family with the utmoſt tenderneſs and affection. He at firſt found himſelf much better here than he had been at Neufchatel: but this amendment was of ſhort duration; for as the winter approached, his diſorder returned, accompanied by new and more alarming ſymptoms. He languiſhed here many months, during which he was attended by M. de la Condamine; and died in 1759, at 61 years of age.

The works which he publiſhed were collected into 4 volumes 8vo, publiſhed at Lyons in 1756, where alſo a new and elegant edition was printed in 1768. Theſe contain the following works:

1. Eſſay on Coſmology.—2. Diſcourſe on the different Figures of the Stars.—3. Eſſay on Moral Philoſophy.—4. Philoſophical Reflections upon the Origin of Languages, and the Signification of Words.—5. Animal Phyſics, concerning Generation &c.—6. Syſtem of Nature, or the Formation of bodies.—7. Letters on various ſubjects.—8. On the Progreſs of the Sciences.—9. Elements of Geography.—10. Account of the Expedition to the Polar Circle, for determining the Figure of the Earth; or the Meaſure of the Earth at the Polar Circle.—11. Account of a Journey into the Heart of Lapland, to ſearch for an Ancient Monument.—12. On the Comet of 1742.—13. Various Academical Diſcourſes, pronounced in the French and Pruſſian Academies.—14. Diſſertation upon Languages.—15. Agreement of the Different Laws of Nature, which have hitherto appeared incompatible.—16. Upon the Laws of Motion.—17. Upon the Laws of Reſt.—18. Nautical Aſtronomy.—19. On the Parallax of the Moon.—20. Operations for determining the Figure of the Earth, and the Variations of Gravity.—21. Meaſure of a Degree of the Meridian at the Polar Circle.

Beſide theſe works, Maupertuis was author of a great multitude of intereſting papers, particularly thoſe printed in the Memoirs of the Paris and Berlin Academies, far too numerous here to mention; viz, in the Memoirs of the Academy at Paris, from the year 1724, to 1749; and in thoſe of the Academy of Berlin, from the year 1746, to 1756.

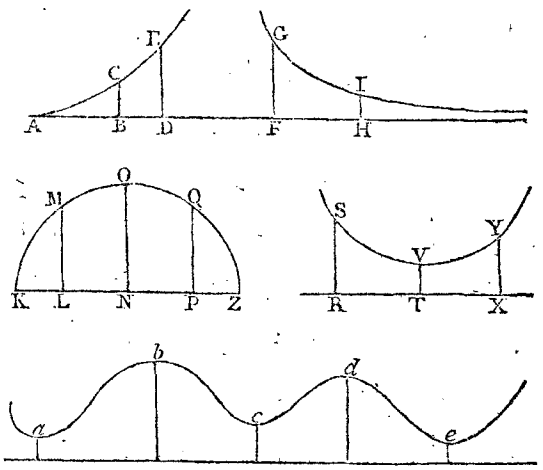
MAXIMUM, denotes the greateſt ſtate or quantity attainable in any given caſe, or the greateſt value of a variable quantity. By which it ſtands oppoſed to Minimum, which is the leaſt poſſible quantity in any caſe.

As in the algebraical expreſſion $a^2 - bx$, where a and b are conſtant or invariable quantities, and x a variable one. Now it is evident that the value of this remainder or difference, $a^2 - bx$, will increaſe as the term bx, or x, decreaſes; and therefore that will be the greateſt when this is the ſmalleſt; that is, $a^2 - bx$ is a maximum, when x is the leaſt, or nothing at all.

Again, the expreſſion or difference $a^2 - \frac{b}{x}$, evidently increaſes as the fraction $\frac{b}{x}$ diminiſhes; and this diminiſhes as x increaſes; therefore the given expreſſion will be the greateſt, or a maximum, when x is the greateſt, or infinite.

Alſo, if along the diameter KZ *(the 3d fig. below)* of a circle, a perpendicular ordinate LM be conceived to move, from K towards Z; it is evident that, from K it increaſes continually till it arrive at the centre, in the poſition NO, where it is at the greateſt ſtate; and from thence it continually decreaſes again, as it moves along from N to Z, and quite vaniſhes at the point Z. So that the maximum ſtate of the ordinate is NO, equal to the radius of the circle.

Methodus de MAXIMIS *et* MINIMIS, a method of finding the greateſt or leaſt ſtate or value of a variable quantity.



Some quantities continually increaſe, and ſo have no maximum but what is infinite; as the ordinates BC, DE of the parabola ACE: Some continually decreaſe, and ſo their leaſt or minimum ſtate is nothing; as the ordinates FG, HI, to the aſymptotes of the hyperbola. Others increaſe to a certain magnitude, which is their maximum, and then decreaſe again; as the ordinates LM &c of the circle. And others again decreaſe to a certain magnitude TV, which is their minimum, and then increaſe again; as the ordinates of the curve SVY. While others admit of ſeveral maxima and minima; as the ordinates of the curve *abcde*, where at *b* and *d* they are maxima, and *a*, *c*, *e*, minima. And thus the maxima and minima of all other variable quantities may be conceived; expreſſing thoſe quantities by the ordinates of ſome curves.

The firſt maxima and minima are found in the Elements of Euclid, or flow immediately from them: thus, it appears, by the 5th prop. of book 2, that the greateſt rectangle that can be made of the two parts of a given line, any how divided, is when the line is divided equally in the middle; prob. 7, book 3, ſhews that the greateſt line that can be drawn from a given point within a circle, is that which paſſes through the centre; and that the leaſt line that can be ſo drawn, is the continuation of the ſame to the other ſide of the circle: prop. 8 ib. ſhews the ſame for lines drawn from a point without the circle: and thus other inſtances might be pointed out in the Elements.—Other writers on the Maxima and Minima, are, Apollonius, in the whole 5th book of his Conic Sections; and

and in the Preface or Dedication to that book, he ſays others had then alſo treated the ſubject, though in a ſlighter manner.—Archimedes; as in prop. 9 of his Treatiſe on the Sphere and Cylinder, where he demonſtrates that, of all ſpherical ſegments under equal ſuperficies, the hemiſphere is the greateſt.—Serenus, in his 2d book, or that on the Conic Sections.—Pappus, in many parts of his Mathematical Collections; as in lib. 3, prop. 28 &c, lib. 6, prop. 31 &c, where he treats of ſome curious caſes of variable geometrical quantities, ſhewing how ſome increaſe and decreaſe both ways to infinity; while others proceed only one way, by increaſe or decreaſe, to infinity, and the other way to a certain magnitude; and others again both ways to a certain magnitude, giving a maximum and minimum; alſo lib. 7, prop. 13, 14, 165, 166, &c. And all theſe are the geometrical Maxima and Minima of the Ancients; to which may be added ſome others of the ſame kind, viz. Viviani De Maximis & Minimis Geometrica Divinatio in quintum Conicorum Apollonii Pergæi, in fol. at Flor. 1659; alſo an ingenious little tract in Thomas Simpſon's Geometry, on the Maxima and Minima of Geometrical Quantities.

Other writings on the Maxima and Minima are chiefly treated in a more general way by the modern analyſis; and firſt among theſe perhaps may be placed that of Fermat. This, and other methods, are beſt referred to, and explained by the ordinates of curves. For when the ordinate of a curve increaſes to a certain magnitude, where it is greateſt, and afterwards decreaſes again, it is evident that two ordinates on the contrary ſides of the greateſt ordinate may be equal to each other; and the ordinates decreaſe to a certain point, where they are at the leaſt, and afterwards increaſe again; there may alſo be two equal ordinates, one on each ſide of the leaſt ordinate. Hence then an equal ordinate corresponds to two different abſciſſes, or for every value of an ordinate there are two values of abſciſſes. Now as the difference between the two abſciſſes is conceived to become leſs and leſs, it is evident that the two equal ordinates, corresponding to them, approach nearer and nearer together; and when the differences of the abſciſſes are infinitely little, or nothing, then the equal ordinates unite in one, which is either the maximum or minimum. The method hence derived then, is this: Find two values of an ordinate, expreſſed in terms of the abſciſſes: put thoſe two values equal to each other, cancelling the parts that are common to both, and dividing all the remaining terms by the difference between the abſciſſes, which will be a common factor in them: next, ſuppoſing the abſciſſes to become equal, that the equal ordinates may concur in the maximum or minimum, that difference will vaniſh, as well as all the terms of the equation that include it; and therefore, ſtriking thoſe terms out of the equation, the remaining terms will give the value of the abſciſs corresponding to the maximum or minimum.

For example, ſuppoſe it were required to find the greateſt ordinate in a circle KMQ. Put the diameter KZ $= a$, the abſciſs KL $= x$, the ordinate LM $= y$; hence the other part of the diameter is LZ $= a - x$, and conſequently, by the nature of the circle KL $\times$ LZ being equal LM^2, $x \times \overline{a - x}$ or $ax - x^2 = y^2$. Again, put another abſciſs KP $= x + d$, where d is the difference LP, the ordinate PQ, being equal to LM or y; here then again KP $\times$ PZ $=$ PQ^2, or $\overline{x + d} \times \overline{a - x - d} = ax - x^2 - 2dx + ad - d^2 = y^2$; put now theſe two values of y^2 equal to each other, ſo ſhall $ax - x^2 = ax - x^2 - 2dx + ad - d^2$; cancel the common terms ax and x^2, then $0 = -2dx + ad - d^2$, or $2dx + d^2 = ad$; divide all by d, ſo ſhall $2x + d = a$, a general equation derived from the equality of the two ordinates. Now, bringing the two equal ordinates together, or making the two abſciſſes equal, their difference d vaniſhes, and the laſt equation becomes barely $2x = a$, or $x = \frac{1}{2}a$, $=$ KN, the value of the abſciſs KN when the ordinate NO is a maximum, viz, the greateſt ordinate biſects the diameter. And the operation and concluſion it is evident will be the ſame, to divide a given line into two parts, ſo that their rectangle ſhall be the greateſt poſſible.

For a ſecond example, let it be required to divide the given line AB into two ſuch parts, that the one line drawn into the ſquare of the other may be the greateſt poſſible. Putting the given line AB $= a$, and one part AC $= x$; then the other part CB will be $a - x$, and therefore $x^2 \times \overline{a - x} = ax^2 - x^3$ is the product of one part by the ſquare of the other. Again, let one part be AD $= x + d$, then the other part is $a - x - d$, and $\overline{x + d}^2 \times \overline{a - x - d} = ax^2 - x^3 - 3dx^2 + \overline{2ad - 3d^2} \cdot x + ad^2 - d^3$. Then, putting theſe two products equal to each other, cancelling the common terms $ax^2 - x^3$, and dividing the remainder by d, there reſults $0 = -3x^2 + \overline{2a - 3d} \cdot x + ad - d^2$; hence, cancelling all the terms that contain d, there remains $0 = -3x^2 + 2ax$, or $3x = 2a$, and, $x = \frac{2}{3}a$; that is, the given line muſt be divided into two parts in the ratio of 3 to 2. See Fermat's Opera Varia, pa. 63, and his Letters to F. Merſenne.

A B C D

The next method was that of John Hudde, given by Schooten among the additions to Des Cartes's Geometry, near the end of the 1ſt vol. of his edition. This method is alſo drawn from the property of an equation that has two equal roots. He there demonſtrates that, having ranged the terms of an equation, that has two roots equal, according to the order of the exponents of the unknown quantity, taking all the terms over to one ſide, and ſo making them equal to nothing on the other ſide; if then the terms in that order be multiplied by the terms of any arithmetical progreſſion, the reſulting equation will ſtill have one of its roots equal to one of the two equal roots of the former equation. Now ſince, by what has been ſaid of the foregoing method, when the ordinate of a curve, admitting of a maximum or minimum, is expreſſed in terms of the abſciſſa, that abſciſſa, or the value of x, will be two-fold, becauſe there are two ordinates of the ſame value; that is, the equation has at leaſt two unequal roots or values of x: but when the ordinate becomes a maximum or minimum, the two abſciſſes unite in one, and the two roots, or values of x, are equal; therefore, from the above ſaid property, the terms of this equation for the maximum or minimum being multiplied by the terms of any arithmetical progreſſion, the root of the reſulting equation

tion will be one of the ſaid equal roots, or the value of the abſciſs x when the ordinate is a maximum.

Although the terms of any arithmetic progreſſion may be uſed for this purpoſe, ſome are more convenient than others; and Mr. Hudde directs to make uſe of that progreſſion which is formed by the exponents of x, viz, to multiply each term by the exponent of its power, and putting all the reſulting products equal to nothing; which, it is evident, is exactly the ſame proceſs as taking the fluxions of all the terms, and putting them equal to nothing; being the common proceſs now uſed for the ſame purpoſe.

Thus, in the former of the two foregoing examples, where $ax - x^2$, or y^2, is to be a maximum;
mult. by 1 2
gives $ax - 2x^2 = 0$; hence $2x = a$, and $x = \frac{1}{2}a$, as before.

And in the 2d example, where $ax^2 - x^3$, is to be a maximum; mult. by - - 2 3
gives - - - - $2ax^2 - 3x^3 = 0$; hence $2a - 3x = 0$, or $3x = 2a$, and $x = \frac{2}{3}a$, as before.

The next general method, and which is now uſually practiſed, is that of Newton, or the method of Fluxions, which proceeds upon a principle different from that of the two former methods of Fermat and Hudde. Theſe proceed upon the idea of the two equal ordinates of a curve uniting into one, at the place of the maximum and minimum; but Newton's upon the principle, that the fluxion or increment of an ordinate is nothing, at the point of the maximum or minimum; a circumſtance which immediately follows from the nature of that doctrine: for, ſince a quantity ceaſes to increaſe at the maximum, and to decreaſe at the minimum, at thoſe points it neither increaſes nor decreaſes; and ſince the fluxion of a quantity is proportional to its increaſe or decreaſe, therefore the fluxion is nothing at the maximum or minimum. Hence this rule: Take the fluxion of the algebraical expreſſion denoting the maximum or minimum, and put it equal to nothing; and that equation will determine the value of the unknown letter or quantity in queſtion.

So in the firſt of the two foregoing examples, where it is required to determine x when $ax - x^2$ is a maximum: the fluxion of this is $a\dot{x} - 2x\dot{x} = 0$; divide by $\dot{x}$, ſo ſhall $a - 2x = 0$, or $a = 2x$, and $x = \frac{1}{2}a$.

Alſo, in the 2d example, where $ax^2 - x^3$ muſt be a maximum: here the fluxion is $2ax\dot{x} - 3x^2\dot{x} = 0$; hence $2a - 3x = 0$, or $2a = 3x$, and $x = \frac{2}{3}a$.

When a quantity becomes a maximum or minimum, and is expreſſed by two or more affirmative and negative terms, in which only one variable letter is contained; it is evident that the fluxion of the affirmative terms will be equal to the fluxion of the negative ones; ſince their difference is equal to nothing.

And when, in the expreſſion for the fluxion of a maximum or minimum, there are two or more fluxionary letters, each contained in both affirmative and negative terms; the ſum of the terms containing the fluxion of each letter, will be equal to nothing: For, in order that any expreſſion be a maximum or minimum, which contains two or more variable quantities, it muſt produce a maximum or minimum, if but one of thoſe quantities be ſuppoſed variable. So if $ax - 2xy + by$ denote a minimum; its fluxion is $a\dot{x} - 2y\dot{x} - 2x\dot{y} + b\dot{y}$; hence $a\dot{x} - 2y\dot{x} = 0$, and $b\dot{y} - 2x\dot{y} = 0$; from the former of theſe $y = \frac{1}{2}a$, and from the latter $x = \frac{1}{2}b$. Or, in ſuch a caſe, take the fluxion of the whole expreſſion, ſuppoſing only one quantity variable; then take the fluxion again, ſuppoſing another quantity only variable: and ſo on, for all the ſeveral variable quantities; which will give the ſame number of equations for determining thoſe quantities. So, in the above example, $ax - 2xy + by$, the fluxion is $a\dot{x} - 2y\dot{x} = 0$, ſuppoſing only x variable; which gives $y = \frac{1}{2}a$: and the fluxion is $-2x\dot{y} + b\dot{y} = 0$, when y only is variable; which gives $x = \frac{1}{2}b$; the ſame as before.

Farther, when any quantity is a maximum or minimum, all the powers or roots of it will be ſo too; as will alſo the reſult be, when it is increaſed or decreaſed, or multiplied, or divided by a given or conſtant quantity; and the logarithm of the ſame will be alſo a maximum or minimum.

To find whether a propoſed algebraic quantity admits of a maximum or minimum.—Every algebraic expreſſion does not admit of a maximum or minimum, properly ſo called; for it may either increaſe continually to infinity, or decreaſe continually to nothing; in both which caſes there is neither a proper maximum nor minimum; for the true maximum is that value to which an expreſſion increaſes, and after which it decreaſes again; and the minimum is that value to which the expreſſion decreaſes, and after that it increaſes again. Therefore when the expreſſion admits of a maximum, its fluxion is poſitive before that point, and negative after it; but when it admits of a minimum, its fluxion is negative before, and poſitive after it. Hence, take the fluxion of the expreſſion a little before the fluxion is equal to nothing, and a little after it; if the firſt fluxion be poſitive, and the laſt negative, the middle ſtate is a maximum; but if the firſt fluxion be negative, and the laſt poſitive, the middle ſtate is a minimum. See Maclaurin's Fluxions, book 1, chap. 9, and book 2, chap. 5, art. 859.

MAY, *Maius*, the fifth month in the year, reckoning from our firſt or January; but the third, counting the year to begin with March, as the Romans did anciently. It was called Maius by Romulus, in reſpect to the ſenators and nobles of his city, who were named *majores*; as the following month was called *Junius*, in honour of the youth of Rome, *in honorem juniorum*, who ſerved him in the war. Though ſome ſay it has been thus called from *Maia*, the mother of Mercury, to whom they offered ſacrifice on the firſt day of this month: and Papias derives the name from *Madius, eo quod tunc terra madeat*.

In this month the ſun enters the ſign Gemini, and the plants of our hemiſphere begin moſtly to flower.

MAYER (Tobias), one of the greateſt aſtronomers and mechaniſts of the 18th century, was born at Maſpach, in the duchy of Wirtemberg, 1723. He taught himſelf mathematics, and at 14 years of age deſigned machines and inſtruments with the greateſt dexterity and juſtneſs. Theſe purſuits did not hinder him from cultivating the Belles Lettres. He acquired the Latin tongue, and wrote it with elegance. In 1750, the univerſity of Gottingen choſe him for their mathematical profeſſor; and every year of his ſhort life

was thenceforward marked with ſome conſiderable diſcoveries in geometry and aſtronomy. He publiſhed ſeveral works in this way, which are all accounted excellent of their kind; and ſome papers are inſerted in the ſecond volume of the Memoirs of the Univerſity of Gottingen. He was very accurate and indefatigable in his aſtronomical obſervations; indeed his labours ſeem to have very early exhauſted him; for he died worn out in 1762, at no more than 39 years of age.

His Table of Refractions, deduced from his aſtronomical obſervations, very nicely agrees with that of Doctor Bradley; and his Theory of the Moon, and Aſtronomical Tables and Precepts, were ſo well eſteemed, that they were rewarded by the Engliſh Board of Longitude, with the premium of three thouſand pounds, which ſum was paid to his widow after his death. Theſe tables and precepts were publiſhed by the Board of Longitude in 1770.

MEAN, a middle ſtate between two extremes: as a mean motion, mean diſtance, arithmetical mean, geometrical mean, &c.

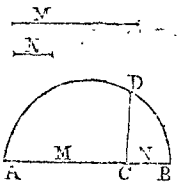
Arithmetical MEAN, is half the ſum of the extremes. So, 4 is an arithmetical mean between 2 and 6, or between 3 and 5, or between 1 and 7; alſo an arithmetical mean between a and b is $\frac{a+b}{2}$ or $\frac{1}{2}a + \frac{1}{2}b$.

Geometrical MEAN, commonly called a mean proportional, is the ſquare root of the product of the two extremes; ſo that, to find a mean proportional between two given extremes, multiply theſe together, and extract the ſquare root of the product. Thus, a mean proportional between 1 and 9, is $\sqrt{1 \times 9} = \sqrt{9} = 3$; a mean between 2 and $4\frac{1}{2}$ is $\sqrt{2 \times 4\frac{1}{2}} = \sqrt{9} = 3$ alſo; the mean between 4 and 6 is $\sqrt{4 \times 6} = \sqrt{24}$; and the mean between a and b is $\sqrt{ab}$.

The geometrical mean is always leſs than the arithmetical mean, between the ſame two extremes. So the arithmetical mean between 2 and $4\frac{1}{2}$ is $3\frac{1}{4}$, but the geometrical mean is only 3. To prove this generally; let a and b be any two terms, a the greater, and b the leſs; then, univerſally, the arithmetical mean $\frac{a+b}{2}$ ſhall be greater than the geometrical mean $\sqrt{ab}$, or $a + b$ greater than $2\sqrt{ab}$. For, by

ſquaring both, they are	$a^2 + 2ab + b^2$	$> 4ab$;
ſubtr. $4ab$ from each, then	$a^2 - 2ab + b^2$	> 0,
that is - - -	$(a - b)^2$	> 0.

To find a Mean Proportional Geometrically, between two given lines M and N. Join the two given lines together at C in one continued line AB; upon the diameter AB deſcribe a ſemicircle, and erect the perpendicular CD; which will be the mean proportional between AC and CB, or M and N.



To find two Mean Proportionals between two given extremes. Multiply each extreme by the ſquare of the other, viz, the greater extreme by the ſquare of the leſs, and the leſs extreme by the ſquare of the greater; then extract the cube root out of each product, and the two roots will be the two mean proportionals ſought. That is, $\sqrt[3]{a^2b}$ and $\sqrt[3]{ab^2}$ are the two means between a and b. So, between 2 and 16, the two mean proportionals are 4 and 8; for $\sqrt[3]{2^2 \times 16} = \sqrt[3]{64} = 4$, and $\sqrt[3]{2 \times 16^2} = \sqrt[3]{512} = 8$.

In a ſimilar manner we proceed for three means, or four means, or five means, &c. From all which it appears that the ſeries of the ſeveral numbers of mean proportionals between a and b will be as follows: viz,

one mean,	$\sqrt{ab}$;
two means,	$\sqrt[3]{a^2b}$, $\sqrt[3]{ab^2}$;
three means,	$\sqrt[4]{a^3b}$, $\sqrt[4]{a^2b^2}$, $\sqrt[4]{ab^3}$;
four means,	$\sqrt[5]{a^4b}$, $\sqrt[5]{a^3b^2}$, $\sqrt[5]{a^2b^3}$; $\sqrt[5]{ab^4}$;
five means,	$\sqrt[6]{a^5b}$, $\sqrt[6]{a^4b^2}$, $\sqrt[6]{a^3b^3}$, $\sqrt[6]{a^2b^4}$, $\sqrt[6]{ab^5}$;
&c,	&c.

Harmonical MEAN, is double a fourth proportional to the ſum of the extremes, and the two extremes themſelves a and b: thus, as $a + b : a :: 2b : \frac{2ab}{a+b} = m$ the harmonical mean between a and b. Or it is the reciprocal of the arithmetical mean between the reciprocals of the given extremes; that is, take the reciprocals of the extremes a and b, which will be $\frac{1}{a}$ and $\frac{1}{b}$; then take the arithmetical mean between theſe reciprocals, or half their ſum, which will be $\frac{1}{2a} + \frac{1}{2b}$ or $\frac{a+b}{2ab}$; laſtly, the reciprocal of this is $\frac{2ab}{a+b} = m$ the harmonical mean: for, arithmeticals and harmonicals are mutually reciprocals of each other;

ſo that if a, m, b, &c be arithmeticals,

then ſhall $\frac{1}{a}$, $\frac{1}{m}$, $\frac{1}{b}$, &c be harmonicals;

or if the former be harmonicals, the latter will be arithmeticals.

For example, to find a harmonical mean between 2 and 6; here $a = 2$, and $b = 6$; therefore $\frac{2ab}{a+b} = \frac{2 \times 2 \times 6}{2+6} = \frac{24}{8} = 3 = m$ the harmonical mean ſought between 2 and 6.

In the 3d book of Pappus's Mathematical Collections we have a very good tract on all the three ſorts of mean proportionals, beginning at the 5th propoſition. He obſerves, that the Ancients could not reſolve, in a geometrical way, the problem of finding two mean proportionals; and becauſe it is not eaſy to deſcribe the conic ſections in plano, for that purpoſe, they contrived eaſy and convenient inſtruments, by which they obtained good mechanical conſtructions of that problem; as appears by their writings; as in the Meſolabe of Eratoſthenes, of Philo, with the Mechanics and Catapultics of Hero. For theſe, rightly deeming the problem a ſolid one, effected the conſtruction only by inſtruments, and Apollonius Pergæus by means of the conic ſections; which others again performed by the *loci ſolidi* of Ariſtæus; alſo Nicomedes ſolved it by the conchoid, by means of which

which likewiſe he triſected an angle: and Pappus himſelf gave another ſolution of the ſame problem.

Pappus adds definitions of the three foregoing different ſorts of means, with many problems and properties concerning them, and, among others, this curious ſimilarity of them, viz, a, m, b, being three continued terms, either arithmeticals, geometricals, or harmonicals; then in the

Arithmeticals, $a : a :: a - m : m - b$;
Geometricals, $a : m :: a - m : m - b$;
Harmonicals, $a : b :: a - m : m - b$.

MEAN-*and-Extreme Proportion*, or *Extreme-and-Mean Proportion*, is when a line, or any quantity is ſo divided, that the leſs part is to the greater, as the greater is to the whole.

MEAN *Anomaly*, of a planet, is an angle which is always proportional to the time of the planet's motion from the aphelion, or perihelion, or proportional to the area deſcribed by the radius vector; that is, as the whole periodic time in one revolution of the planet, is to the time paſt the aphelion or perihelion, ſo is 360° to the Mean anomaly. See Anomaly.

MEAN *Axis*, in Optics. See AXIS.

MEAN *Conjunction* or *Oppoſition*, is when the mean place of the ſun is in conjunction, or oppoſition, with the mean place of the moon in the ecliptic.

MEAN *Diameter*, in Gauging, is a Mean between the diameters at the head and bung of a caſk.

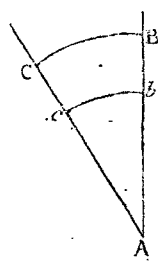
MEAN *Diſtance*, of a Planet from the Sun, is an arithmetical mean between the planet's greateſt and leaſt diſtances; and this is equal to the ſemitranſverſe axis of the elliptic orbit in which it moves, or to the right line drawn from the ſun or focus to the extremity of the conjugate axis of the ſame.

MEAN *Motion*, is that by which a planet is ſuppoſed to move equably in its orbit; and it is always proportional to the time.

MEAN *Time*, or Equal time, is that which is meaſured by an equable motion, as a clock; as diſtinguiſhed from apparent time, ariſing from the unequal motion of the earth or ſun.

MEASURE, denotes any quantity, aſſumed as unity, or one, to which the ratio of other homogeneous or like quantities may be expreſſed.

MEASURE *of an Angle*, is an arc of a circle deſcribed from the angular point as a centre, and intercepted between the legs or ſides of the angle: and it is uſual to eſtimate and expreſs the Meaſure of the angle by the number of degrees and parts contained in that arc, of which 360 make up the whole circumference. So, the meaſure of the angle BAC, is the arc BC to the radius AB, or the arc *bc* to the radius *Ab*.



Hence, a right angle is meaſured by a quadrant, or 90 degrees; and any angle, as BAC, is in proportion to a right angle, as the arc BC is to a quadrant, or as the degrees in BC are to 90 degrees.

Common MEASURE. See COMMON *Meaſure*.

MEASURE *of a Figure*, or Plane Surface, is a ſquare inch, or ſquare foot, or ſquare yard, &c, that is, a ſquare whoſe ſide is an inch, or a foot, or a yard, or ſome other determinate length; and this ſquare is called the *meaſuring unit*.

MEASURE *of a Line*, is any right line taken at pleaſure, and conſidered as unity; as an inch, or a foot, or a yard, &c.

Line of MEASURES. See LINE *of Meaſures*.

MEASURE *of a Maſs*, or *Quantity of Matter*, is its weight.

MEASURE *of a Number*, is any number that divides it, without leaving a remainder. So, 2 is a Meaſure of 4, of 8, or of any even number; and 3 is a Meaſure of 6, or of 9, or of 12, &c.

MEASURE *of a Ratio*, is its logarithm, in any ſyſtem of logarithms; or it is the exponent of the power to which the ratio is equal, the exponent of ſome given ratio being aſſumed as unity. So, if the logarithm or Meaſure of the ratio of 10 to 1, be aſſumed equal to 1; then the Meaſure of the ratio of 100 to 1, will be 2, becauſe 100 is $= 10^2$, or becauſe 100 to 1 is in the duplicate ratio of 10 to 1; and the Meaſure of the ratio of 1000 to 1, will be 3, becauſe 1000 is $= 10^3$, or becauſe 1000 to 1 is triplicate of the ratio of 10 to 1.

MEASURE *of a Solid*, is a cubic inch, or cubic foot, or cubic yard, &c; that is, a cube whoſe ſide is an inch, or a foot, or a yard, &c.

MEASURE *of a Superficies*, the ſame as the Meaſure of a figure.

MEASURE *of Velocity*, is the ſpace uniformly paſſed over by a moving body in a given time.

Univerſal or *Perpetual* MEASURE, is a kind of Meaſure unalterable by time or place, to which the Meaſures of different ages and nations might be reduced, and by which they may be compared and eſtimated. Such a Meaſure would be very uſeful, if it could be attained; ſince, being uſed at all times, and in all places, a great deal of confuſion and error would be avoided.

Huygens, in his Horol. Oſcil. propoſes, for this purpoſe, the length of a pendulum that ſhould vibrate ſeconds, meaſured from the point of ſuſpenſion to the point of oſcillation: the 3d part of ſuch a pendulum to be called horary foot, and to ſerve as a ſtandard to which the Meaſure of all other feet might be referred. Thus, for inſtance, the proportion of the Paris foot to the horary foot, would be that of 864 to 881; becauſe the length of 3 Paris feet is 864 half lines, and the length of a pendulum, vibrating ſeconds, contains 881 half lines. But this Meaſure, in order to its being univerſal, ſuppoſes that the action of gravity is the ſame on every part of the earth's ſurface, which is contrary to fact; for which reaſon it would really ſerve only for places under the ſame parallel of latitude: ſo that, if every different latitude were to have its foot equal to the 3d part of the pendulum vibrating ſeconds there, any latitude would ſtill have a different length of foot. And beſides, the difficulty of meaſuring exactly the diſtance between the centres of motion and oſcillation are ſuch, that hardly any two meaſurers would make it the ſame quantity.

M. Mouton, canon of Lyons, has alſo a treatiſe *De Menſura poſteris tranſmittenda*.

Since that time various other expedients have been propoſed for eſtabliſhing an univerſal Meaſure, but hitherto

hitherto without the perfect effect. In 1779, a method was propoſed to the Society of Arts, &c, by a Mr. Hatton, in conſequence of a premium, which had been 4 years advertiſed by that inſtitution, of a gold medal, or 100 guineas, 'for obtaining invariable ſtandards for weights and Meaſures, communicable at all times and to all nations.' Mr. Hatton's plan conſiſted in the application of a moveable point of ſuſpenſion to one and the ſame pendulum, in order to produce the full and abſolute effect of two pendulums, the difference of whoſe lengths was the intended Meaſure. Mr. Whitehurſt much improved upon this idea, by very curious and accurate machinery, in his tract publiſhed 1787, intitled 'An Attempt towards obtaining invariable Meaſures of Length, Capacity, and Weight, from the Menſuration of time, &c. Mr. Whitehurſt's plan is, to obtain a Meaſure of the greateſt length that conveniency will permit, from two pendulums whoſe vibrations are in the ratio of 2 to 1, and whoſe lengths coincide with the Engliſh ſtandard in whole numbers. The numbers he has choſen ſhew great ingenuity. On a ſuppoſition that the length of a ſeconds pendulum, in the latitude of London, is 39·2 inches, the length of one vibrating 42 times in a minute, muſt be 80 inches; and of another vibrating 84 times in a minute, muſt be 20 inches; their difference, 60 inches or 5 feet, is his ſtandard Meaſure. By his experiments, however, the difference in the lengths of the two pendulums was found to be 59·892 inches inſtead of 60, owing to the error in the aſſumed length of the ſeconds pendulum, 39·2 inches being greater than the truth. Mr. Whitehurſt has fully accompliſhed his deſign, and ſhewn how an invariable ſtandard may, at all times, be found for the ſame latitude. He has alſo aſcertained a fact, as accurately as human powers ſeem capable of aſcertaining it, of great conſequence in natural philoſophy. The difference between the lengths of the rods of two pendulums whoſe vibrations are known, is a datum from which may be derived the true length of pendulums, the ſpaces through which heavy bodies fall in a given time, with many other particulars relative to the doctrine of gravitation, the figure of the earth, &c, &c. The reſult deduced from this experiment is, that the length of a ſeconds pendulum, vibrating in a circular arc of 3° 20′, is 39·119 inches very nearly; but vibrating in the arc of a cycloid it would be 39·136 inches; and hence, heavy bodies will fall, in the firſt ſecond of their deſcent, 16·094 feet, or 16 feet 1⅛ inch, very nearly.

It is ſaid, the French philoſophers have a plan in contemplation, to take for a univerſal Meaſure, the length of a whole meridian circle of the earth, and take all other Meaſures from ſub-diviſions of that; which will be a very good way.—Other projects have alſo been deviſed, but of little or no conſideration.

MEASURE, in a legal, commercial, and popular ſenſe, denotes a certain quantity or proportion of any thing, bought, ſold, valued, or the like.

The regulation of weights and Meaſures ought to be univerſally the ſame throughout the nation, and indeed all nations; and they ſhould therefore be reduced to ſome fixed rule or ſtandard.

Meaſures are various, according to the various kinds or dimenſions of the things meaſured. Hence ariſe *Lineal* or *Longitudinal* MEASURES, for lines or lengths:

Square MEASURES, for areas or ſuperficies: and

Solid or *Cubic* MEASURES, for the ſolid contents and capacities of bodies.

The ſeveral Meaſures uſed in England, are as in the following Tables:

1. *Engliſh Long Meaſure.*

Barley Corns						
3 =	1 Inch					
36 =	12 =	1 Foot				
108 =	36 =	3 =	1 Yard			
594 =	198 =	16½ =	5½ =	1 Pole		
23760 =	7920 =	660 =	220 =	40 =	1 Furlong	
190082 =	63360 =	5280 =	1760 =	320 =	8 =	1 Mile

Alſo, 4 Inches = 1 Hand
6 Feet, or 2 yds = 1 Fathom
3 Miles = 1 League
60 Nautical or Geograph. Miles = 1 Degree
or 69½ Statute Miles = 1 Degree nearly
360 Degrees, or 25000 Miles nearly = the Circumference of the Earth.

2. *Cloth Meaſure.*

Inches				
2¼ =	1 Nail			
9 =	4 =	1 Quarter		
36 =	16 =	4 =	1 Yard	
27 =	12 =	3 =	1 Ell Flemiſh	
45 =	20 =	5 =	1 Ell Engliſh	
54 =	24 =	6 =	1 Ell French.	

3. *Square Meaſure.*

Inches			
144 =	1 Foot		
1296 =	9 =	1 Yard	
39204 =	272¼ =	30¼ =	1 Pole
1568160 =	10890 =	1210 =	40 = 1 Rood
6272640 =	43560 =	4840 =	160 = 4 = 1 Acre.

4. *Solid*, or *Cubical Meaſure.*

Inches		
1728 =	1 Foot	
46656 =	27 =	1 Yard.

5. *Wine Meaſure.*

Pints						
2 =	1 Quart					
8 =	4 =	1 Gallon = 231 Cubic Inches.				
336 =	168 =	42 =	1 Tierce			
504 =	252 =	63 =	1½ =	1 Hogſhead		
672 =	336 =	84 =	2 =	1½ =	1 Puncheon	
1008 =	504 =	126 =	3 =	2 =	1½ =	1 Pipe
2016 =	1008 =	252 =	6 =	4 =	3 =	2 = 1 Tun.

Alſo, 231 Cubic Inches = 1 Gallon
10 Gallons = 1 Anker
18 Gallons = 1 Runlet
31½ Gallons = 1 Barrel.

6. *Ale*

6. *Ale and Beer Measure.*

Pints.

2 =	1 Quart.						
8 =	4 =	1 Gallon = 282 Cubic Inches.					
72 =	36 =	9 =	1 Firkin.				
144 =	72 =	18 =	2 =	1 Kilderkin.			
288 =	144 =	36 =	4 =	2 =	1 Barrel.		
432 =	216 =	54 =	6 =	3 =	$1\frac{1}{2}$ =	1 Hogſhead.	
576 =	288 =	72 =	8 =	4 =	2 =	$1\frac{1}{3}$ =	1 Puncheon.
864 =	432 =	108 =	12 =	6 =	3 =	2 =	$1\frac{1}{2}$ = 1 Butt.

Note, The Ale gallon contains 282 cubic inches.

7. *Dry Measure.*

Pints.

8 =	1 Gallon = $268\frac{4}{5}$ Cubic Inches.					
16 =	2 =	1 Peck.				
64 =	8 =	4 =	1 Buſhel.			
256 =	32 =	16 =	4 =	1 Coom.		
512 =	64 =	32 =	8 =	2 =	1 Quarter.	
2560 =	320 =	160 =	40 =	10 =	5 =	1 Wey.
5120 =	640 =	320 =	80 =	20 =	10 =	2 = 1 Laſt.

Alſo, $268\frac{4}{5}$ Cubic Inches = 1 Gallon.
and 36 Buſhels of Coals = 1 Chaldron.

8. *Proportions of the Long Meaſures of ſeveral Nations to the Engliſh Foot.*

		Thouſandth Parts.	Inches.
Engliſh	foot	1000	12·000
Paris	foot	$1065\frac{3}{4}$	12·792

MEASURING, the ſame as MENSURATION, which ſee.

MECHANICS, a mixed mathematical ſcience, that treats of forces, motion, and moving powers, with their effects in machines, &c. The ſcience of Mechanics is diſtinguiſhed, by Sir Iſaac Newton, into Practical and Rational: the former treats of the Mechanical Powers, and of their various combinations; the latter, or Rational Mechanics, comprehends the whole theory and doctrine of forces, with the motions and effects produced by them.

That part of Mechanics, which treats of the weight,

gravity, and equilibrium of bodies and powers, is called Statics; as diſtinguiſhed from that part which conſiders the Mechanical powers, and their application, which is properly called Mechanics.

Some of the principles of Statics were eſtabliſhed by Archimedes, in his Treatiſe on the Centre of Gravity of Plane Figures: beſides which, little more upon Mechanics is to be found in the writings of the Ancients, except what is contained in the 8th book of Pappus's Mathematical Collections, concerning the five Mechanical Powers. Galileo laid the beſt foundation of Mechanics, when he inveſtigated the deſcent of heavy bodies; and ſince his time, by the aſſiſtance of the new methods of computation, a great progreſs has been made, eſpecially by Newton, in his Principia, which is a general treatiſe on Rational and Phyſical Mechanics, in its largeſt extent. Other writers on this ſcience, or ſome branch of it, are, Guido Ubaldus, in his Liber Mechanicorum; Torricelli, Libri de Motu Gravium naturaliter Deſcendentium & Projectorum; Balianus, Tractatus de Motu naturali Gravium; Huygens, Horologium Oſcillatorium, and Tractatus de Motu Corporum ex Percuſſione; Leibnitz, Reſiſtentia Solidorum in Acta Eruditor. an. 1684; Guldinus, De Centro Gravitatis; Wallis, Tractatus de Mechanica; Varignon, Projet d'une Nouvelle Mechanique, and his papers in the Memoir. Acad. an. 1702; Borelli, Tractatus De Vi Percuſſionis, De Motionibus Naturalibus a Gravitate pendentibus, and De Motu Animalium; De Chales, Treatiſe on Motion; Pardies, Diſcourſe of Local Motion; Parent, Elements of Mechanics and Phyſics; Caſatus, Mechanica; Oughtred, Mechanical Inſtitutions; Rohault, Tractatus de Mechanica; Lamy, Mechanique; Keill, Introduction to true Philoſophy; De la Hire, Mechanique; Mariotte, Traité du Choc des Corps; Ditton, Laws of Motion; Herman, Phoronomia; Graveſande, Phyſics: Euler, Tractatus de Motu; Muſſchenbroek, Phyſics; Boſſu, Mechanique; Deſaguliers, Mechanics; Rowning, Natural Philoſophy; Emerſon, Mechanics; Parkinſon, Mechanics; La Grange, Mechanique Analytique; Nicholſon, Introduction to Natural Philoſophy; Enfield, Inſtitutes of Natural Philoſophy, &c, &c. As to the Deſcription of Machines, ſee Strada, Zeiſingius, Beſſon, Auguſtine de Ramellis, Boetler, Leopold, Sturmy, Perrault, Limberg, Emerſon, Royal Academy of Sciences, &c.

In treating of machines, we ſhould conſider the weight that is to be raiſed, the power by which it is to be raiſed, and the inſtrument or engine by which this effect is to be produced. And, in treating of theſe, there are two principal problems that preſent themſelves: the firſt is, to determine the proportion which the power and weight ought to have to each other, that they may juſt be in equilibrio; the ſecond is, to determine what ought to be the proportion between the power and weight, that a machine may produce the greateſt effect in a given time. All writers on Mechanics treat on the firſt of theſe problems, but few have conſidered the ſecond, though not leſs uſeful than the other.

As to the firſt problem, this general rule holds in all powers; namely, that when the power and weight are reciprocally proportional to the diſtances of the directions in which they act, from the centre of motion; or when the product of the power by the diſtance of its direction, is equal to the product of the weight by the diſtance of its direction; this is the caſe in which the power and weight ſuſtain each other, and are in equilibrio; ſo that the one would not prevail over the other, if the engine were at reſt; and if it were in motion, it would continue to proceed uniformly, if it were not for the friction of its parts, and other reſiſtances. And, in general, the effect of any power, or force, is as the product of that force multiplied by the diſtance of its direction from the centre of motion, or the product of the power and its velocity when in motion, ſince this velocity is proportional to the diſtance from that centre.

The ſecond general problem in Mechanics, is, to determine the proportion between the power and weight, ſo that when the power prevails, and the machine is in motion, the greateſt effect poſſible may be produced by it in a given time. It is manifeſt, that this is an enquiry of the greateſt importance, though few have treated of it. When the power is only a little greater than what is ſufficient to ſuſtain the weight, the motion uſually is too ſlow; and though a greater weight be raiſed in this caſe, it is not ſufficient to compenſate for the loſs of time. On the other hand, when the power is much greater than what is ſufficient to ſuſtain the weight, this is raiſed in leſs time; but it may happen that this is not ſufficient to compenſate for the loſs ariſing from the ſmallneſs of the load. It ought therefore to be determined when the product of the weight multiplied by its velocity, is the greateſt poſſible; for this product meaſures the effect of the engine in a given time, which is always the greater in proportion both as the weight is greater, and as its velocity is greater. For ſome calculations on this problem, ſee Maclaurin's Account of Newton's Diſcoveries, p. 171, &c; alſo his Fluxions, art. 908 &c. And, for the various properties in Mechanics, ſee the ſeveral terms Motion, Force, Mechanical Powers, Lever, &c.

MECHANIC, or Mechanical, ſomething relating to Mechanics, or regulated by the nature and laws of motion.

Mechanical is alſo uſed in Mathematics, to ſignify a conſtruction or proof of ſome problem, not done in an accurate and geometrical manner, but coarſely and unartfully, or by the aſſiſtance of inſtruments; as are moſt problems relating to the duplicature of the cube, and the quadrature of the circle.

Mechanical *Affections*, ſuch properties in matter, as reſult from their figure, bulk, and motion.

Mechanical *Cauſes*, are ſuch as are founded on Mechanical Affections.

Mechanical *Curve*, called alſo *Tranſcendental*, is one whoſe nature cannot be expreſſed by a finite Algebraical equation.

Mechanical *Philoſophy*, alſo called the *Corpuſcular Philoſophy*, is that which explains the phenomena of nature, and the operations of corporeal things, on the principles of Mechanics; viz, the motion, gravity, figure, arrangement, diſpoſition, greatneſs,

or ſmallneſs of the parts which compoſe natural bodies.

MECHANICAL *Solution*, of a Problem, is either when the thing is done by repeated trials, or when the lines uſed in the ſolution are not truly geometrical, or by organical conſtruction.

MECHANICAL *Powers*, are certain ſimple machines which are uſed for raiſing greater weights, or overcoming greater reſiſtances than could be effected by the natural ſtrength without them.

Theſe ſimple machines are uſually accounted ſix in number, viz, the Lever, the Wheel and Axle, or Axis in Peritrochio, the Pulley, the Inclined Plane, the Wedge, and the Screw. Of the various combinations of theſe ſimple powers do all engines, or compound machines, conſiſt: and in treating of them, ſo as to ſettle their theory and properties, they are conſidered as mathematically exact, or void of weight and thickneſs, and moving without friction. See the properties and demonſtrations of each of theſe under the ſeveral words LEVER, &c. To which may be added the following general obſervations on them all, in a connective way.

1. A *Lever*, the moſt ſimple of all the mechanic powers, is an engine chiefly uſed to raiſe large weights to ſmall heights; ſuch as a handſpike, when of wood; and a crow, when of iron. In theory, a lever is conſidered as an inflexible line, like the beam of a balance, and ſubject to the ſame proportions; only that the power applied to it, is commonly an animal power; and from the different ways of uſing it, or applying it, it is called a lever of the firſt, ſecond, or third kind: viz, of the 1ſt kind, when the weight is on one ſide of the prop, and the power on the other; of the 2d kind, when the weight is between the prop and the power; and of the 3d kind, when the power is between the prop and the weight.

Many of the inſtruments in common uſe, are levers of one of the three kinds; thus, pincers, ſheers, forceps, ſnuffers, and ſuch like, are compounded of two levers of the firſt kind; for the joint about which they move, is the fulcrum, or centre of motion; the power is applied to the handles, to preſs them together; and the weight is the body which they pinch or cut. The cutting knives uſed by druggiſts, patten-makers, block-makers, and ſome other trades, are levers of the 2d kind: for the knife is fixed by a ring at one end, which makes the fulcrum, or fixed point; the other end is moved by the hand, or power; and the body to be cut, or the reſiſtance to be overcome, is the weight. Doors are levers of the 2d kind; the hinges being the centre of motion; the hand applied to the lock is the power; while the door or weight lies between them. A pair of bellows conſiſts of two levers of the 2d kind; the centre of motion is where the ends of the boards are fixed near the pipe; the power is applied at the handles; and the air preſſed out from between the boards, by its reſiſtance, acts againſt the middle of the boards like a weight. The oars of a boat are levers of the 2d kind: the fixed point is the blade of the oar in the water; the power is the hand acting at the other end; and the weight to be moved is the boat. And the ſame of the rudder of a veſſel. Spring ſheers and tongs are levers of the 3d kind; where the centre of motion is at the bow-ſpring at one end; the weight or reſiſtance is acted on by the other end; and the hand or power is applied between the ends. A ladder reared by a man againſt a wall, is a lever of the 3d kind: and ſo are alſo almoſt all the bones and muſcles of animals.

In all levers, the effect of any power or weight, is both proportional to that power or weight, and alſo to its diſtance from the centre of motion. And hence it is that, in raiſing great weights by a lever, we chuſe the longeſt levers; and alſo reſt it upon a point as far from the hand or power, and as near to the weight, as poſſible. Hence alſo there will be an equilibrium between the power and weight, when thoſe two products are equal, viz, the power multiplied by its diſtance, equal to the weight multiplied by its diſtance; when, alſo, the weight and power are to each other reciprocally as their diſtances from the prop or fixed point.

2. The Axis in Peritrochio, or Wheel and Axle, is a ſimple engine conſiſting of a wheel fixed upon the end of an axle, ſo that they both turn round together in the ſame time. This engine may be referred to the lever: for the centre of the axis, or wheel, is the fixed point; the radius of the wheel is the diſtance of the power, acting at the circumference of the wheel, from that point; and the radius of the axle is the diſtance of the weight from the ſame point. Hence the effect of the power, independent of its own natural intenſity, is as the radius of the wheel; and the effect of the weight is as the radius of the axle: ſo that the two will be in æquilibrio, when the two products are equal, which are made by multiplying each of theſe, the weight and power, by the radius, or diſtance at which it acts; and then alſo, the weight and power are reciprocally proportional to thoſe radii.

In practice, the thickneſs of the rope, that winds upon the axle, and to which the weight is faſtened, is to be conſidered: which is done, by adding half its thickneſs to the radius of the axis, for its diſtance from the fixed point, when there is only one fold of rope upon the axle; or as many times the thickneſs as there are folds, wanting only one half when there are ſeveral folds of the rope, one over another: which is the reaſon that more power muſt be applied when the axis is thus thickened; as often happens in drawing water from a deep and narrow well, over which a long axle cannot be placed.

If the rope to which the power is faſtened, be ſucceſſively applied to different wheels, whoſe diameters are larger and larger; the axis will be turned with ſtill more and more eaſe, unleſs the intenſity of the power be diminiſhed in the ſame proportion; and if ſo, the axis will always be drawn with the ſame ſtrength by a power continually diminiſhing. This is practiſed in ſpring clocks and watches; where the ſpiral ſpring, which is ſtrongeſt in its action when firſt wound up, draws the fuzee, or continued axis in peritrochio, firſt by the ſmaller wheels, and as it unbends and becomes weak, draws at the larger wheels, in ſuch manner that the watch work is always carried round with the ſame force.

As a very ſmall axis would be too weak for very great weights, or a large wheel would be expenſive as well.

well as cumberſome, and take more room than perhaps can be ſpared for it; therefore, that the action of the power may be increaſed, without incurring either of thoſe inconveniences, a compound Axis in Peritrochio is uſed, which is effected by combining wheels and axles by means of pinions, or ſmall wheels, upon the axles, the teeth of which take hold of teeth made in the large wheels; as is ſeen in clocks, jacks, and other compound machines. And in ſuch a combination of wheels and axles, the effect of the power is increaſed in the ratio of the continual product of all the axles, or ſmall wheels, to that of all the large ones. Thus, if there be two ſmall wheels and an axle, turning three large wheels; the axle being 2 inches diameter, and each of the ſmall wheels 4 inches, while the large ones are 2 feet or 24 inches diameter; then $2 \times 4 \times 4 = 32$ is the continual product of the ſmall diameters, and $24 \times 24 \times 24 = 13824$ is that of the large ones; therefore 13824 to 32, or 432 to 1, is the ratio in which the power is increaſed: and if the power be a man, whoſe natural ſtrength is equal, ſuppoſe, to 150 pounds weight, then $432 \times 150 = 64800$lb, or 28 ton 18 cwt 64lb, is the weight he would be able to balance, ſuſpended about the axle.

3. *A Single Pulley*, is a ſmall wheel, moveable round an axis, called its centre pin; which of itſelf is not properly one of the mechanical powers, becauſe it produces no gain of power; for, as the weight hangs by one end of the cord that paſſes over the pulley, and the power acts at the other end of the ſame, theſe act at equal diſtances from the centre or axis of motion, and conſequently the power is equal to the weight when in equilibrio. So that the chief uſe of the ſingle pulley is to change the direction of the power from upwards to downwards, &c, and to convey bodies to a great height or diſtance, without a perſon moving from his place.

But by combining ſeveral ſingle pulleys together, a conſiderable gain of power is made, and that in proportion to the additional number of ropes made to paſs over them; and yet it enjoys at the ſame time the properties of a ſingle pulley, by changing the direction of the action in any manner.

4. *The Inclined Plane*, is made by planks, bars, or beams, laid aſlope; by which, large and heavy bodies may be more eaſily raiſed or lowered, by ſliding them up or down the plane; and the gain in power is in proportion as the length of the plane to its height, or as radius to the ſine of the angle of inclination of the plane with the horizon.

In drawing a weight up an inclined plane, the power acts to the greateſt advantage, when its direction is parallel to the plane.

5. *The Wedge*, which reſembles a double inclined plane, is very uſeful to drive in below very heavy weights to raiſe them but a ſmall height, alſo in cleaving and ſplitting blocks of wood, and ſtone &c; and the power gained, is in proportion of the ſlant ſide to half the thickneſs of the back. So that, if the back of a wedge be 2 inches thick, and the ſide 20 inches long, any weight preſſing on the back will balance 20 times as much acting on the ſide. But the great advantage of a wedge lies in its being urged, not by preſſure, but uſually by percuſſion, as the blow of a hammer or mallet; by which means a wedge may be driven in below, and ſo be made to lift, almoſt any the greateſt weight, as the largeſt ſhip, by a man ſtriking the back of a wedge with a mallet.

To the wedge may be referred the axe or hatchet, the teeth of ſaws, the chiſel, the augur, the ſpade and ſhovel, knives and ſwords of all kinds, as alſo the bodkin and needle, and in a word all ſorts of inſtruments which, beginning from edges or points, become gradually thicker as they lengthen; the manner in which the power is applied to ſuch inſtruments, being different according to their different ſhapes, and the various uſes for which they have been contrived.

6. *The Screw*, is a kind of perpetual or endleſs Inclined Plane; the power of which is ſtill farther aſſiſted by the addition of a handle or lever, where the power acts; ſo that the gain in power, is in the proportion of the circumference deſcribed or paſſed through by the power, to the diſtance between thread and thread in the ſcrew.

The uſes to which the ſcrew is applied, are various; as, the preſſing of bodies cloſe together; ſuch as the preſs for napkins, for bookbinders, for packers, hot-preſſers, &c.

In the ſcrew, and the wedge, the power has to overcome both the weight, and alſo a very great friction in thoſe machines; ſuch indeed as amounts ſometimes to as much as the weight to be raiſed, or more. But then this friction is of uſe in retaining the weight and machine in its place, even after the power is taken off.

If machines or engines could be made without friction, the leaſt degree of power added to that which balances the weight, would be ſufficient to raiſe it. In the lever, the friction is little or nothing; in the wheel and axle, it is but ſmall; in pulleys, it is very conſiderable; and in the inclined plane, wedge, and ſcrew, it is very great.

It is a general property in all the Mechanic powers, that when the weight and power are regulated ſo as to balance each other, in every one of theſe machines, if they be then put in motion, the power and weight will be to each other reciprocally as the velocities of their motion, or the power is to the weight as the velocity of the weight is to the velocity of the power; ſo that their two momenta are equal, viz, the product of the power multiplied by its velocity, equal to the product of the weight multiplied by its velocity. And hence too, univerſally, what is gained in power, is loſt in time; for the weight moves as much ſlower as the power is ſmaller.

Hence alſo it is plain, that the force of the power is not at all increaſed by engines; only the velocity of the weight, either in lifting or drawing, is ſo diminiſhed by the application of the inſtrument, as that the momentum of the weight is not greater than the force of the power. Thus, for inſtance, if any force can raiſe a pound weight with a given velocity, it is impoſſible by any engine to raiſe 2 pound weight with the ſame velocity: but by an engine it may be made to raiſe 2 pound weight with half the velocity, or even 1000 times the weight with the 1000th part of the velocity.

See Maclaurin's Account of Newton's Philoſ. Diſcov. book 2, chap. 3; Hamilton's Philoſ. Eſſ. 1; Philoſ. Tranſ. 53, pa. 116; or Landen's Memoirs, vol. 1, pa. 1.

MECHANISM, either the conſtruction or the machinery employed in any thing; as the Mechaniſm of the barometer, of the microſcope, &c.

MEDIUM, the ſame as mean, either arithmetical, geometrical, or harmonical.

MEDIUM denotes alſo that ſpace, or region, or fluid, &c, through which a body paſſes in its motion towards any point. Thus, the air, or atmoſphere, is the medium in which birds and beaſts live and move, and in which a projectile moves; water is the medium in which fiſhes move; and æther is a ſuppoſed ſubtile Medium in which the planets move. Glaſs is alſo called a Medium, being that through which the rays of light move and paſs.

Mediums reſiſt the motion of bodies moving through them, in proportion to their denſity or ſpecific gravity.

Subtile or *Ætherial* MEDIUM, is an univerſal one whoſe exiſtence is by Newton rendered probable. He makes it univerſal; and vaſtly more rare, ſubtile, elaſtic, and active than air; and by that means freely permeating the pores and interſtices of all other Mediums, and diffuſing itſelf through the whole creation. By the intervention of this ſubtile Medium he thinks it is that moſt of the great phenomena of nature are effected. See ÆTHER.

This Medium it would ſeem he has recourſe to, as the firſt and moſt remote phyſical ſpring, and the ultimate of all natural cauſes. By the vibrations of this Medium, he ſuppoſes that heat is propagated from lucid bodies; as alſo the intenſeneſs of heat increaſed and preſerved in hot bodies, and from them communicated to cold ones.

By this Medium, he ſuppoſes that light is reflected, inflected, refracted, and put alternately into fits of eaſy reflection and tranſmiſſion; which effects he alſo elſewhere aſcribes to the power of attraction; ſo that it would ſeem, this Medium is the ſource and cauſe even of attraction itſelf.

Again, this Medium being much rarer within the heavenly bodies, than in the heavenly ſpaces, and growing denſer as it recedes farther from them, he ſuppoſes this is the cauſe of the gravitation of theſe bodies towards each other, and of the parts towards the bodies.

Again, from the vibrations of this ſame Medium, excited in the bottom of the eye by the rays of light, and thence propagated through the capillaments of the optic nerves into the ſenſorium, he ſuppoſes that viſion is performed: and ſo likewiſe hearing, from the vibrations of this or ſome other Medium, excited in the auditory nerves by the tremors of the air, and propagated through the capillaments of thoſe nerves into the ſenſorium: and ſo of the other ſenſes.

And again, he conceives that muſcular motion is performed by the vibrations of the ſame Medium, excited in the brain at the command of the will, and thence propagated through the capillaments of the nerves into the muſcles; and thus contracting and dilating them.

The elaſtic force of this Medium, he ſhews, muſt be prodigiouſly great. Light moves at the rate of conſiderably more than 10 millions of miles in a minute; yet the vibrations and pulſations of this Medium, to cauſe the fits of eaſy reflection and tranſmiſſion, muſt be ſwifter than light, which is yet 7 hundred thouſand times ſwifter than ſound. The elaſtic force of this Medium, therefore, in proportion to its denſity, muſt be above 490000 million of times greater than the elaſtic force of the air, in proportion to its denſity; the velocities and pulſes of the elaſtic Mediums being in a ſubduplicate ratio of the elaſticities, and the rarities of the Mediums, taken together. And thus may it be conceived that the vibration of this Medium is the cauſe alſo of the elaſticity of bodies.

Farther, the particles of this Medium being ſuppoſed indefinitely ſmall, even ſmaller than thoſe of light; if they be likewiſe ſuppoſed, like our air, endued with a repelling power, by which they recede from each other, the ſmallneſs of the particles may exceedingly contribute to the increaſe of the repelling power, and conſequently to that of the elaſticity and rarity of the Medium; by that means fitting it for the free tranſmiſſion of light, and the free motions of the heavenly bodies. In this Medium may the planets and comets roll without any conſiderable reſiſtance. If it be 700,000 times more elaſtic, and as many times rarer, than air, its reſiſtance will be above 600 million times leſs than that of water; a reſiſtance that would cauſe no ſenſible alteration in the motion of the planets in ten thouſand years.

MEGAMETER. See MICROMETER.

MEIBOMIUS (MARCUS), a very learned perſon of the 17th century, of a family in Germany which had long been famous for learned men. He devoted himſelf to literature and criticiſm, but particularly to the learning of the Ancients; as their muſic, the ſtructure of their galleys, &c. In 1652 he publiſhed a collection of ſeven Greek authors, who had written upon Ancient Muſic, to which he added a Latin verſion by himſelf. This work he dedicated to queen Chriſtina of Sweden; in conſequence of which he received an invitation to that Princeſs's court, like ſeveral other learned men, which he accepted. The queen engaged him one day to ſing an air of ancient muſic, while a perſon danced the Greek dances to the ſound of his voice; and the immoderate mirth which this occaſioned in the ſpectators, ſo covered him with ridicule, and diſguſted him ſo vehemently, that he abruptly left the court of Sweden immediately, after heartily battering with his fiſts the face of Bourdelot, the favourite phyſician and buffon to the queen, who had perſuaded her to exhibit that ſpectacle.

Meibomius pretended that the Hebrew copy of the Bible was full of errors, and undertook to correct them by means of a metre, which he fancied he had diſcovered in thoſe ancient writings; but this it ſeems drew upon him no ſmall raillery from the Learned. Nevertheleſs, beſides the work above mentioned, he produced ſeveral others, which ſhewed him to be a good ſcholar; witneſs his Notes upon Diogenes Laertius in Menage's edition; his *Liber de Fabricâ Triremium*, 1671, in which he thinks he diſcovered the

method in which the Ancients diſpoſed their banes of oars; his edition of the Ancient Greek Mythologiſts; and his Dialogues on Proportions, a curious work, in which the interlocutors, or perſons repreſented as ſpeaking, are Euclid, Archimedes, Apollonius, Pappus, Eutocius, Theo, and Hermotimus. This laſt work was oppoſed by Langius, and by Dr. Wallis, in a conſiderable Tract, printed in the firſt volume of his works.

MELODY, is the agreeable effect of different muſical ſounds, ranged or diſpoſed in a proper ſucceſſion, being the effect only of one ſingle part, voice, or inſtrument; by which it is diſtinguiſhed from harmony, which properly reſults from the union of two or more muſical ſounds heard together.

MENISCUS, a lens or glaſs, convex on one ſide, and concave on the other. Sometimes alſo called a Lune or Lunula. See its figure under the article LENS.

To find the Focus of a Meniſcus, the rule is, as the difference between the diameters of the convexity and concavity, is to either of them, ſo is the other diameter, to the focal length, or diſtance of the focus from the Meniſcus. So that, having given the diameter of the convexity, it is eaſy to find that of the concavity, ſo as to remove the focus to any propoſed diſtance from the Meniſcus. For, if D and d be the diameters of the two ſides, and f the focal diſtance; then ſince,

by the rule $D - d : D :: d : f$,
therefore $d : D :: f - d : f$,
or $f - d : f :: d : D$.

Hence, if D the diameter of the concavity be double to d that of the convexity, f will be equal to D, or the focal diſtance equal to the diameter; and therefore the Meniſcus will be equivalent to a plano-convex lens.

Again, if $D = 3d$, or the diameter of the concavity triple to that of the convexity, then will $f = \frac{1}{2}D$, or the focal diſtance equal to the radius of concavity; and therefore the Meniſcus will be equivalent to a lens equally convex on either ſide.

But if $D = 5d$, then will $f = \frac{1}{4}D$; and therefore the Meniſcus will be equivalent to a ſphere.

Laſtly, if $D = d$, then will f be infinite; and therefore a ray falling parallel to the axis, will ſtill continue parallel to it after refraction.

MENSTRUUM, SOLVENT, or DISSOLVENT, any fluid that will diſſolve hard bodies, or ſeparate their parts. Sir Iſaac Newton accounts for the action of Menſtruums from the acids with which they are impregnated; the particles of acids being endued with a ſtrong attractive force, in which their activity conſiſts, and by virtue of which they diſſolve bodies. By this attraction they gather together about the particles of bodies, whether metallic, ſtony, or the like, and adhere very cloſely to them, ſo as ſcarce to be ſeparated from them by diſtillation, or ſublimation. Thus ſtrongly attracting, and gathering together on all ſides, they raiſe, disjoin, and ſhake aſunder the particles of bodies, i. e. they diſſolve them; and by the attractive power with which they ruſh againſt the particles of the bodies, they move the fluid, and ſo excite heat, ſhaking ſome of the particles to that degree, as to convert them into air, and ſo generating bubbles.

Dr. Keill has given the theory or foundation of the action of Menſtruums, in ſeveral propoſitions. See ATTRACTION. From thoſe propoſitions are perceived the reaſons of the different effects of different Menſtruums; why ſome bodies, as metals, diſſolve in a ſaline Menſtruum; others again, as reſins, in a ſulphureous one; &c: particularly why ſilver diſſolves in aqua fortis, and gold only in aqua regis; all the varieties of which are accountable for, from the different degrees of coheſion, or attraction in the parts of the body to be diſſolved, the different diameters and figures of its pores, the different degrees of attraction in the Menſtruum, and the different diameters and figures of its parts.

MENSURABILITY, the fitneſs of a body for being applied, or conformable to a certain meaſure.

MENSURATION, the act, or art, of meaſuring figured extenſion and bodies; or of finding the dimenſions, and contents of bodies, both ſuperficial and ſolid.

Every different ſpecies of Menſuration is eſtimated and meaſured by others of the ſame kind; ſo, the ſolid contents of bodies are meaſured by cubes, as cubic inches, or cubic feet, &c; ſurfaces by ſquares, as ſquare inches, feet, &c; and lengths or diſtances by other lines, as inches, feet, &c.

The contents of rectilinear figures, whether plane or ſolid, can be accurately determined, or expreſſed; but of many curved ones, not. So the quadrature of the circle, and cubature of the ſphere, are problems that have never yet been accurately ſolved. See the various kinds of Menſuration, as well as that of the different figures, under their reſpective terms.

The firſt writers on Geometry were chiefly writers on Menſuration; as Euclid, Archimedes, &c. See QUADRATURE; alſo the Preface to my Menſuration, for the moſt ample information.

MERCATOR (GERARD), an eminent geographer and mathematician, was born in 1512, at Ruremonde in the Low Countries. He applied himſelf with ſuch induſtry to the ſciences of geography and mathematics, that it has been ſaid he often forgot to eat and ſleep. The emperor Charles the 5th encouraged him much in his labours, and the duke of Juliers made him his coſmographer. He compoſed and publiſhed a Chronology; a larger and ſmaller Atlas; and ſome Geographical Tables; beſide other books in Philoſophy and Divinity. He was alſo ſo curious, as well as ingenious, that he engraved and coloured his maps himſelf. He made various maps, globes, and other mathematical inſtruments for the uſe of the emperor; and gave the moſt ample proofs of his uncommon ſkill in what he profeſſed. His method of laying down charts is ſtill uſed, which bear the name of *Mercator's Charts*; alſo a part of navigation is from him called *Mercator's Sailing*.—He died at Duiſbourg in 1594, at 82 years of age.—See MERCATOR's *Chart*, below.

MERCATOR *(Nicholas)*, an eminent mathematician and aſtronomer, whoſe name in High-Dutch was *Hauffman*, was born, about the year 1640, at Holſtein in Denmark. From his works we learn, that he had an early and liberal education, ſuitable to his diſtinguiſhed genius, by which he was enabled to extend his

researches

reſearches into the mathematical ſciences, and to make very conſiderable improvements: for it appears from his writings, as well as from the character given of him by other mathematicians, that his talent rather lay in improving, and adapting any diſcoveries and improvements to uſe, than invention. However, his genius for the mathematical ſciences was very conſpicuous, and introduced him to public regard and eſteem in his own country, and facilitated a correſpondence with ſuch as were eminent in thoſe ſciences, in Denmark, Italy, and England. In conſequence, ſome of his correſpondents gave him an invitation to this country, which he ſome time after accepted, and he afterwards continued in England till his death. He had not been long here before he was admitted F. R. S. and gave frequent proofs of his cloſe application to ſtudy, as well as of his eminent abilities in improving ſome branch or other of the ſciences. But he is charged ſometimes with borrowing the inventions of others, and adopting them as his own. And it appeared upon ſome occaſions that he was not of an over-liberal mind in ſcientific communications. Thus, it had ſome time before him been obſerved, that there was an analogy between a ſcale of logarithmic tangents and Wright's protraction of the nautical meridian line, which conſiſted of the ſums of the ſecants; though it does not appear by whom this analogy was firſt diſcovered. It appears however to have been firſt publiſhed, and introduced into the practice of navigation, by Henry Bond, who mentions this property in an edition of Norwood's Epitome of Navigation, printed about 1645; and he again treats of it more fully in an edition of Gunter's Works, printed in 1653, where he teaches, from this property, to reſolve all the caſes of Mercator's Sailing by the logarithmic tangents, independent of the table of meridional parts. This analogy had only been found to be nearly true by trials, but not demonſtrated to be a mathematical property. Such demonſtration ſeems to have been firſt diſcovered by Mercator, who, deſirous of making the moſt advantage of this and another concealed invention of his in navigation, by a paper in the Philoſophical Tranſactions for June 4, 1666, invites the public to enter into a wager with him on his ability to prove the truth or falſehood of the ſuppoſed analogy. This mercenary propoſal it ſeems was not taken up by any one, and Mercator reſerved his demonſtration. Our author however diſtinguiſhed himſelf by many valuable pieces on philoſophical and mathematical ſubjects. His firſt attempt was, to reduce Aſtrology to rational principles, which proved a vain attempt. But his writings of more particular note, are as follow:

1. *Coſmographia, ſive Deſcriptio Cœli & Terræ in Circulos, qua fundamentum ſterniter ſequentibus ordine Trigonometriæ Sphericorum Logarithmicæ, &c, a Nicolao Hauffman Holſato;* printed at Dantzick, 1651, 12mo.

2. *Rationes Mathematicæ ſubductæ anno* 1653; Copenhagen, in 4to.

3. *De Emendatione annua Diatribæ duæ, quibus exponuntur & demonſtrantur Cycli Solis & Lunæ, &c;* in 4to.

4. *Hypotheſis Aſtronomica nova, et Conſenſus ejus cum Obſervationibus;* Lond. 1664, in folio.

5. *Logarithmotechnia, ſive Methodus Conſtruendi Logarithmos nova, accurata, et facilis; ſcripto antehac communicata anno ſc.* 1667 *nonis Auguſti; cui nunc accedit, Vera Quadratura Hyperbolæ, & Inventio ſummæ Logarithmorum. Auctore Nicolao Mercatore Holſato è Societate Regia. Huic etiam jungitur Michaelis Angeli Riccii Exercitatio Geometrica de Maximis et Minimis, hic ob argumenti præſtantiam & exemplarium raritatem recuſa:* Lond. 1668, in 4to.

6. *Inſtitutionum Aſtronomicarum libri duo, de Motu Aſtrorum communi & proprio, ſecundum hypotheſes veterum & recentiorum præcipuas; deque Hypotheſeon ex obſervatis conſtructione, cum tabulis Tychonianis, Solaribus, Lunaribus, Lunæ-ſolaribus, & Rudolphinis Solis, Fixarum & quinque Errantium, earumque uſu præceptis et exemplis commonſtrato. Quibus accedit Appendix de iis, quæ noviſſimis temporibus cœlitus innotuerunt*: Lond. 1676, 8vo.

7. *Euclidis Elementa Geometrica, novo ordine ac methodo fere, demonſtrata. Una cum Nic. Mercatoris in Geometriam Introductione brevi, qua Magnitudinum Ortus ex geminis Principiis, & Ortarum Affectiones ex ipſa Geneſi derivantur.* Lond. 1678, 12mo.

His papers in the Philoſophical Tranſactions, are,

1. A Problem on ſome Points in Navigation: vol. 1, pa. 215.

2. Illuſtrations of the Logarithmo-technia: vol. 3, pa. 759.

3. Conſiderations concerning his Geometrical and Direct Method for finding the Apogees, Excentricities, and Anomalies of the Planets: vol. 5, pa. 1168.

Mercator died in 1594, about 54 years of age.

MERCATOR's *Chart*, or *Projection*, is a projection of the ſurface of the earth in plano, ſo called from Gerrard Mercator, a Flemiſh Geographer, who firſt publiſhed maps of this ſort in the year 1556; though it was Edward Wright who firſt gave the true principles of ſuch charts, with their application to Navigation, in 1599.

In this chart or projection, the meridians, parallels, and rhumbs, are all ſtraight lines, the degrees of longitude being every where increaſed ſo as to be equal to one another, and having the degrees of latitude alſo increaſed in the ſame proportion; namely, at every latitude or point on the globe, the degrees of latitude, and of longitude, or the parallels, are increaſed in the proportion of radius to the ſine of the polar diſtance, or coſine of the latitude; or, which is the ſame thing, in the proportion of the ſecant of the latitude to radius; a proportion which has the effect of making all the parallel circles be repreſented by parallel and equal right lines, and all the meridians by parallel lines alſo, but increaſing infinitely towards the poles.

From this proportion of the increaſe of the degrees of the meridian, viz, that they increaſe as the ſecant of the latitude, it is very evident that the length of an arch of the meridian, beginning at the equator, is proportional to the ſum of all the ſecants of the latitude, i. e. that the increaſed meridian, is to the true arch of it, as the ſum of all thoſe ſecants, to as many times the radius. But it is not ſo evident that the ſame increaſed meridian is alſo analogous to a ſcale of the logarithmic tangents, which however it is. "It does not appear by whom, nor by what accident, was diſcovered the

analogy between a ſcale of logarithmic tangents and Wright's protraction of the nautical meridian line, which conſiſted of the ſums of the ſecants. It appears however to have been firſt publiſhed, and introduced into the practice of navigation, by Mr. Henry Bond, who mentions this property in an edition of Norwood's Epitome of Navigation, printed about 1645; and he again treats of it more fully in an edition of Gunter's Works, printed in 1653, where he teaches, from this property, to reſolve all the caſes of Mercator's Sailing by the logarithmic tangents, independent of the table of meridional parts. This analogy had only been found however to be nearly true by trials, but not demonſtrated to be a mathematical property. Such demonſtration, it ſeems, was firſt diſcovered by Mr. Nicholas Mercator, which he offered a wager to diſcloſe, but this not being accepted; Mercator reſerved his demonſtration; as mentioned in the account of his life in the foregoing page. The propoſal however excited the attention of mathematicians to the ſubject, and demonſtrations were not long wanting. The firſt was publiſhed about two years after, by James Gregory, in his Exercitationes Geometricæ; from hence, and other ſimilar properties there demonſtrated, he ſhews how the tables of logarithmic tangents and ſecants may eaſily be computed from the natural tangents and ſecants.

"The ſame analogy between the logarithmic tangents and the meridian line, as alſo other ſimilar properties, were afterwards more elegantly demonſtrated by Dr. Halley, in the Philoſ. Tranſ. for Feb. 1696, and various methods given for computing the ſame, by examining the nature of the ſpirals into which the rhumbs are transformed in the ſtereographic projection of the ſphere on the plane of the equator: the doctrine of which was rendered ſtill more eaſy and elegant by the ingenious Mr. Cotes, in his Logometria, firſt printed in the Philoſ. Tranſ. for 1714, and afterwards in the collection of his works publiſhed 1732, by his couſin Dr. Robert Smith, who ſucceeded him as Plumian profeſſor of philoſophy in the Univerſity of Cambridge."

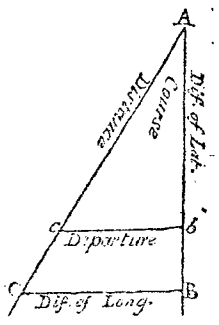
The learned Dr. Iſaac Barrow alſo, in his Lectiones Geometricæ, Lect. xi, Append. firſt publiſhed in 1672, delivers a ſimilar property, namely, "that the ſum of all the ſecants of any arc, is analogous to the logarithm of the ratio of $r + s$ to $r - s$, viz, radius plus ſine to radius minus ſine; or, which is the ſame thing, that the meridional parts anſwering to any degree of latitude, are as the logarithms of the ratios of the verſed ſines of the diſtances from the two poles." Preface to my Logarithms, pa. 100.

The meridian line in Mercator's Chart, is a ſcale of logarithmic tangents of the half colatitudes. The differences of longitude on any rhumb, are the logarithms of the ſame tangents, but of a different ſpecies; thoſe ſpecies being to each other, as the tangents of the angles made with the meridian. Hence any ſcale of logarithmic tangents is a table of the differences of longitude, to ſeveral latitudes, upon ſome one determinate rhumb; and therefore, as the tangent of the angle of ſuch a rhumb, is to the tangent of any other rhumb, ſo is the difference of the logarithms of any two tangents, to the difference of longitude on the propoſed rhumb, intercepted between the two latitudes, of whoſe half complements the logarithmic tangents were taken.

It was the great ſtudy of our predeceſſors to contrive ſuch a chart in plano, with ſtraight lines, on which all, or any parts of the world, might be truly ſet down, according to their longitudes and latitudes, bearings and diſtances. A method for this purpoſe was hinted by Ptolomy, near 2000 years ſince; and a general map, on ſuch an idea, was made by Mercator; but the principles were not demonſtrated, and a ready way ſhewn of deſcribing the chart, till Wright explained how to enlarge the meridian line by the continual addition of ſecants; ſo that all degrees of longitude might be proportional to thoſe of latitude, as on the globe: which renders this chart, in ſeveral reſpects, far more convenient for the navigator's uſe, than the globe itſelf; and which will truly ſhew the courſe and diſtance from place to place, in all caſes of ſailing.

MERCATOR'S *Sailing*, or more properly *Wright's* Sailing, is the method of computing the caſes of ſailing on the principles of Mercator's chart, which principles were laid down by Edward Wright in the beginning of the laſt century; or the art of finding on a plane the motion of a ſhip upon any aſſigned courſe, that ſhall be true as well in longitude and latitude, as diſtance; the meridians being all parallel, and the parallels of latitude ſtraight lines.

In the right-angled triangle A*bc*, let A*b* be the true difference of latitude between two places, the angle *b*A*c* the angle of the courſe ſailed, and A*c* the true diſtance ſailed; then will *bc* be what is called the departure, as in plane ſailing: produce A*b* till AB be equal to the meridional difference of latitude, and draw BC parallel to *bc*; ſo ſhall BC be the difference of longitude.



Now from the ſimilarity of the two triangles A*bc*, ABC, when three of the parts are given, the reſt may be found; as in the following analogies: As

Radius : ſin. courſe : : diſtance : departure;
Radius : cos. courſe : : diſtance : dif. lat.;
Radius : tan. courſe : : merid. dif. lat : dif. longitude.

And by means of theſe analogies may all the caſes of Mercator's Sailing be reſolved.

MERCURY, the ſmalleſt of the inferior planets, and the neareſt to the ſun, about which it is carried with a very rapid motion. Hence it was, that the Greeks called this planet after the name of the nimble meſſenger of the Gods, and repreſented it by the figure of a youth with wings at his head and feet; from whence is derived ☿, the character in preſent uſe for this planet.

The mean diſtance of Mercury from the ſun, is to that of the earth from the ſun, as 387 to 1000, and therefore his diſtance is about 36 millions of miles, or little more than one-third of the earth's diſtance from the

the ſun. Hence the ſun's diameter will appear at Mercury, near 3 times as large as at the earth; and hence alſo the ſun's light and heat received there is about 7 times thoſe at the earth; a degree of heat ſufficient to make water boil. Such a degree of heat therefore muſt render Mercury not habitable to creatures of our conſtitution: and if bodies on its ſurface be not inflamed, and ſet on fire, it muſt be becauſe their degree of denſity is proportionably greater than that of ſuch bodies is with us.

The diameter of Mercury is alſo nearly one-third of the diameter of the earth, or about 2600 miles. Hence the ſurface of Mercury is nearly 1-9th, and his magnitude or bulk 1-27th of that of the earth.

The inclination of his orbit to the plane of the ecliptic, is 6° 54′; his period of revolution round the ſun, 87days 23hours; his greateſt elongation from the ſun 28°; the excentricity of his orbit $\frac{1}{5}$ of his mean diſtance, which is far greater than that of any of the other planets; and he moves in his orbit about the ſun at the amazing rate of 95000 miles an hour.

The place of his aphelion is ♐ 23° 8′; place of aſcending node ♉ 14° 43′, and conſequently that of the deſcending node ♏ 14° 43′.

His Length of day, or rotation on his axis, Inclination of axis to his orbit, Gravity on his ſurface, Denſity, and Quantity of matter, are all unknown.

Mercury changes his phaſes, like the moon, according to his various poſitions with regard to the earth and ſun; except only, that he never appears quite full, becauſe his enlightened ſide is never turned directly towards us, unleſs when he is ſo near the ſun as to be loſt to our ſight in his beams. And as his enlightened ſide is always towards the ſun, it is plain that he ſhines not by any light of his own; for if he did, he would conſtantly appear round.

The beſt obſervations of this planet are thoſe made when it is ſeen on the ſun's diſc, called its tranſit; for in its lower conjunction, it ſometimes paſſes before the ſun like a little ſpot, eclipſing a ſmall part of the ſun's body, only obſervable with a teleſcope. That node from which Mercury aſcends northward above the ecliptic, is in the 15th degree of Taurus, and the oppoſite in the 15th degree of Scorpio. The earth is in thoſe parts on the 6th of November, and 4th of May, new ſtyle; and when Mercury comes to either of his nodes at his inferior conjunction about theſe times, he will appear in this manner to paſs over the diſc of the ſun. But in all other parts of his orbit, his conjunctions are inviſible, becauſe he goes either above or below the ſun. The firſt obſervation of this kind was made by Gaſſendi, in November 1631. Several following obſervations of the like tranſits are collected in Du Hamel's Hiſt. of the Royal Acad. of Sciences, pa. 470, ed. 2. And Mr. Whiſton has given a liſt of ſeveral periods at which Mercury may be ſeen on the ſun's diſc, viz, in 1782, Nov. 12, at 3h 44m afternoon; in 1786, May 4th, at 6h 57m in the forenoon; in 1789, Dec. 6th, at 3h 55m afternoon; and in 1799, May 7th, at 2h 34m afternoon. There are alſo ſeveral intermediate tranſits, but none of them viſible at London. See Dr. Halley's account of the Tranſits of Mercury and Venus, in the Philoſ. Tranſ. n°. 193.

MERIDIAN, in Aſtronomy, is a great circle of the celeſtial ſphere, paſſing through the poles of the world, and both the zenith and nadir, croſſing the equinoctial at right angles, and dividing the ſphere into two equal parts, or hemiſpheres, the one eaſtern, and the other weſtern. Or, the Meridian is a vertical circle paſſing through the poles of the world.

It is called Meridian, from the Latin *meridies*, midday or noon, becauſe when the ſun comes to the ſouth part of this circle, it is noon to all thoſe places ſituated under it.

MERIDIAN, in Geography, is a great circle paſſing through the poles of the earth, and any given place whoſe Meridian it is; and it lies exactly under, or in the plane of, the celeſtial Meridian.

Theſe Meridians are various, and change according to the longitude of places; ſo that their number may be ſaid to be infinite, for that all places from eaſt to weſt have their ſeveral Meridians. Farther, as the Meridian inveſts the whole earth, there are many places ſituated under the ſame Meridian. Alſo, as it is noon whenever the centre of the ſun is in the celeſtial Meridian; and as the Meridian of the earth is in the plane of the former; it follows, that it is noon at the ſame time, in all places ſituated under the ſame Meridian.

Firſt MERIDIAN, is that from which the reſt are counted, reckoning both eaſt and weſt; and is the beginning of longitude.

The fixing of the Firſt Meridian is a matter merely arbitrary; and hence different perſons, nations, and ages, have fixed it differently: from which circumſtance ſome confuſion has ariſen in geography. The rule among the Ancients was, to make it paſs through the place fartheſt to the weſt that was known. But the Moderns knowing that there is no ſuch place on the earth as can be eſteemed the moſt weſterly, the way of computing the longitudes of places from one fixed point is much laid aſide.

Ptolomy aſſumed the Meridian that paſſes through the fartheſt of the Canary Iſlands, as his firſt Meridian; that being the moſt weſtern place of the world then known. After him, as more countries were diſcovered in that quarter, the Firſt Meridian was remov farther off. The Arabian geographers choſe to the Firſt Meridian upon the utmoſt ſhore of the weſtern ocean. Some fixed it to the iſland of St. Nicholas near the Cape Verd; Hondius to the iſle of St. James; others to the iſland of Del Corvo, one of the Azores; becauſe on that iſland the magnetic needle at that time pointed directly north, without any variation: and it was not then known that the variation of the needle is itſelf ſubject to variation. The lateſt geographers, particularly the Dutch, have pitched on the Pike of Teneriffe; others on the Iſle of Palm, another of the Canaries; and laſtly, the French, by order of the king, on the iſland of Fero, another of the Canaries.

But, without much regard to any of theſe rules, geographers and map-makers often aſſume the Meridian of the place where they live, or the capital of their country, or its chief obſervatory, for a Firſt Meridian; and from thence reckon the longitudes of places, eaſt and weſt.

Aſtronomers, in their calculations, uſually chooſe

the Meridian of the place where their obſervations are made, for their Firſt Meridian; as Ptolomy at Alexandria; Tycho Brahe at Uranibourg; Riccioli at Bologna; Flamſteed at the Royal Obſervatory at Greenwich; and the French at the Obſervatory at Paris.

There is a ſuggeſtion in the Philoſ. Tranſ. that the Meridians vary in time. And it has been ſaid that this is rendered probable, from the old Meridian line in the church of St. Petronio at Bologna, which is ſaid to vary no leſs than 8 degrees from the true Meridian of the place at this time; and from the Meridian of Tycho at Uranibourg, which M. Picart obſerves, varies 18 minutes from the modern Meridian. If there be any thing of truth in this hint, Dr. Wallis ſays, the alteration muſt ariſe from a change of the terreſtrial poles (here on earth, of the earth's diurnal motion), not of their pointing to this or that of the fixed ſtars: for if the poles of the diurnal motion remain fixed to the ſame place on the earth, the Meridians, which paſs through theſe poles, muſt remain the ſame.

But the notion of the changes of the Meridian ſeems overthrown by an obſervation of M. Chazelles, of the French Academy of Sciences, who, when in Egypt, found that the four ſides of a pyramid, built 3000 years ago, ſtill looked very exactly to the four cardinal points. A poſition which cannot be conſidered as merely fortuitous.

MERIDIAN *of a Globe*, or *Sphere*, is the brazen circle, in which the globe hangs and turns.

It is divided into four 90's, or 360 degrees, beginning at the equinoctial: on it, each way, from the equinoctial, on the celeſtial globes, is counted the north and ſouth declination of the ſun, moon, or ſtars; and on the terreſtrial globe, the latitude of places, north and ſouth. There are two points on this circle called the poles; and a diameter, continued from thence through the centre of either globe, is called the axis of the earth, or heavens, on which it is ſuppoſed they turn round.

On the terreſtrial globes there are uſually drawn 36 Meridians, one through every 10th degree of the equator, or through every 10th degree of longitude.

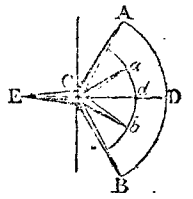
The uſes of this circle are, to ſet the globes in any particular latitude, to ſhew the ſun's or a ſtar's declination, right aſcenſion, greateſt altitude, &c.

MERIDIAN *Line*, an arch, or part, of the Meridian of the place, terminated each way by the horizon. Or, a Meridian line is the interſection of the plane of the Meridian of the place with the plane of the horizon, often called a north-and-ſouth line, becauſe its direction is from north to ſouth.

The Meridian line is of moſt eſſential uſe in aſtronomy, geography, dialling, &c; and the greateſt pains are taken by aſtronomers to fix it at their obſervatories to the utmoſt preciſion. M. Caſſini has diſtinguiſhed himſelf by a Meridian line drawn on the pavement of the church of St. Petronio, at Bologna; being extended to 120 feet in length. In the roof of this church, 1000 inches above the pavement, is a ſmall hole, through which the ſun's image, when in the meridian, falling upon the line, marks his progreſs all the year. When finiſhed, M. Caſſini, by a public writing, quaintly informed the mathematicians of Europe, of a new oracle of Apollo, or the ſun, eſtabliſhed in a temple, which might be conſulted, with entire confidence, as to all difficulties in aſtronomy. See GNOMON.

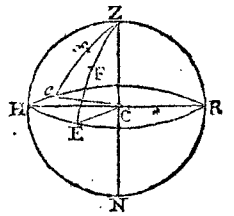
To draw a Meridian Line.—There are many ways of doing this; but ſome of the eaſieſt and ſimpleſt are as follow:

1. On an horizontal plane deſcribe ſeveral concentric circles AB, *ab*, &c, and on the common centre C erect a ſtile, or gnomon, perpendicular to the horizontal plane, of about a foot in length. About the 21ſt of June, between the hours of 9 and 11 in the morning, and between 1 and 3 in the afternoon, obſerve the points A, *a*, B, *b*, &c, in the circles, where the ſhadow of the ſtile terminates. Biſect the arches AB, *ab*, &c, in D, *d*, &c. If then the ſame right line DE biſect all theſe arches, it will be the Meridian line ſought.



As it is not eaſy to determine preciſely the extremity of the ſhadow, it will be beſt to make the ſtile flat at top, and to drill a ſmall hole through it, noting the lucid point projected by it on the arches AB and *ab*, inſtead of marking the extremity of the ſhadow itſelf.

2. Another method is thus: Knowing the ſouth quarter pretty nearly, obſerve the altitude FE of ſome ſtar on the eaſt ſide of it, and not far from the Meridian HZRN: then, keeping the quadrant firm on its axis, ſo as the plummet may ſtill cut the ſame degree, direct it to the weſtern ſide of the Meridian, and wait till you find the ſtar has the ſame altitude as before, as *fe*. Laſtly, biſect the angle EC*e*, formed by the interſection of the two planes in which the quadrant has been placed at the time of the two obſervations, by the right line HR, which will be the Meridian ſought.



Many other methods are given by authors, of deſcribing a Meridian line; as by the pole ſtar, or by equal altitudes of the ſun, &c; by Schooten in his Exercitationes Geometriæ; Grey, Derham, &c, in the Philoſ. Tranſ. and by Ferguſon in his Lectures on Select Subjects.

From what has been ſaid it is evident that whenever the ſhadow of the ſtile covers the Meridian line, the centre of the ſun is in the Meridian, and therefore it is then noon. And hence the uſe of a Meridian line in adjuſting the motion of clocks to the ſun.

If another ſtile be erected perpendicularly on any other horizontal plane, and a ſignal be given when the ſhadow of the former ſtile covers the Meridian line drawn on another plane, noting the apex or extremity of the ſhadow projected by the ſecond ſtile, a line drawn through that point and the foot of the ſtile will be a Meridian line at the 2d place.

Or, inſtead of the 2d ſtile, a plumb line may be hung up, and its ſhadow noted on a plane, upon a ſignal given that the ſhadow of another plummet, or

of

of a ſtile, falls exactly in another Meridian line, at a little diſtance; which ſhadow will give the other Meridian line parallel to the former.

MERIDIAN *Line*, on a Dial, is a right line ariſing from the interſection of the Meridian of the place with the plane of the dial. This is the line of noon, or 12 o'clock, and from hence the diviſion of the hour-line begins.

MERIDIAN *Line*, on Gunter's ſcale, is divided unequally towards 87 degrees, in ſuch manner as the Meridian in Mercator's chart is divided and numbered.

This line is very uſeful in navigation. For, 1ſt, It ſerves to graduate a ſea-chart according to the true projection. 2d, Being joined with a line of chords, it ſerves for the protraction and reſolution of ſuch rectilineal triangles as are concerned in latitude, longitude, courſe, and diſtance, in the practice of ſailing; as alſo in pricking the chart truly at ſea.

Magnetical MERIDIAN, is a great circle paſſing through or by the magnetical poles; to which Meridians the magnetical needle conforms itſelf.

Meridian Altitude, of the ſun or ſtars, is their altitude when in the meridian of the place where they are obſerved.

MERIDIONAL *Diſtance*, in Navigation, is the ſame with the Departure, or eaſting and weſting, or diſtance between two meridians.

MERIDIONAL *Parts*, *Miles*, or *Minutes*, in Navigation, are the parts of the increaſed or enlarged meridian, in the Mercator's chart. Tables of theſe parts are in moſt books of navigation; and they ſerve both for conſtructing that ſort of charts, and for working that kind of navigation.

Under the article MERCATOR's *Chart*, it is ſhewn that the parts of the enlarged Meridian increaſe in proportion as the coſine of the latitude to radius, or, which is the ſame thing, as radius to the ſecant of the latitude; and therefore it follows, that the whole length of the enlarged nautical Meridian, from the equator to any point, or latitude, will be proportional to the ſum of all the ſecants of the ſeveral latitudes up to that point of the Meridian. And on this principle was the firſt Table of Meridional Parts conſtructed, by the inventor of it, Mr. Edward Wright, and publiſhed in 1599; viz, he took the Meridional parts

of $1' =$ the ſec. of $1'$;
of $2' =$ ſec. of $1' +$ ſec. of $2'$;
of $3' =$ ſecants of 1, 2, and 3 min.
of $4' =$ ſecants of 1, 2, 3, and 4 min.

and ſo on by a conſtant addition of the ſecants.

The Tables of Meridional Parts, ſo conſtructed, are perhaps exact enough for ordinary practice in navigation; but they would be more accurate if the Meridian were divided into more or ſmaller parts than ſingle minutes; and the ſmaller the parts, ſo much the greater the accuracy. But, as a continual ſubdiviſion would greatly augment the labour of calculation, other ways of computing ſuch a table have been deviſed, and treated of, by Bond, Gregory, Oughtred, Sir Jonas Moor, Dr. Wallis, Dr. Halley, and others. See MERCATOR's *Chart*, and Robertſon's Navigation, vol. 2, book 8. The beſt of theſe methods was derived from this property, viz, that the Meridian line, in a Mercator's chart, is analogous to a ſcale of logarithmic tangents of half the complements of the latitudes; from which property alſo a method of computing the caſes of Mercator's Sailing has been deduced, by Dr. Halley. Vide ut ſupra, alſo the Philoſ. Tranſ. vol. 46, pa. 559.

To find the MERIDIONAL PARTS *to any Spheroid, with the ſame exactneſs as in a Sphere.*

Let the ſemidiameter of the equator be to the diſtance of the centre from the focus of the generating ellipſe, as m to 1. Let A repreſent the latitude for which the meridional parts are required, s the ſine of the latitude, to the radius 1: Find the arc B, whoſe ſine is $\frac{s}{m}$; take the logarithmic tangent of half the complement of B, from the common tables; ſubtract the log. tangent from 10·0000000, or the log. tangent of 45°; multiply the remainder by the number 7915·7044679, and divide the product by m; then the quotient ſubtracted from the Meridional parts in the ſphere, computed in the uſual manner for the latitude A, will give the Meridional parts, expreſſed in minutes, for the ſame latitude in the ſpheroid, when it is the oblate one.

Example. If $mm : 1 :: 1000 : 22$, then the greateſt difference of the Meridional parts in the ſphere and ſpheroid is 76·0929 minutes. In other caſes it is found by multiplying the remainder above mentioned by the number 1174·078.

When the ſpheroid is oblong, the difference in the Meridional parts between the ſphere and ſpheroid, for the ſame latitude, is then determined by a circular arc. See Philoſ. Tranſ. no. 461, ſect. 14. Alſo Maclaurin's Fluxions, art. 895, 899. And Murdoch's Mercator's Sailing &c.

MERLON, in Fortification, that part of the Parapet, which lies between two embraſures.

MERSENNE (MARTIN), a learned French author, was born at Bourg of Oyſe, in the province of Maine, 1588. He ſtudied at La Fleche at the ſame time with Des Cartes; with whom he contracted a ſtrict friendſhip, which continued till death. He afterwards went to Paris, and ſtudied at the Sorbonne; and in 1611 entered himſelf among the Minims. He became well ſkilled in Hebrew, philoſophy, and mathematics. From 1615 to 1619, he taught philoſophy and theology in the convent of Nevers; and became the Superior of that convent. But being deſirous of applying himſelf more freely and cloſely to ſtudy, he reſigned all the poſts he enjoyed in his order, and retired to Paris, where he ſpent the remainder of his life; excepting ſome ſhort excurſions which he occaſionally made into Italy, Germany, and the Netherlands.

Study and literary converſation were afterwards his whole employment. He held a correſpondence with moſt of the learned men of his time; being as it were the very centre of communication between literary men of all countries, by the mutual correſpondence which he managed between them; being in France what Mr. Collins was in England. He omitted no opportunity to engage them to publiſh their works; and the world is obliged to him for ſeveral excellent diſcoveries, which would probably have been loſt, but for his encouragement; and on all accounts he had the reputation of being one of the beſt men, as well as philoſophers,

of

of his time. No perſon was more curious in penetrating into the ſecrets of nature, and carrying all the arts and ſciences to perfection. He was the chief friend and literary agent of Des Cartes at Paris; giving him advice and aſſiſtance upon all occaſions, and informing him of all that paſſed at Paris and elſewhere. For, being a perſon of univerſal learning, but particularly excelling in phyſical and mathematical knowledge, Des Cartes ſcarcely ever did any thing, or at leaſt was not perfectly ſatisfied with any thing he had done, without firſt knowing what Merſenne thought of it. It is even ſaid, that when Merſenne gave out in Paris, that Des Cartes was erecting a new ſyſtem of phyſics upon the foundation of a vacuum, and found the public very indifferent to it on that very account, he immediately ſent notice to Des Cartes, that a vacuum was not then the faſhion at Paris; upon which, that philoſopher changed his ſyſtem, and adopted the old doctrine of a plenum.

Merſenne was a man of good invention alſo himſelf; and he had a peculiar talent in forming curious queſtions, though he did not always ſucceed in reſolving them; however, he at leaſt gave occaſion to others to do it. It is ſaid he invented the Cycloid, otherwiſe called the Roulette. Preſently the chief geometricians of the age engaged in the contemplation of this new curve, among whom Merſenne himſelf held a diſtinguiſhed rank. After a very ſtudious and uſeful life, he died at Paris in 1648, at 60 years of age.

Merſenne was author of many uſeful works, particularly the following:

1. *Queſtiones celeberrimæ in Geneſim.*
2. *Harmonicorum Libri.*
3. *De Sonorum Natura, Cauſis, et Effectibus.*
4. *Cogitata Phyſico-Mathematica*; 2 vols. 4to.
5. *La Verité des Sciences.*
6. *Les Queſtions inouies.*

Beſides many letters in the works of Des Cartes, and other authors.

MESOLABE, or MESOLABIUM, a mathematical inſtrument invented by the Ancients, for finding two mean proportionals mechanically, which they could not perform geometrically. It conſiſts of three parallelograms, moving in a groove to certain interſections. Its figure is deſcribed by Eutocius, in his Commentary on Archimedes. See alſo Pappus, lib. 3.

MESO-LOGARITHM, a term uſed by Kepler to ſignify the logarithms of the coſines and cotangents.

METO, or METON, the ſon of Pauſanias, a famous mathematician of Athens, who flouriſhed 432 years before Chriſt. In the firſt year of the 87th Olympiad, he obſerved the ſolſtice at Athens: and publiſhed his *Anneadecatoride*, that is, his *Cycle of* 19 *Years*; by which he endeavoured to adjuſt the courſe of the ſun to that of the moon, and to make the ſolar and lunar years begin at the ſame point of time. See CYCLE.

METONIC CYCLE, called alſo the *Golden Number*, and *Lunar Cycle*, or *Cycle of the Moon*, that which was invented by Meton the Athenian; being a period of 19 years. See CYCLE.

METOPE, or METOPA, in Architecture, the ſquare ſpace between the triglyphs of the Doric Freeze; which among the Ancients uſed to be adorned with the heads of beaſts, baſons, vaſes, and other inſtruments uſed in ſacrificing.

A *Demi-Metope* is a ſpace ſomewhat leſs than half a Metope, at the corner of the Doric Freeze.

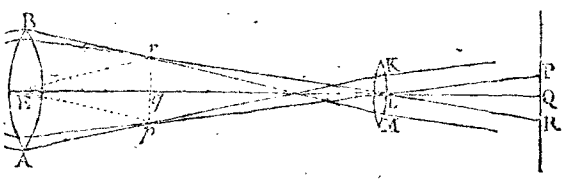
MICHAELMAS, the feaſt of St. Michael the archangel; held on the 29th of September.

MICROCOUSTICS, the ſame with MICROPHONES.

MICROMETER, is an inſtrument uſually fitted to a teleſcope, in the focus of the object-glaſs, for meaſuring ſmall angles or diſtances; as the apparent diameters of the planets, &c.

There are ſeveral ſorts of theſe inſtruments, upon different principles; the origin of which has been diſputed. The general principle is, that the inſtrument moves a fine wire parallel to itſelf, in the plane of the picture of an object, formed in the focus of a teleſcope, and ſo with great exactneſs to meaſure its perpendicular diſtance from a fixed wire in the ſame plane: and thus are meaſured ſmall angles, ſubtended by remote objects at the naked eye.

For example, Let a planet be viewed through the teleſcope; and when the parallel wires are opened to ſuch a diſtance as to appear exactly to touch two oppoſite points in the circumference of the planet, it is evident that the perpendicular diſtance between the wires is then equal to the diameter of the picture of the planet, formed in the focus of the object-glaſs. Let this diſtance, whoſe meaſure is given by the mechaniſm of the micrometer, be repreſented by the line



pq; then, ſince the meaſure of the focal diſtance *q*L may be alſo known, the ratio of *q*L to *qp*, that is, of radius to the tangent of the angle *q*L*p*, will give the angle itſelf, by a table of ſines and tangents; and this angle is equal to the oppoſite angle PLQ, which the real diameter of the planet ſubtends at L, or at the naked eye.

With reſpect to the invention of the Micrometer; Meſſ. Azout and Picard have the credit of it in common fame, as being the firſt who publiſhed it, in the year 1666; but Mr. Townley, in the Philoſ. Tranſ. reclaims it for one of our own countrymen, Mr. Gaſcoigne. He relates that, from ſome ſcattered papers and letters of this gentleman, he had learnt that before our civil wars he had invented a Micrometer, of as much effect as that ſince made by M. Azout, and had made uſe of it for ſome years, not only in taking the diameters of the planets, and diſtances upon land, but in determining other matters of nice importance in the heavens; as the moon's diſtance, &c. Mr. Gaſcoigne's inſtrument alſo fell into the hands of Mr. Townley, who ſays farther, that by the help of it he could make above 40,000 diviſions in a foot. This inſtrument being ſhewn to Dr. Hook, he gave a drawing and deſcription of it, and propoſed ſeveral improvements in it; which may be ſeen in the Philoſ. Tranſ. vol. 1, pa. 63, and Abr. vol. 1, pa. 217. Mr. Gaſcoigne divided the image of an object, in the focus of the object-glaſs, by the approach of two

two pieces of metal, ground to a very fine edge; inſtead of which, Dr. Hook would ſubſtitute two fine hairs, ſtretched parallel to each other: and two other methods of Dr. Hook, different from this, are deſcribed in his poſthumous works, pa. 497 &c. An account of ſeveral curious obſervations which Mr. Gaſcoigne made by the help of his Micrometer, particularly in meaſuring the diameter of the moon and other planets, may be ſeen in the Philoſ. Tranſ. vol. 48, pa. 190; where Dr. Bevis refers to an original letter of Mr. Gaſcoigne, to Mr. Oughtred, written in 1641, for an account given by the author of his own invention, &c.

Monſ. De la Hire, in a diſcourſe on the æra of the inventions of the Micrometer, pendulum clock, and teleſcope, read before the Royal Academy of Sciences in 1717, makes M. Huygens the inventor of the Micrometer. That author, he obſerves, in his Obſervations on Saturn's Ring, &c, publiſhed in 1659, gives a method of finding the diameters of the planets by means of a teleſcope, viz, by putting an object, which he calls a virgula, of a ſize proper to take in the diſtance to be meaſured, in the focus of the convex object-glaſs: in this caſe, ſays he, the ſmalleſt object will be ſeen very diſtinctly in that place of the glaſs. By ſuch means, he adds, he meaſured the diameter of the planets, as he there delivers them. See Huygens's Syſtem of Saturn.

This Micrometer, M. De la Hire obſerves, is ſo very little different from that publiſhed by the marquis De Malvaſia, in his Ephemerides, three years after, that they ought to be eſteemed the ſame: and the Micrometer of the marquis differed yet leſs from that publiſhed four years after his, by Azout and Picard. Hence, De la Hire concludes, that it is to Huygens the world is indebted for the invention of the Micrometer; without taking any notice of the claim of our countryman Gaſcoigne, which however is many years prior to any of them.

De la Hire ſays, that there is no method more ſimple or commodious for obſerving the digits of an eclipſe, than a net in the focus of the teleſcope. Theſe, he ſays, were uſually made of ſilken threads; and for this particular purpoſe ſix concentric circles had alſo been uſed, drawn upon oiled paper; but he adviſes to draw the circles on very thin pieces of glaſs, with the point of a diamond. He alſo gives ſome particular directions to aſſiſt perſons in uſing them. In another memoir, he ſhews a method of making uſe of the ſame net for all eclipſes, by uſing a teleſcope with two object-glaſſes, and placing them at different diſtances from each other. Mem. 1701 and 1717.

M. Caſſini invented a very ingenious method of aſcertaining the right aſcenſions and declinations of ſtars, by fixing four croſs hairs in the focus of the teleſcope, and turning it about its axis, ſo as to make them move in a line parallel to one of them. But the later improved Micrometers will anſwer this purpoſe with greater exactneſs. Dr. Maſkelyne has publiſhed directions for the uſe of it, extracted from Dr. Bradley's papers, in the Philoſ. Tranſ. vol. 62. See alſo Smith's Optics, vol. 2, pa. 343.

Wolfius deſcribes a Micrometer of a very eaſy and ſimple ſtructure, firſt contrived by Kirchius.

Dr. Derham tells us, that his Micrometer is not put into a tube, as is uſual, but is contrived to meaſure the ſpectres of the ſun on paper, of any radius, or to meaſure any part of them. By this means he can eaſily, and very exactly, with the help of a fine thread, take the declination of a ſolar ſpot at any time of the day; and, by his half-ſeconds watch, meaſure the diſtance of the ſpot from either limb of the ſun.

J. And. Segner propoſed to enlarge the field of view in theſe Micrometers, by making them of a conſiderable extent, and having a moveable eye-glaſs, or ſeveral eye-glaſſes, placed oppoſite to different parts of it. He thought however, that two would be quite ſufficient, and he gives particular directions how to make uſe of ſuch Micrometers in aſtronomical obſervations. See Comm. Gotting. vol. 1, pa. 27.

A conſiderable improvement in the Micrometer was communicated to the Royal Society, in 1743, by Mr. S. Savary; an account of which, extracted from the minutes by Mr. Short, was publiſhed in the Philoſ. Tranſ. for 1753. The firſt hint of ſuch a Micrometer was ſuggeſted by M. Roemer, in 1675: and M. Bouguer propoſed a conſtruction ſimilar to that of M. Savary, in 1748; for which ſee HELIOMETER. The late Mr. Dollond made a farther improvement in this kind of Micrometer, an account of which was given to the Royal Society by Mr. Short, and publiſhed in the Philoſ. Tranſ. vol. 48. Inſtead of two object-glaſſes, he uſed only one, which he neatly cut into two ſemicircles, and fitted each ſemicircle in a metal frame, ſo that their diameters ſliding in one another, by means of a ſcrew, may have their centres ſo brought together as to appear like one glaſs, and ſo form one image; or by their centres receding, may form two images of the ſame object: it being a property of ſuch glaſſes, for any ſegment to exhibit a perfect image of an object, although not ſo bright as the whole glaſs would give it. If proper ſcales are fitted to this inſtrument, ſhewing how far the centres recede, relative to the focal length of the glaſs, they will alſo ſhew how far the two parts of the ſame object are aſunder, relative to its diſtance from the object-glaſs; and conſequently give the angle under which the diſtance of the parts of that object are ſeen. This divided object-glaſs Micrometer, which was applied by the late Mr. Dollond to the object end of a reflecting teleſcope, and has been with equal advantage adapted by his ſon to the end of an achromatic teleſcope, is of ſo eaſy uſe, and affords ſo large a ſcale, that it is generally looked upon by aſtronomers as the moſt convenient and exact inſtrument for meaſuring ſmall diſtances in the heavens. However, the common Micrometer is peculiarly adapted for meaſuring differences of right aſcenſion, and declination, of celeſtial objects, but leſs convenient and exact for meaſuring their abſolute diſtances; whereas the object-glaſs Micrometer is peculiarly fitted for meaſuring diſtances, though generally ſuppoſed improper for the former purpoſe. But Dr. Maſkelyne has found that this may be applied with very little trouble to that purpoſe alſo; and he has furniſhed the directions neceſſary to be followed when it is uſed in this manner. The addition requiſite for this purpoſe, is a cell, containing two wires, interſecting each other at right angles, placed in the focus of the eye-glaſs of the teleſcope, and moveable round about, by the turning of a button. For the deſcription of this apparatus, with the method of applying and uſing

it,

it, ſee Dr. Maſkelyne's paper on the ſubject, in the Philoſ. Tranſ. vol. 61, pa. 536 &c.

After all, the uſe of the object-glaſs Micrometer is attended with difficulties, ariſing from the alterations in the focus of the eye, which are apt to cauſe it to give different meaſures of the ſame angle at different times. To obviate theſe difficulties, Dr. Maſkelyne, in 1776, contrived a priſmatic Micrometer, or a Micrometer conſiſting of two achromatic priſms, or wedges, applied between the object-glaſs and eye-glaſs of an achromatic teleſcope, by moving of which wedges nearer to or farther from the object-glaſs, the two images of an object produced by them appeared to approach to, or recede from, each other, ſo that the focal length of the object-glaſs becomes a ſcale for meaſuring the angular diſtance of the two images. The rationale and uſe of this Micrometer are explained in the Philoſ. Tranſ. vol. 67, pa. 799, &c. And a ſimilar invention by the abbé Rochon, and improved by the abbé Boſcovich, was alſo communicated to the Royal Society, and publiſhed in the ſame volume of the Tranſactions, pa. 789 &c.

Mr. Ramſden has lately deſcribed two new Micrometers, which he has contrived for remedying the defects of the object-glaſs Micrometer. One of theſe is a catoptric Micrometer, which, beſides the advantage it derives from the principle of reflection, of not being diſturbed by the heterogeneity of light, avoids every defect of other Micrometers, and can have no aberration, nor any defect ariſing from the imperfection of materials, or of execution; as the great ſimplicity of its conſtruction requires no additional mirrors or glaſſes, to thoſe required for the teleſcope; and the ſeparation of the image being effected by the inclination of the two ſpecula, and not depending on the focus of lens or mirror, any alteration in the eye of an obſerver cannot affect the angle meaſured. It has peculiar to itſelf the advantages of an adjuſtment, to make the images coincide in a direction perpendicular to that of their motion; and alſo of meaſuring the diameter of a planet on both ſides of the zero; which will appear no inconſiderable advantage to obſervers who know how much eaſier it is to aſcertain the contact of the external edges of two images than their perfect coincidence.

The other Micrometer invented and deſcribed by Mr. Ramſden, is ſuited to the principle of refraction. This Micrometer is applied to the erect eye-tube of a refracting teleſcope, and is placed in the conjugate focus of the firſt eye-glaſs, as the image is conſiderably magnified before it comes to the Micrometer, any imperfection in its glaſs will be magnified only by the remaining eye-glaſſes, which in any teleſcope ſeldom exceeds 5 or 6 times; and beſides, the ſize of the Micrometer glaſs will not be the 100th part of the area which would be required, if it were placed at the object-glaſs; and yet the ſame extent of ſcale is preſerved, and the images are uniformly bright in every part of the field of the teleſcope. See the deſcription and conſtruction of theſe two Micrometers in the Philoſ. Tranſ. vol. 69, part 2, art. 27.

In vol. 72 of the Philoſ. Tranſ. for the year 1782, Dr. Herſchel, after explaining the defects and imperfections of the parallel-wire Micrometer, eſpecially for meaſuring the apparent diameter of ſtars, and the diſtances between double and multiple ſtars, deſcribes one, for theſe purpoſes, which he calls a lamp Micrometer; one that is free from ſuch defects, and has the advantage of a very enlarged ſcale. In ſpeaking of the application of this inſtrument, he ſays, "It is well known to opticians and others, who have been in the habit of uſing optical inſtruments, that we can with one eye look into a microſcope or teleſcope, and ſee an object much magnified, while the naked eye may ſee a ſcale upon which the magnified picture is thrown. In this manner I have generally determined the power of my teleſcopes; and any one who has acquired a facility of taking ſuch obſervations, will very ſeldom miſtake ſo much as one in 50 in determining the power of an inſtrument, and that degree of exactneſs is fully ſufficient for the purpoſe.

"The Newtonian form is admirably adapted to the uſe of this Micrometer; for the obſerver ſtands always erect, and looks in a horizontal direction, notwithſtanding the teleſcope ſhould be elevated to the zenith.—The ſcale of the Micrometer at the convenient diſtance of 10 feet from the eye, with the power of 460, is above a quarter of an inch to a ſecond; and by putting on my power of 932, I obtain a ſcale of more than half an inch to a ſecond, without increaſing the diſtance of the Micrometer; whereas the moſt perfect of my former Micrometers, with the ſame inſtrument, had a ſcale of leſs than the 2000th part of an inch to a ſecond.

"The meaſures of this Micrometer are not confined to double ſtars only, but may be applied to any other objects that require the utmoſt accuracy, ſuch as the diameters of the planets or their ſatellites, the mountains of the moon, the diameters of the fixed ſtars, &c."

The Micrometer has not only been applied to teleſcopes, and employed for aſtronomical purpoſes; but there have been various contrivances for adapting it to microſcopical obſervations. Mr. Leeuwenhoek's method of eſtimating the ſize of ſmall objects, was by comparing them with grains of ſand, of which 100 in a line took up an inch. Theſe grains he laid upon the ſame plate with his objects, and viewed them at the ſame time. Dr. Jurin's method was ſimilar to this; for he found the diameter of a piece of fine ſilver wire, by wrapping it very cloſe upon a pin, and obſerving how many rings made an inch: and he uſed this wire in the ſame manner as Leeuwenhoek uſed his ſand. Dr. Hook uſed to look upon the magnified object with one eye, while at the ſame time he viewed other objects, placed at the ſame diſtance, with the other eye. In this manner he was able, by the help of a ruler, divided into inches and ſmall parts, and laid on the pedeſtal of the microſcope, as it were to caſt the magnified appearance of the object upon the ruler, and thus exactly to meaſure the diameter which it appeared to have through the glaſs; which being compared with the diameter as it appeared to the naked eye, eaſily ſhewed the degree in which it was magnified. A little practice, ſays Mr. Baker, will render this method exceedingly eaſy and pleaſant.

Mr. Martin, in his Optics, recommends ſuch a Micrometer for a microſcope as had been applied to teleſcopes; for he adviſes to draw a number of parallel lines on a piece of glaſs, with the fine point of a diamond, at the diſtance of one 40th of an inch from one another, and to place it in the focus of the eye-glaſs.

By this method, Dr. Smith contrived to take the exact draught of objects viewed by a double microscope; for he advises to get a lattice, made with small silver wires or squares, drawn upon a plain glass by the strokes of a diamond, and to put it into the place of the image formed by the object-glass. Then, by transferring the parts of the object, seen in the squares of the glass or lattice, upon similar corresponding squares drawn on paper, the picture may be exactly taken. Mr. Martin also introduced into compound microscopes another Micrometer, consisting of a screw. See both these methods described in his Optics, pa. 277.

A very accurate division of a scale is performed by Mr. Coventry, of Southwark. The Micrometers of his construction are parallel lines drawn on glass, ivory, or metal, from the 10th to the 10,000th part of an inch. These may be applied to microscopes, for measuring the size of minute objects, and the magnifying power of the glasses; and to telescopes, for measuring the size and distance of objects, and the magnifying power of the instrument. To measure the size of an object in a single microscope; lay it on a Micrometer, whose lines are seen magnified in the same proportion with it, and they give at one view the real size of the object. For measuring the magnifying power of the compound microscope, the best and readiest method is the following: On the stage in the focus of the object-glass, lay a Micrometer, consisting of an inch divided into 100 equal parts; count how many divisions of the Micrometer are taken into the field of view; then lay a two-foot rule parallel to the Micrometer: fix one eye on the edge of the field of light, and the other eye on the end of the rule, which move, till the edge of the field of light and the end of the rule correspond; then the distance from the end of the rule to the middle of the stage, will be half the diameter of the field: ex. gr. If the distance be 10 inches, the whole diameter will be 20, and the number of the divisions of the Micrometer contained in the diameter of the field, is the magnifying power of the microscope. For measuring the height and distance of objects by a Micrometer in the telescope, see TELESCOPE.

Mr. Adams has applied a Micrometer, that instantly shews the magnifying power of any telescope.

In the Philos. Trans. for 1791, a very simple scale Micrometer for measuring small angles with the telescope is described by Mr. Cavallo. This Micrometer consists of a thin and narrow slip of mother-of-pearl finely divided, and placed in the focus of the eye-glass of a telescope, just where the image of the object is formed; whether the telescope is a reflector or a refractor, provided the eye-glass be a convex lens. This substance Mr. Cavallo, after many trials, found much more convenient than either glass, ivory, horn, or wood, as it is a very steady substance, the divisions very easy marked upon it, and when made as thin as common writing paper it has a very useful degree of transparency.

Upon this subject, see M. Azout's Tract on it, contained in *Divers Ouvrages de Mathematique & de Physique; par Messieurs de l'Academie Royal des Sciences; M. de la Hire's Astronomicæ Tabulæ*; Mr. *Townley*, in the *Philos. Trans.* n°. 21; *Wolfius*, in his *Elem. Astron.* § 508; Dr. *Hook*, and many others, in the *Philos. Trans.* n°. 29 &c; *Hevelius*, in the *Acta Eruditorum, ann.* 1708; Mr. *Balsbaser*, in his *Micrometria*; also several volumes of the *Paris Memoirs*, &c.

MICROPHONES, instruments contrived to magnify small sounds, as microscopes do small objects.

MICROSCOPE, an optical instrument, composed of lenses or mirrors, by means of which small objects are made to appear larger than they do to the naked eye.

MICROSCOPES are distinguished into simple and compound, or single and double.

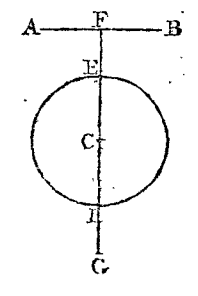
Simple, or *Single* MICROSCOPES, are such as consist of a single lens, or a single spherule. And a

Compound MICROSCOPE consists of several lenses duly combined.—As optics have been improved, other varieties have been contrived in this instrument: Hence reflecting Microscopes, water Microscopes, &c.

It is not certainly known when, or by whom, Microscopes were first invented; although it is probable they would soon follow upon the use of telescopes, since a Microscope is like a telescope inverted. We are informed by Huygens, that one Drebell, a Dutchman, had the first Microscope, in the year 1621, and that he was reputed the inventor of it: though F. Fontana, a Neapolitan, in 1646, claims the invention to himself, and dates it from the year 1618. Be this as it may, it seems they were first used in Germany about 1621. According to Borelli, they were invented by Zacharias Janssen and his son, who presented the first Microscopes they had constructed to prince Maurice, and Albert arch-duke of Austria. William Borelli, who gives this account in a letter to his brother Peter, says, that when he was ambassador in England, in 1619, Cornelius Drebell shewed him a Microscope, which he said was the same that the arch-duke had given him, and had been made by Janssen himself. Borelli De vero Telescopii inventore, pa. 35. See LENS.

Theory and *Foundation* of MICROSCOPES.

If an object be placed in the focus of the convex lens of a single Microscope, and the eye be very near on the other side, the object will appear distinct in an erect situation, and magnified in the ratio of the focal distance of the lens, to the ordinary distance of distinct vision, viz, about 8 inches.



So, if the object AB be placed in the focus F, of a small glass sphere, and the eye behind it, as in the focus G, the object will appear distinct, and in an erect posture, increased as to diameter in the ratio of $\frac{3}{4}$ of the diameter EI to 8 inches. If, ex. gr. the diameter EI of the small sphere be $\frac{1}{10}$ of an inch; then $CE = \frac{1}{20}$, and $FE = \frac{1}{4}CE = \frac{1}{80}$, so that $CF = \frac{3}{80}$; then as $\frac{3}{80} : 8$, or as $3 : 320$, or as $1 : 106\frac{2}{3}$ :: the natural size to the magnified appearance; that is, the object is magnified about 107 times.

Hence the smaller the spherule or the lens is, so much the more is the object magnified. But then, so much

much the leſs part is comprehended at one view, and ſo much the leſs diſtinct is the appearance of the object.

Equal appearances of the ſame object, formed by different combinations, become obſcure in proportion as the number of rays conſtituting each pencil decreaſes, that is, in proportion to the ſmallneſs of the object-glaſs.

Wherefore, if the diameter of the object-glaſs exceeds the diameter of the pupil, as many times as the diameter of the appearance exceeds the diameter of the object; the appearance ſhall be as clear and bright as the object itſelf.

The diameter of the object-glaſs cannot be ſo much increaſed, without increaſing at the ſame time the focal diſtances of all the glaſſes, and conſequently the length of the inſtrument: Otherwiſe the rays would fall too obliquely upon the eye-glaſs, and the appearance become confuſed and irregular.

There are ſeveral kinds of ſingle Microſcopes; of which the following is the moſt ſimple.

AB (Plate xviii, fig. 1) is a little tube, to one end of which EC, is fitted a plain glaſs; to which any object, as a gnat, the wing of an inſect, or the like, is applied; to the other end AD, at a proper diſtance from the object, is applied a lens, convex on both ſides, of about an inch in diameter: the plane glaſs is turned to the ſun, or the light of a candle, and the object is ſeen magnified. And if the tube be made to draw out, lenſes or ſegments of different ſpheres may be uſed.

Again, a lens, convex on both ſides, is incloſed in a cell AC (fig. 2), and held there by the ſcrew H. Through the ſtem or pedeſtal CD paſſes a long ſcrew EF, carrying a ſtile or needle EG. In E is a ſmall tube; on which, and on the point G, the various objects are to be diſpoſed. Thus, lenſes of various ſpheres may be applied.

A good ſimple inſtrument of this kind is Mr. Wilſon's pocket Microſcope, which has 9 different magnifying glaſſes, 8 of which may be uſed with two different inſtruments, for the better applying them to various objects. One of theſe inſtruments is repreſented at AABB (fig. 3), which is made either of braſs or ivory. There are three thin braſs plates at E, and a ſpiral ſpring H of ſteel wire within it: to one of the thin plates of braſs is fixed a piece of leather F, with a ſmall furrow G, both in the leather, and braſs to which it is fixed: in one end of this inſtrument there is a long ſcrew D, with a convex glaſs C, placed in the end of it: in the other end of the inſtrument there is a hollow ſcrew *oo*, in which any of the magnifying glaſſes, M, are ſcrewed, when they are to be made uſe of. The 9 different magnifying glaſſes are all ſet in ivory, 8 of which are ſet in the manner expreſſed at M. The greateſt magnifier is marked upon the ivory, in which it is ſet, number 1, the next number 2, and ſo on to number 8; the 9th glaſs is not marked, but is ſet in the manner of a little barrel box of ivory, as at *b*. At *ee* is a flat piece of ivory, of which there are 8 belonging to this ſort of Microſcopes (though any one who has a mind to keep a regiſter of objects may have as many of them as he pleaſes); in each of them there are 3 holes *fff*, in which 3 or more objects are placed between two thin glaſſes, or talcs, when they are to be uſed with the greater magnifiers.

The uſe of this inſtrument AABB is this. A handle W, from fig. 4, being ſcrewed upon the button S, take one of the flat pieces of ivory or ſliders *ee*, and ſlide it between the two thin plates of braſs at E, through the body of the Microſcope, ſo that the object to be viewed be juſt in the middle; remarking to put that ſide of the plate *ee*, where the braſs rings are, fartheſt from the end AA: then ſcrew into the hollow ſcrew, *oo*, the 3d, 4th, 5th, 6th, or 7th magnifying glaſs M; which being done, put the end AA cloſe to your eye, and while looking at the object through the magnifying glaſs, ſcrew in or out the long ſcrew D, which moving round upon the leather F, held tight to it by the ſpiral wire H, will bring your object to the true diſtance; which may be known by ſeeing it clearly and diſtinctly.

Thus may be viewed all tranſparent objects, duſts, liquids, cryſtals of ſalts, ſmall inſects, ſuch as fleas, mites, &c. If they be inſects that will creep away, or ſuch objects as are to be kept, they may be placed between the two regiſter glaſſes *ff*. For, by taking out the ring that keeps in the glaſſes *ff*, where the object lies, they will fall out of themſelves; ſo the object may be laid between the two hollow ſides of them, and the ring put in again as before; but if the objects be duſts or liquids, a ſmall drop of the liquid, or a little of the duſt laid on the outſide of the glaſs *ff*, and applied as before, will be ſeen very eaſily.

As to the 1ſt, 2d, and 3d magnifying glaſſes, being marked with a + upon the ivory in which they are ſet, they are only to be uſed with thoſe plates or ſliders that are alſo marked with a +, in which the objects are placed between two thin talcs; becauſe the thickneſs of the glaſſes in the other plates or ſliders, hinders the object from approaching to the true diſtance from theſe greater magnifiers. But the manner of uſing them is the ſame with the former.

For viewing the circulation of the blood at the extremities of the arteries and veins, in the tranſparent parts of fiſhes tails, &c, there are two glaſs tubes, a larger and a ſmaller, as expreſſed at *gg*, into which the animal is put. When theſe tubes are to be uſed, unſcrew the end ſcrew D in the body of the Microſcope, until the tube *gg* can be eaſily received into that little cavity G of the braſs plate faſtened to the leather F under the other two thin plates of braſs at E. When the tail of the fiſh lies flat on the glaſs tube, ſet it oppoſite to the magnifying glaſs, and bringing it to the proper diſtance by ſcrewing in or out the end ſcrew D, when the blood will be ſeen clearly circulating.

To view the blood circulating in the foot of a frog; chooſe ſuch a frog as will juſt go into the tube; then with a little ſtick expand its hinder foot, which apply cloſe to the ſide of the tube, obſerving that no part of the frog hinders the light from coming on its foot; and when it is brought to the proper diſtance, by means of the ſcrew D, the rapid motion of the blood will be ſeen in its veſſels, which are very numerous, in the tranſparent thin membrane or web between the toes. For this object, the 4th and 5th magnifiers will do very well;

well; but the circulation may be ſeen in the tails of water-newts in the 6th and 7th glaſſes, becauſe the globules of the blood of thoſe newts are as large again as the globules of the blood of frogs or ſmall fiſh, as has been remarked in number 280 of the Philoſ. Tranſ. pa. 1184.

The circulation cannot ſo well be ſeen by the 1ſt, 2d, and 3d magnifiers, becauſe the thickneſs of the glaſs tube, containing the fiſh, hinders the approach of the object to the focus of the magnifying glaſs. Fig. 4 is another inſtrument for this purpoſe.

In viewing objects, one ought to be careful not to hinder the light from falling upon them by the hat, hair, or any other thing, eſpecially in looking at opaque objects; for nothing can be ſeen with the beſt of glaſſes, unleſs the object be at a due diſtance, with a ſufficient light. The beſt lights for the plates or ſliders, when the object lies between the two glaſſes, is a clear ſky-light, or where the ſun ſhines on ſomething white, or the reflection of the light from a looking-glaſs. The light of a candle is alſo good for viewing very ſmall objects, though it be a little uneaſy to thoſe who are not practiſed in the uſe of Microſcopes.

To caſt ſmall Glaſs Spherules for MICROSCOPES.— There are ſeveral methods for this purpoſe. Hartſoeker firſt improved ſingle Microſcopes by uſing ſmall globules of glaſs, melted in the flame of a candle; by which he diſcovered the animalculæ in ſemine maſculino, and thereby laid the foundation of a new ſyſtem of generation. Wolfius deſcribes the following method of making ſuch globules: A ſmall piece of very fine glaſs, ſticking to the wet point of a ſteel needle, is to be applied to the extreme bluiſh part of the flame of a lamp, or rather of ſpirits of wine, which will not black it; being there melted, and run into a ſmall round drop, it is to be removed from the flame, on which it inſtantly ceaſes to be fluid. Then folding a thin plate of braſs, and making very ſmall ſmooth perforations, ſo as not to leave any roughneſs on the ſurfaces, and alſo ſmoothing them over to prevent any glaring, fit the ſpherule between the plates againſt the apertures, and put the whole in a frame, with objects convenient for obſervation.

Mr. Adams gives another method, thus: Take a piece of fine window-glaſs, and raſe it, with a diamond, into as many lengths as you think needful, not more than 1-8th of an inch in breadth; then holding one of thoſe lengths between the fore finger and thumb of each hand, over a very fine flame, till the glaſs begins to ſoften, draw it out till it be as fine as a hair, and break; then applying each of the ends into the pureſt part of the flame, you preſently have two ſpheres, which may be made greater or leſs at pleaſure: if they remain long in the flame, they will have ſpots; ſo they muſt be drawn out immediately after they are turned round. Break the ſtem off as near the globule as poſſible; and, lodging the remainder of the ſtem between the plates, by drilling the hole exactly round, all the protuberances are buried between the plates; and the Microſcope performs to admiration.

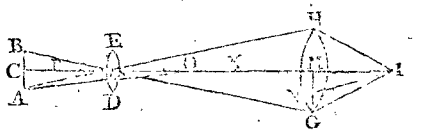
Mr. Butterfield gave another manner of making theſe globules, in number 141 Philoſ. Tranſ.

In any of theſe ways may the ſpherules be made much ſmaller than any lens; ſo that the beſt ſingle Microſcopes, or ſuch as magnify the moſt, are made of them. Leeuwenhoeck and Muſſchenbroek have ſucceeded very well in ſpherical Microſcopes, and their greateſt magnifiers enlarged the diameter of an object about 160 times; Philoſ. Tranſ. vol. 7, pa. 129, and vol. 8, pa. 121. But the ſmalleſt globules, and conſequently the higheſt magnifiers for Microſcopes, were made by F. de Torre of Naples, who, in 1765, ſent four of them to the Royal Society. The largeſt of them was only two Paris points in diameter, and magnified a line 640 times; the ſecond was the ſize of one Paris point, and magnified 1280 times; and the 3d no more than half a Paris point, or the 144th part of an inch in diameter, and magnified 2560 times. But ſince the focus of a glaſs globule is at the diſtance of one-4th of its diameter, and therefore that of the 3d globule of de Torre, above mentioned, only the 576th part of an inch diſtant from the object, it muſt be with the utmoſt difficulty that globules ſo minute as thoſe can be employed to any purpoſe; and Mr. Baker, to whoſe examination they were referred, conſiders them as matters of curioſity rather than of real uſe. Philoſ. Tranſ. vol. 55, pa. 246, vol. 56, pa. 67.

Water MICROSCOPE. Mr. S. Gray, and, after him, Wolfius and others, have contrived water Microſcopes, conſiſting of ſpherules or lenſes of water, inſtead of glaſs. But ſince the diſtance of the focus of a lens or ſphere of water is greater than that in one of glaſs, the ſpheres of which they are ſegments being the ſame, conſequently water Microſcopes magnify leſs than thoſe of glaſs, and therefore are leſs eſteemed. Mr. Gray firſt obſerved, that a ſmall drop or ſpherule of water, held to the eye by candle light or moon light, without any other apparatus, magnified the animalcules contained in it, vaſtly more than any other Microſcope. The reaſon is, that the rays coming from the interior ſurface of the firſt hemiſphere, are reflected ſo as to fall under the ſame angle on the ſurface of the hinder hemiſphere, to which the eye is applied, as if they came from the focus of the ſpherule; whence they are propagated to the eye in the ſame manner as if the objects were placed without the ſpherule in its focus.

Hollow glaſs ſpheres of about half an inch diameter, filled with ſpirit of wine, are often uſed for Microſcopes; but they do not magnify near ſo much.

Theory of Compound or Double MICROSCOPES.— Suppoſe an object-glaſs ED, the ſegment of a very ſmall



ſphere, and the object AB placed without the focus F. Suppoſe an eye-glaſs GH, convex on both ſides, and the ſegment of a ſphere greater than that of DE, though not too great; and, the focus being at K, let it be ſo diſpoſed behind the object,

that CF : CL :: CL : CK.

Laſtly ſuppoſe LK : LM :: LM : LI.

If then O be the place where an object is ſeen diſtinct with the naked eye; the eye in this caſe, being placed in I, will ſee the object AB diſtinctly, in an inverted poſition, and magnified in the compound ratio of MK × LC to LK × CO; as is proved by the laws of dioptrics; that is, the image is larger than the object, and we are able to view it diſtinctly at a leſs diſtance. For Examp.—If the image be 20 times larger than the object, and by the help of the eye-glaſs we are able to view it 5 times nearer than we could have done with the naked eye, it will, on both theſe accounts, be magnified 5 times 20, or 100 times.

Laws of Double MICROSCOPES.

1. The more an object is magnified by the Microſcope, the leſs is its field, i. e. the leſs of it is taken in at one view.

2. To the ſame eye-glaſs may be ſucceſſively applied object-glaſſes of various ſpheres, ſo as that both the entire objects, but leſs magnified, and their ſeveral parts, much more magnified, may be viewed through the ſame Microſcope. In which caſe, on account of the different diſtance of the image, the tube in which the lenſes are fitted, ſhould be made to draw out.

3. Since it is proved, that the diſtance of the image LK, from the object-glaſs DE, will be greater, if another lens, concave on both ſides, be placed before its focus; it follows, that the object will be magnified the more, if ſuch a lens be here placed between the object-glaſs DE, and the eye-glaſs GH. Such a Microſcope is much commended by Conradi, who uſed an object-lens, convex on both ſides, whoſe radius was 2 digits, its aperture equal to a muſtard ſeed; a lens, concave on both ſides, from 12 to 16 digits; and an eye-glaſs, convex on both ſides, of 6 digits.

4. Since the image is projected to the greater diſtance, the nearer another lens, of a ſegment of a larger ſphere, is brought to the object-glaſs; a Microſcope may be compoſed of three lenſes, which will magnify prodigiouſly.

5. From theſe conſiderations it follows, that the object will be magnified the more, as the eye-glaſs is the ſegment of a ſmaller ſphere; but the field of viſion will be the greater, as the ſame is a ſegment of a larger ſphere. Therefore if two eye-glaſſes, the one a ſegment of a larger ſphere, the other of a ſmaller one, be ſo combined, as that the object appearing very near through them, i. e. not farther diſtant than the focus of the firſt, be yet diſtinct; the object, at the ſame time, will be vaſtly magnified, and the field of viſion much greater than if only one lens was uſed; and the object will be ſtill more magnified, and the field enlarged, if both the object-glaſs and eye-glaſs be double. But becauſe an object appears dim when viewed through ſo many glaſſes, part of the rays being reflected in paſſing through each, it is not adviſeable greatly to multiply glaſſes; ſo that, among compound Microſcopes, the beſt are thoſe which conſiſt of one object-glaſs, and two eye glaſſes.

Dr. Hook, in the preface to his Micrography, tells us, that in moſt of his obſervations he uſed a Microſcope of this kind, with a middle eye-glaſs of a conſiderable diameter, when he wanted to ſee much of the object at one view, and took it out when he would examine the ſmall parts of an object more accurately; for the fewer refractions there are, the more light and clear the object appears.

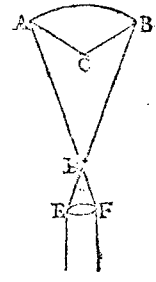
For a Microſcope of three lenſes De Chales recommends an object glaſs of $\frac{1}{3}$ or $\frac{1}{4}$ of a digit; and the firſt eye-glaſs he makes 2 or $2\frac{1}{2}$ digits; and the diſtance between the object-glaſs and eye-glaſs about 20 lines. Conradi had an excellent Microſcope, whoſe object-glaſs was half a digit, and the two eye-glaſſes (which were placed very near) 4 digits; but it anſwered beſt when, inſtead of the object-glaſs, he uſed two glaſſes, convex on both ſides, their ſphere about a digit and a half, and at moſt 2, and their convexities touching each other within the ſpace of half a line. Euſtachius de Divinis, inſtead of an object-glaſs convex on both ſides, uſed two plano-convex lenſes, whoſe convexities touched. Grindelius did the ſame; only that the convexities did not quite touch. Zahnius made a binocular Microſcope, with which both eyes were uſed. But the moſt commodious double Microſcope, it is ſaid, is that of our countryman Mr. Marſhal; though ſome improvement was made in it by Mr. Culpepper and Mr. Scarlet. Theſe are exhibited in figures 5 and 6.

It is obſerved, that compound Microſcopes ſometimes exhibit a fallacious appearance, by repreſenting convex objects concave, and vice verſa. Philoſ. Tranſ. numb. 476, pa. 387.

To fit Microſcopes, as well as Teleſcopes, to ſhort-ſighted eyes, the object-glaſs and the eye-glaſs muſt be placed a little nearer together, ſo that the rays of each pencil may not emerge parallel, but may fall diverging upon the eye.

Reflecting MICROSCOPE, is that which magnifies by reflection, as the foregoing ones do by refraction. The inventor of this Microſcope was Sir Iſaac Newton.

The ſtructure of ſuch a Microſcope may be conceived thus: near the focus of a concave ſpeculum AB, place a minute object C, that its image may be formed larger than itſelf in D; to the ſpeculum join a lens, convex on both ſides, EF, ſo as the image D may be in its focus.



The eye will here ſee the image inverted, but diſtinct, and enlarged; conſequently the object will be larger than if viewed through the lens alone.

Any teleſcope is changed into a Microſcope, by removing the object-glaſs to a greater diſtance from the eye-glaſs. And ſince the diſtance of the image is various, according to the diſtance of the object from the focus; and it is magnified the more, as its diſtance from the object-glaſs is greater; the ſame teleſcope may be ſucceſſively changed into Microſcopes which magnify the object in different degrees. See ſome inſtruments of this ſort deſcribed in Smith's Optics, Remarks, pa. 94.

Solar MICROSCOPE, called alſo the Camera Obſcura Microſcope, was invented by Mr. Lieberkuhn in 1738 or 1739, and conſiſts of a tube, a looking-glaſs, a convex lens, and a Wilſon's Microſcope. The tube (fig. 7) is braſs, near 2 inches in diameter, fixed in a circular collar of mahogany, with a groove on the outſide

ſide of its periphery, denoted by 2, 3, and connected by a cat-gut to the pulley 4 on the upper part; which turning round at pleaſure, by the pin 5 within, in a ſquare frame, may be eaſily adjuſted to a hole in the ſhutter of a window, by the ſcrews 1, 1, ſo cloſely that no light can enter the room but through the tube of the inſtrument. The mirror G is faſtened to the frame by hinges, on the ſide that goes without the window: this glaſs, by means of a jointed braſs wire, 6, 7, and the ſcrew H 8, coming through the frame, may be moved either vertically or horizontally, to throw the ſun's rays through the braſs tube into the darkened room. The end of the braſs tube without the ſhutter has a convex lens, 5, to collect the rays thrown on it by the glaſs G, and bring them to a focus in the other part, where D is a tube ſliding in and out, to adjuſt the object to a due diſtance from the focus. And to the end G of another tube F, is ſcrewed one of Wilſon's ſimple pocket Microſcopes, containing the object to be magnified in a ſlider; and by tube F, ſliding on the ſmall end E, of the other tube D, it is brought to a true focal diſtance.

The Solar Microſcope has been introduced into the ſmall and portable Camera Obſcura, as well as the large one: and if the image be received upon a piece of half-ground glaſs, ſhaded from the light of the ſun, it will be ſufficiently viſible. Mr. Lieberkuhn made conſiderable improvements in his Solar Microſcope, particularly in adapting it to the viewing of opaque objects; and M. Aepinus, Nov. Com. Petrop. vol. 9, pa. 326, has contrived, by throwing the light upon the foreſide of any object, before it is tranſmitted through the object lens, to repreſent all kinds of objects by it with equal advantage. In this improvement, the body of the common Solar Microſcope is retained, and only an addition made of two braſs plates, AB, AC, (fig 8), joined by a hinge, and held at a proper diſtance by a ſcrew. A ſection of theſe plates, and of all the neceſſary parts of the inſtrument, may be ſeen in fig. 9, where *a c* repreſent rays of the ſun converging from the illuminating lens, and falling upon the mirror *bd*, which is fixed to the nearer of the braſs plates. From this they are thrown upon the object at *ef*, and are thence tranſmitted through the object lens at K, and a perforation in the farther plate, upon a ſcreen, as uſual. The uſe of the ſcreen *n* is to vary the diſtance of the two plates, and thereby to adjuſt the mirror to the object with the greateſt exactneſs. M. Euler alſo contrived a method of introducing viſion by reflected light into this Microſcope.

The MICROSCOPE *for Opaque Objects* was alſo invented by M. Lieberkuhn, about the ſame time with the former, and remedies the inconvenience of having the dark ſide of an object next the eye; for by means of a concave ſpeculum of ſilver, highly poliſhed, having a magnifying lens placed in its centre, the object is ſo ſtrongly illuminated, that it may be examined with eaſe. A convenient apparatus of this kind, with 4 different ſpeculums and magnifiers of different powers, was brought to perfection by Mr. Cuff. Philoſ. Tranſ. number 458, § 9.

MICROSCOPIC *Objects*. All things too minute to be viewed diſtinctly by the naked eye, are proper objects for the Microſcope. Dr. Hook has diſtinguiſhed them into theſe three general kinds; viz, exceeding ſmall bodies, exceeeding ſmall pores, or exceeding ſmall motions. The ſmall bodies may be ſeeds, inſects, animalcules, ſands, ſalts, &c: the pores may be the interſtices between the ſolid parts of bodies, as in ſtones, minerals, ſhells, &c. or the mouths of minute veſſels in vegetables, or the pores of the ſkin, bones, and other parts of animals: the ſmall motions, may be the movements of the ſeveral parts or members of minute animals, or the motion of the fluids, contained either in animal or vegetable bodies. Under one or other of theſe three general heads, almoſt every thing about us affords matter of obſervation, and may conduce both to our amuſement and inſtruction.

Great caution is to be uſed in forming a judgment on what is ſeen by the Microſcope, if the objects are extended or contracted by force or dryneſs.

Nothing can be determined about them, without making the proper allowances; and different lights and poſitions will often ſhew the ſame object as very different from itſelf. There is no advantage in any greater magnifier than ſuch as is capable of ſhewing the object in view diſtinctly; and the leſs the glaſs magnifies, the more pleaſantly the object is always ſeen.

The colours of objects are very little to be depended on, as ſeen by the Microſcope; for their ſeveral component particles, being thus removed to great diſtances from one another, may give reflections very different from what they would, if ſeen by the naked eye.

The motions of living creatures too, or of the fluids contained in their bodies, are by no means to be haſtily judged of, from what we ſee by the Microſcope, without due conſideration; for as the moving body, and the ſpace in which it moves, are magnified, the motion muſt alſo be magnified; and therefore that rapidity with which the blood ſeems to paſs through the veſſels of ſmall animals, muſt be judged of accordingly. Baker on the Microſcope, pa. 52, 62, &c. See alſo an elegant work on this ſubject, lately publiſhed by that ingenious optician Mr. George Adams.

MIDDLE *Latitude*, is half the ſum of two given latitudes; or the arithmetical mean, or the middle between two parallels of latitude. Therefore,

If the latitudes be of the ſame name, either both north or both ſouth, add the one number to the other, and divide the ſum by 2; the quotient is the middle latitudes, which is of the ſame name with the two given latitudes. But

If the latitudes be of different names, the one north and the other ſouth; ſubtract the leſs from the greater, and divide the remainder by 2, ſo ſhall the quotient be the middle latitude, of the ſame name with the greater of the two.

Ex. 1.			*Ex.* 2.		
One lat.	35° 27′	N.		35° 27′	S.
the other	21 13	N.		21 13	N.
2)	56 40		2)	14 14	
Mid. lat.	28 20	N.	Mid. lat.	7 7	S.

MIDDLE *Latitude Sailing*, is a method of reſolving the caſes of globular ſailing, by means of the Middle Latitude, on the principles of plane and parallel ſailing jointly.

This method is not quite accurate, yet often agrees pretty nearly with Mercator's Sailing, and is founded on the following principle, viz, That the departure is accounted a meridional diſtance in the middle latitude between the latitude ſailed from and the latitude arrived at.

This artifice ſeems to have been invented, on account of the eaſy manner in which the ſeveral caſes may be reſolved by the Traverſe Table, and to ſerve where a table of meridional parts is wanting. It is ſufficiently near the truth either when the two parallels are near the equator, or not far diſtant from one another, in any latitude. It is performed by theſe two rules:

1. As the coſine of the middle latitude:
   Is to radius ::
   So is the departure :
   To the difference of longitude .
2. As the coſine of the middle latitude:
   Is to the tangent of the courſe ::
   So is the difference of latitude :
   To the difference of longitude .

Ex. A ſhip ſails from latitude 37° north, ſteering conſtantly N. 33° 19′ eaſt, for 8 days, when ſhe was found in latitude 51° 18′ north; required her difference of longitude.

	51° 18′		51° 18′
	37 00		37 00
2)	88 18	Diff. lat.	14 18 = 858 m.

As cos. mid. l.	44 09	-	0·14417
To tang. cour.	33 19	-	9·81776
So diff. lat.	858	-	2·93349
To diff. long.	786	-	2·89542

or 13° 6′ diff. of long. ſought.

MIDDLE *Region.* See REGION.

MID-HEAVEN, *Medium Cœli*, is that point of the ecliptic which culminates, or is higheſt, or is in the meridian at any time.

MIDSUMMER-*Day*, is held on the 24th of June, the ſame day as the Nativity of St. John the Baptiſt is held.

MILE, a long meaſure, by which the Engliſh, Italians, and ſome other nations, uſe to expreſs the diſtance between places: the ſame as the French uſe the word *League*.

The Mile is of different lengths in different countries. The geographical, or Italian Mile, contains 1000 geometrical paces, *mille paſſus*, whence the term Mile is derived. The Engliſh Mile conſiſts of 8 furlongs, each furlong of 40 poles, and each pole of 16½ feet: ſo that the Mile is = 8 furlongs = 320 poles = 1760 yards = 5280 feet.

The following table ſhews the length of the Mile, or league, in the principal nations of Europe, expreſſed in geometrical paces:

	Geomet. Paces.
Mile of Ruſſia - -	750
of Italy - -	1000
of England , -	1200
of Scotland and Ireland	1500
Old League of France - -	1500
Small League, ibid. -	2000
Mean League of France - -	2500
Great League, ibid. - -	3000
Mile of Poland - -	3000
of Spain - -	3428
of Germany - -	4000
of Sweden - -	5000
of Denmark - -	5000
of Hungary - -	6000

MILITARY *Architecture.* The ſame with Fortification.

MILKY WAY, *Via Lactea*, or *Galaxy*, a broad track or path, encompaſſing the whole heavens, diſtinguiſhable by its white appearance, whence it obtains the name. It extends itſelf in ſome parts by a double path, but for the moſt part it is ſingle. Its courſe lies through the conſtellations Caſſiopeia, Cygnus, Aquila, Perſeus, Andromeda, part of Ophiucus and Gemini, in the northern hemiſphere; and in the ſouthern, it takes in part of Scorpio, Sagittarius, Centaurus, the Argonavis, and the Ara. There are ſome traces of the ſame kind of light about the ſouth pole, but they are ſmall in compariſon of this: theſe are called by ſome, luminous ſpaces, and Magellanic clouds; but they ſeem to be of the ſame kind with the Milky way.

The Milky way has been aſcribed to various cauſes. The Ancients fabled, that it proceeded from a ſtream of milk, ſpilt from the breaſt of Juno, when ſhe puſhed away the infant Hercules, whom Jupiter laid to her breaſt to render him immortal. Some again, as Ariſtotle, &c, imagined that this path conſiſted only of a certain exhalation hanging in the air; while Metrodorus, and ſome Pythagoreans, thought the ſun had once gone in this track, inſtead of the ecliptic; and conſequently that its whiteneſs proceeds from the remains of his light. But it is now well known, by the help of teleſcopes, that this track in the heavens conſiſts of an immenſe multitude of ſtars, ſeemingly very cloſe together, whoſe mingled light gives this appearance of whiteneſs; by Milton beautifully deſcribed as a path "powdered with ſtars."

MILL, properly denotes a machine for grinding corn, &c; but in a more general ſignification, is applied to all machines whoſe action depends on a circular motion. Of theſe there are ſeveral kinds, according to the various methods of applying the moving power; as water-mills, wind-mills, horſe-mills, hand-mills, &c, and even ſteam-mills, or ſuch as are worked by the force of ſteam; as that noble ſtructure that was erected near Blackfriars Bridge, called the Albion Mills, but lately deſtroyed by fire.

The water acts both by its impulſe and weight in an overſhot water-mill, but only by its impulſe in an undershot one; but here the velocity is greater, becauſe the water is ſuffered to deſcend to a greater depth before it ſtrikes the wheel. Mr. Fergúſon obſerves, that where there is but a ſmall quantity of water, and a fall great enough for the wheel to lie under it, the bucket or overſhot wheel is always uſed: but where there is a large body of water, with a little fall, the breaſt or float-board wheel muſt take place: and where there is a large ſupply of water, as a river, or large ſtream or brook, with very little fall, then the undershot wheel is the eaſieſt, cheapeſt, and moſt ſimple ſtructure.

Dr.

Dr. Deſaguliers, having had occaſion to examine many underſhot and overſhot Mills, generally found that a well made overſhot Mill ground as much corn, in the ſame time, as an underſhot Mill does with ten times as much water; ſuppoſing the fall of water at the overſhot to be 20 feet, and at the underſhot about 6 or 7 feet: and he generally obſerved that the wheel of the overſhot Mill was of 15 or 16 feet diameter, with a head of water of 4 or 5 feet, to drive the water into the buckets with ſome momentum.

In Water-mills, ſome few have given the preference to the underſhot wheel, but moſt writers prefer the overſhot one. M. Belidor greatly preferred the underſhot to any other conſtruction. He had even concluded, that water applied in this way will do more than ſix times the work of an overſhot wheel; while Dr. Deſaguliers, in overthrowing Belidor's poſition, determined that an overſhot wheel would do ten times the work of an underſhot wheel with an equal quantity of water. So that between theſe two celebrated authors, there is a difference of no leſs than 60 to 1. In conſequence of ſuch monſtrous diſagreement, Mr. Smeaton began the courſe of experiments mentioned below.

In the Philoſ. Tranſ. vol. 51, for the year 1759, we have a large paper with experiments on Mills turned both by water and wind, by that ingenious and experienced engineer Mr. Smeaton. From thoſe experiments it appears, pa. 129, that the effects obtained by the overſhot wheel are generally 4 or 5 times as great as thoſe with the underſhot wheel, in the ſame time, with the ſame expence of water, deſcending from the ſame height above the bottom of the wheels; or that the former performs the ſame effect as the latter, in the ſame time, with an expence of only one-4th or one-5th of the water, from the ſame head or height. And this advantage ſeems to ariſe from the water lodging in the buckets, and ſo carrying the wheel about by their weight. But, in pa. 130, Mr. Smeaton reckons the effect of overſhot only double to that of the underſhot wheel. And hence he infers, in general, "that the higher the wheel is in proportion to the whole deſcent, the greater will be the effect; becauſe it depends leſs upon the impulſe of the head, and more upon the gravity of the water in the buckets. However, as every thing has its limits, ſo has this; for thus much is deſirable, that the water ſhould have ſomewhat greater velocity, than the circumference of the wheel, in coming thereon; otherwiſe the wheel will not only be retarded, by the buckets ſtriking the water, but thereby daſhing a part of it over, ſo much of the power is loſt." He is farther of opinion, that the beſt velocity for an overſhot wheel is when its circumference moves at the rate of about 3 feet in a ſecond of time. See WIND MILL.

Conſiderable differences have alſo ariſen as to the mathematical theory of the force of water ſtriking the floats of a wheel in motion. M. Parent, Maclaurin, Deſaguliers, &c, have determined, by calculation, that a wheel works to the greateſt effect, when its velocity is equal to one-third of the velocity of the water which ſtrikes it; or that the greateſt velocity that the wheel acquires, is one-third of that of the water. And this determination, which has been followed by all mathematicians till very lately, neceſſarily reſults from a poſition which they aſſume, viz, that the force of the water againſt the wheel, is proportional to the ſquare of its relative velocity, or of the difference between the abſolute velocity of the water and that of the wheel. And this poſition is itſelf an inference which they make from the force of water ſtriking a body at reſt, being as the ſquare of the velocity, becauſe the force of each particle is as the velocity it ſtrikes with, and the number of particles or the whole quantity that ſtrikes is alſo as the ſame velocity. But when the water ſtrikes a body in motion, the quantity of it that ſtrikes is ſtill as the abſolute velocity of the water, though the force of each particle be only as the relative velocity, or that with which it ſtrikes. Hence it follows, that the whole force or effect is in the compound ratio of the abſolute and relative velocities of the water; and therefore is greater than the before mentioned effect or force, in the ratio of the abſolute to the relative velocity. The effect of this correction is, that the maximum velocity of the wheel becomes one-half the velocity of the water, inſtead of one-third of it only: a determination which nearly agrees with the beſt experiments, as thoſe of Mr. Smeaton.

This correction has been lately made by Mr. W. Waring, in the 3d volume of the Tranſactions of the American Philoſophical Society, pa. 144. This ingenious writer ſays, 'Being lately requeſted to make ſome calculations relative to Mills, particularly Dr. Barker's conſtruction as improved by James Rumſey, I found more difficulty in the attempt than I at firſt expected. It appeared neceſſary to inveſtigate new theorems for the purpoſe, as there are circumſtances peculiar to this conſtruction, which are not noticed, I believe, by any author; and the theory of Mills, as hitherto publiſhed, is very imperfect, which I take to be the reaſon it has been of ſo little uſe to practical mechanics.

'The firſt ſtep, then, toward calculating the power of any water-mill (or wind-mill) or proportioning their parts and velocities to the greateſt advantage, ſeems to be,

'*The Correction of an Eſſential Miſtake adopted by Writers on the Theory of Mills.*

'This is attempted with all the deference due to eminent authors, whoſe ingenious labours have juſtly raiſed their reputation and advanced the ſciences; but when any wrong principles are ſucceſſively publiſhed by a ſeries of ſuch pens, they are the more implicitly received, and more particularly claim a public rectification; which muſt be pleaſing, even to theſe candid writers themſelves.'

A very ingenious writer in England, 'in his maſterly treatiſe on the rectilinear motion and rotation of bodies, publiſhed ſo lately as 1784, continues this overſight, with its pernicious conſequences, through his propoſitions and corollaries (pa. 275 to 284), although he knew the theory was ſuſpected: for he obſerves (pa. 382) "Mr. Smeaton in his paper on mechanic "power (publiſhed in the Philoſophical Tranſactions "for the year 1776)' allows, that the theory uſually "given will not correſpond with matter of fact, when "compared with the motion of machines; and ſeems "to attribute this diſagreement, rather to deficiency "in the theory, than to the obſtacles which have pre-

" vented the application of it to the complicated mo-
" tion of engines, &c. In order to ſatisfy himſelf con-
" cerning the reaſon of this diſagreement, he conſtruct-
" ed a ſet of experiments, which, from the known
" abilities and ingenuity of the author, certainly de-
" ſerve great conſideration and attention from every
" one who is intereſted in theſe inquiries." ' And notwithſtanding the ſame learned author ſays, " The evidence upon which the theory reſts is ſcarcely leſs than mathematical;" I am ſorry to find, in the preſent ſtate of the ſciences, one of his abilities concluding (pa. 380) " It is not probable that the theory of motion, however inconteſtible its principles may be, can afford much aſſiſtance to the practical mechanic," although indeed his theory, compared with the above cited experiments, might ſuggeſt ſuch an inference. But to come to the point, I would juſt premiſe theſe

Definitions.

' If a ſtream of water impinge againſt a wheel in motion, there are three different velocities to be conſidered, appertaining thereto, viz,

Firſt, the abſolute velocity of the water;
Second, the abſolute velocity of the wheel;
Third, the relative velocity of the water to that of the wheel,

i. e. the difference of the abſolute velocities, or the velocity with which the water overtakes or ſtrikes the wheel.'

' Now the miſtake conſiſts in ſuppoſing the momentum or force of the water againſt the wheel, to be in the *duplicate ratio of the relative velocity:* Whereas,

PROP. I.

' The force of an Invariable Stream, impinging againſt a Mill-wheel in Motion, is in the *Simple Direct Proportion of the Relative Velocity.*'

' For, if the relative velocity of a fluid againſt a ſingle plane be varied, either by the motion of the plane, or of the fluid from a given aperture, or both, then, the number of particles acting on the plane in a given time, and likewiſe the momentum of each particle, being reſpectively as the relative velocity, the force on both theſe accounts, muſt be in the *duplicate* ratio of the relative velocity, agreeably to the common theory, with reſpect to this *ſingle plane:* but, the number of theſe planes, or parts of the wheel acted on in a given time, will be as the velocity of the wheel, or *inverſely as the relative velocity;* therefore, the moving force of the wheel muſt be in the ſimple direct ratio of the relative velocity. Q. E. D.

' Or the propoſition is manifeſt from this conſideration; that, while the ſtream is invariable, whatever be the velocity of the wheel, the ſame number of particles or quantity of the fluid, muſt ſtrike it ſomewhere or other in a given time; conſequently the variation of force is *only* on account of the varied impingent velocity of the ſame body, occaſioned by a change of motion in the wheel; that is, the momentum is as the relative velocity.'

' Now, this true principle ſubſtituted for the erroneous one in uſe, will bring the theory to agree remarkably with the notable experiments of the ingenious Smeaton, before mentioned, publiſhed in the Philoſophical Tranſactions of the Royal Society of London for the year 1751, vol. 51, for which the honorary annual medal was adjudged by the ſociety, and preſented to the author by their preſident. An inſtance or two of the importance of this correction may be adduced as below.'

PROP. II.

' The velocity of a wheel, moved by the impact of a ſtream, muſt be half the velocity of the fluid, to produce the greateſt poſſible effect.—For let

V = the velocity, m = the momentum of the fluid;
v = the velocity, p = the power of the wheel.

Then $V - v$ = the relative velocity, by def. 3d;

and as $V : V - v :: m : \frac{m}{V} \times \overline{V - v} = p$ (prop. 1);

this multiplied by v, gives $pv = \frac{m}{V} \times \overline{Vv - v^2}$ = a maximum; hence $Vv - v^2$ = a maximum, and its fluxion (v being the variable quantity) is $V\dot{v} - 2v\dot{v} = 0$; therefore $v = \frac{1}{2}V$, that is, the velocity of the wheel = half that of the fluid, at the place of impact, when the effect is a maximum. Q. E. D.'

' The uſual theory gives $v = \frac{1}{3}V$; where the error is not leſs than one third of the true velocity of the wheel.'

' This propoſition is applicable to underſhot wheels, and correſponds with the accurate experiments before cited, as appears from the author's concluſion (Philoſ. Tranſ. for 1776, pa. 457), viz, " The velocity of the " wheel, which according to M. Parent's determina-
" tion, adopted by Deſaguliers and Maclaurin, ought to
" be no more than one third of that of the water, varies
" at the maximum in the experiments of table 1, be-
" tween one third and one half; but in all the caſes
" there related, in which the moſt work is performed
" in proportion to the water expended, and which ap-
" proach the neareſt to the circumſtances of great
" works when properly executed, the maximum lies
" much nearer one half than one third, *one half ſeeming*
" *to be the true maximum*, if nothing were loſt by the
" reſiſtance of the air, the ſcattering of the water car-
" ried up by the wheel, &c." Thus he fully ſhews the common theory to have been very defective; but, I believe, none have ſince pointed out wherein the deficiency lay, nor how to correct it; and now we ſee the agreement of the true theory with the reſult of his experiments.' For another problem,

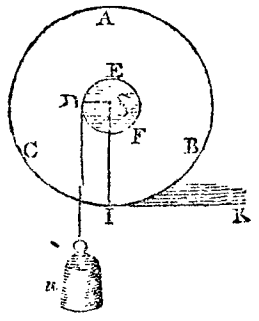
PROB. III.

' Given, the momentum (m) and velocity (V) of the fluid at I, the place of impact; the radius ($R = IS$) of the wheel ABC; the radius ($r = DS$) of the ſmall wheel DEF on the ſame axle or ſhaft; the weight (w) or reſiſtance to be overcome at D, and the friction (f) or force neceſſary to move the wheel without the weight; required the velocity (v) of the wheel &c."

' Here we have $V : V - v :: m : m \times \frac{V - v}{V} =$ the acting force at I in the direction KI, as before (prop. 2). Now $R : r :: w : \frac{rw}{R}$ = the power

at

at I neceſſary to counterpoiſe the weight w; hence $\frac{rw}{R} + f =$ the whole reſiſtance oppoſed to the action



of the fluid at I; which deducted from the moving force, leaves $m \times \frac{V-v}{V} - \frac{rw}{R} - f =$ the accelerating force of the machine; which, when the motion becomes uniform, will be evaneſcent or $= 0$; therefore $m \times \frac{V-v}{V} = \frac{rw}{R} + f$, which gives

$v = V \times 1 - \frac{rw}{mR} - \frac{f}{m} =$ the true velocity required; or, if we reject the friction, then

$v = V \times 1 - \frac{rw}{mR}$ is the theorem for the velocity of the wheel. This, by the common theory, would be $v = V \times 1 - \sqrt{\frac{rw}{mR}}$, which is too little by

$V\sqrt{\frac{rw}{mR}} - V\frac{rw}{mR}$. No wonder why we have hitherto derived ſo little advantage from the theory.'

'Corol. 1. If the weight (w) or reſiſtance be required, ſuch as juſt to admit of that velocity which would produce the greateſt effect; then, by ſubſtituting $\frac{1}{2}V$ for its equivalent v (by prop. 2), we have $\frac{1}{2}V = V \times 1 - \frac{rw}{mR} - \frac{f}{m}$; hence $w = \frac{\frac{1}{2}m-f}{r} \times R$; or, if $f = 0$, $w = \frac{mR}{2r}$; but theoriſts make this $\frac{4mR}{9r}$, where the error is $\frac{mR}{18r}$.'

'Corol. 2. We have alſo $r = \frac{\frac{1}{2}m-f}{w} \times R$; or, rejecting friction, $r = \frac{mR}{2w}$, when the greateſt effect is produced, inſtead of $r = \frac{4mR}{9w}$, as has been ſuppoſed: this is an important theorem in the conſtruction of mills.'

In the ſame volume of the American Tranſactions, pa. 185, is another ingenious paper, by the ſame author, on the power and machinery of Dr. Barker's Mill, as improved by Mr. James Rumſey, with a deſcription of it. This is a Mill turned by the reſiſting force of a ſtream of water that iſſues from an orifice, the rotatory part, in which that orifice is, being impelled the contrary way by its reaction againſt the ſtream that iſſues from it.

Mr. Ferguſon has given the following directions for conſtructing water mills in the beſt manner; with a table of the ſeveral correſponding dimenſions proper to a great variety of perpendicular falls of the water.

When the float-boards of the water-wheel move with a 3d part of the velocity of the water that acts upon them, the water has the greateſt power to turn the Mill: and when the millſtone makes about 60 turns in a minute, it is found to perform its work the beſt: for, when it makes but about 40 or 50, it grinds too ſlowly; and when it makes more than 70, it heats the meal too much, and cuts the bran ſo ſmall that a great part of it mixes with the meal, and cannot be ſeparated from it by ſifting or boulting. Conſequently the utmoſt perfection of mill-work lies in making the train ſo as that the millſtone ſhall make about 60 turns in a minute when the water wheel moves with a 3d part of the velocity of the water. To have it ſo, obſerve the following rules:

1. Meaſure the perpendicular height of the fall of water, in feet, above the middle of the aperture, where it is let out to act by impulſe againſt the float-boards on the loweſt ſide of the underſhot wheel.

2. Multiply that height of the fall in feet by the conſtant number $64\frac{1}{4}$, and extract the ſquare root of the product, which will be the velocity of the water at the bottom of the fall, or the number of feet the water moves per ſecond.

3. Divide the velocity of the water by 3; and the quotient will be the velocity of the floats of the wheel in feet per ſecond.

4. Divide the circumference of the wheel in feet, by the velocity of its floats; and the quotient will be the number of ſeconds in one turn or revolution of the great water-wheel, on the axis of which is fixed the cog-wheel that turns the trundle.

5. Divide 60 by the number of ſeconds in one turn of the water-wheel or cog-wheel; and the quotient will be the number of turns of either of theſe wheels in a minute.

6. Divide 60 (the number of turns the millſtone ought to have in a minute) by the abovemſaid number of turns; and the quotient will be the number of turns the millſtone ought to have for one turn of the water or cog-wheel. Then,

7. As the required number of turns of the millſtone in a minute is to the number of turns of the cog-wheel in a minute, ſo muſt the number of cogs in the wheel be to the number of ſtaves or rounds in the trundle on the axis of the millſtone, in the neareſt whole number that can be found.

By theſe rules the following table is calculated; in which, the diameter of the water-wheel is ſuppoſed 18 feet, and conſequently its circumference $56\frac{1}{2}$ feet, and the diameter of the millſtone is 5 feet.

The Mill-Wright's Table.

Perpendicular height of the fall of water.	Velocity of the water in feet per ſecond.	Velocity of the wheel in feet per ſecond.	Number of turns of the wheel in a minute.	Required no. of turns of the millſtone for each turn of the wheel.	Neareſt number of cogs and ſtaves for that purpoſe. Cogs.	Staves.	Number of turns of the millſtone for one turn of the wheel by theſe cogs and ſtaves.	Number of turns of the millſtone in a minute by theſe cogs and ſtaves.

For the theory and conſtruction of Wind-mills, ſee WIND-*mill*.

MILLION, the number of ten hundred thouſand, or a thouſand times a thouſand.

MINE, in Fortification &c, is a ſubterraneous canal or paſſage, dug under any place or work intended to be blown up by gunpowder. The paſſage of a mine leading to the powder is called the *Gallery*; and the extremity, or place where the powder is placed, is called the *Chamber*. The line drawn from the centre of the chamber perpendicular to the neareſt ſurface, is called the *Line of leaſt Reſiſtance*; and the pit or hole, made by the mine when ſprung, or blown up, is called the *Excavation*.

The Mines made by the beſiegers in the attack of a place, are called ſimply *Mines*; and thoſe made by the beſieged, *Counter-mines*.

The fire is conveyed to the Mine by a pipe or hoſe, made of coarſe cloth, of about an inch and half in diameter, called *Sauciſſon*, extending from the powder in the chamber to the beginning or entrance of the gallery, to the end of which is fixed a match, that the miner who ſets fire to it may have time to retire before it reaches the chamber.

It is found by experiments, that the figure of the excavation made by the exploſion of the powder, is nearly a paraboloid, having its focus in the centre of the powder, and its axis the line of leaſt reſiſtance; its diameter being more or leſs according to the quantity of the powder, to the ſame axis, or line of leaſt reſiſtance. Thus, M. Belidor lodged ſeven different quantities of powder in as many different mines, of the ſame depth, or line of leaſt reſiſtance 10 feet; the charges and greateſt diameters of the excavation, meaſured after the exploſion, were as follow:

	Powder.	Diam.
1ſt -	120lb -	$22\frac{2}{3}$ feet
2d -	160 -	26
3d -	200 -	29
4th -	240 -	$31\frac{1}{4}$
5th -	280 -	$33\frac{1}{2}$
6th -	320 -	36
7th -	360 -	38

From which experiments it appears that the excavation, or quantity of earth blown up, is in the ſame proportion with the quantity of powder; whence the charge of powder neceſſary to produce any other propoſed effect, will be had by the rule of Proportion.

MINE-*Dial*, is a box and needle, with a braſs ring divided into 360 degrees, with ſeveral dials graduated upon it, commonly made for the uſe of miners.

MINUTE, is the 60th part of a degree, or of an hour. The minutes of a degree are marked with the acute accent, thus $'$; the ſeconds by two, $''$; the thirds by three, $'''$. The minutes, ſeconds, thirds, &c, in time, are ſometimes marked the ſame way; but, to avoid confuſion, the better way is, by the initials of the words; as minutes ^{m}, ſeconds ^{s}, thirds ^{t}, &c.

MINUTE, in Architecture, uſually denotes the 60th part of a module, but ſometimes only the 30th part.

MIRROR, a ſpeculum, looking-glaſs, or any poliſhed body, whoſe uſe is to form the images of diſtinct objects by reflexion of the rays of light.

Mirrors are either plane, convex, or concave. The firſt ſort reflects the rays of light in a direction exactly ſimilar to that in which they fall upon it, and therefore repreſents bodies of their natural magnitude. But the convex ones make the rays diverge much more than before reflexion, and therefore greatly diminiſh the images of thoſe objects which they exhibit: while the concave ones, by collecting the rays into a focus, not only magnify the objects they ſhew, but will alſo burn very fiercely when expoſed to the rays of the ſun; and hence they are commonly known by the name of *burning Mirrors*.

In ancient times the Mirrors were made of ſome kind of metal; and from a paſſage in the Moſaic writings we learn, that the Mirrors uſed by the Jewiſh women, were made of braſs; a practice doubtleſs learned from the Egyptians.

Any kind of metal, when well poliſhed, will reflect very powerfully; but of all others, ſilver reflects the moſt, though it has always been too expenſive a material for common uſe. Gold is alſo very powerful; and all metals, or even wood, gilt and poliſhed, will act very powerfully as burning Mirrors. Even poliſhed ivory, or ſtraw nicely plaited together, will form Mirrors capable of burning, if on a large ſcale.

Since the invention of glaſs, and the application of quickſilver to it, have become generally known, it has been univerſally employed for thoſe plane Mirrors uſed as ornaments to houſes; but in making reflecting teleſcopes they have been found much inferior to metallic ones. It does not appear however that the ſame ſuperiority belongs to the metallic burning Mirrors, conſidered merely as burning ſpeculums; ſince the Mirror with which Mr. Macquer melted platina, though only 22 inches diameter, and made of quickſilvered glaſs, produced much greater effects than M. Villette's metal ſpeculum, which was of a much larger ſize. It is very probable, however, that M. Villette's Mirror was not ſo well poliſhed as it ought to have been; as the art of preparing the metal for taking the fineſt poliſh, has but lately been diſcovered, and publiſhed in the Philoſ. Tranſactions, by Dr. Mudge of Plymouth, and, after him, by Mr. Edwards, Dr. Herſchel, &c.

Some of the more remarkable laws and phenomena of plane Mirrors, are as follow:

1. A ſpectator will ſee his image of the ſame ſize, and erect, but reverſed as to right and left, and as far beyond the ſpeculum as he is before it. As he moves to or from the ſpeculum, his image will, at the ſame time, move towards or from the ſpeculum alſo on the other ſide. In like manner if, while the ſpectator is at reſt, an object be in motion, its image behind the ſpeculum will be ſeen to move at the ſame rate. Alſo when the ſpectator moves, the images of objects that are at reſt will appear to approach or recede from him, after the ſame manner as when he moves towards real objects.

2. If ſeveral Mirrors, or ſeveral fragments or pieces of Mirrors, be all diſpoſed in the ſame plane, they will only exhibit an object once.

3. If two plane Mirrors, or ſpeculums, meet in any angle, the eye, placed within that angle, will ſee the image of an object placed within the ſame, as often repeated as there may be perpendiculars drawn determining the places of the images, and terminated without the angle. Hence, as the more perpendiculars, terminated without the angle, may be drawn as the angle is more acute; the acuter the angle, the more numerous the images. Thus, Z. Traber found, at an angle of one-3d of a circle, the image was repreſented twice, at $\frac{1}{4}$th thrice, at $\frac{1}{6}$th five times, and at $\frac{1}{12}$th eleven times.

Farther, if the Mirrors be placed upright, and ſo contracted; or if you retire from them, or approach to them, till the images reflected by them coaleſce, or run into one, they will appear monſtrouſly diſtorted. Thus, if they be at an angle ſomewhat greater than a right one, the image of one's face will appear with only one eye; if the angle be leſs than a right one, you will ſee 3 eyes, 2 noſes, 2 mouths, &c. At an angle ſtill leſs, the body will have two heads. At an angle ſomewhat greater than a right one, at the diſtance of 4 feet, the body will be headleſs, &c. Again, if the Mirrors be placed, the one parallel to the horizon, the other inclined to it, or declined from it, it is eaſy to perceive that the images will be ſtill more romantic. Thus, one being declined from the horizon to an angle of 144 degrees, and the other inclined to it, a man ſees himſelf ſtanding with his head to another's feet.

Hence it appears how Mirrors may be managed in gardens, &c, ſo as to convert the images of thoſe near them into monſters of various kinds; and ſince glaſs Mirrors will reflect the image of a lucid object twice or thrice, if a candle, &c, be placed in the angle between two Mirrors, it will be multiplied a great number of times.

Laws of Convex MIRRORS.

1. In a ſpherical convex Mirror, the image is leſs than the object. And hence the uſe of ſuch Mirrors in the art of painting, where objects are to be repreſented leſs than the life.

2. In a convex Mirror, the more remote the object, the leſs its image; alſo the ſmaller the Mirror, the leſs the image.

3. In a convex Mirror, the right hand is turned to the left, and the left to the right; and magnitudes perpendicular to the Mirror appear inverted.

4. The image of a right line, perpendicular to the Mirror, is a right line; but that of a right line oblique or parallel to the Mirror, is convex.

5. Rays reflected from a convex Mirror, diverge more than if reflected from a plane Mirror; and the ſmaller the ſphere, the more the rays diverge.

Laws of Concave MIRRORS.

The effects of concave Mirrors are, in general, the reverſe of thoſe of convex ones; rays being made to converge more, or diverge leſs than in plane Mirrors; the image is magnified, and the more ſo as the ſphere is ſmaller; &c, &c.

MITRE, in Architecture, is the workmen's term for an angle that is juſt 45 degrees, or half a right angle. And if the angle be the half of this, or a quarter of a right angle, they call it a *half-mitre*.

MIXT *Angle*, or *Figure*, is one contained by both right and curved lines.

MIXT *Number*, is one that is partly an integer, and partly a fraction; as $3\frac{1}{2}$.

MIXT *Ratio*, or *Proportion*, is when the sum of the antecedent and consequent is compared with the difference of the antecedent and consequent;

as if $\begin{cases} 4 : 3 :: 12 : 9 \\ a : b :: c : d \end{cases}$

then $\begin{cases} 7 : 1 :: 21 : 3 \\ a + b : a - b :: c + d : c - d. \end{cases}$

MOAT, in Fortification, a deep trench dug round a town or fortress, to be defended, on the outside of the wall, or rampart.

The breadth and depth of a Moat often depend on the nature of the soil; according as it is marshy, rocky, or the like. The brink of the Moat next the rampart, is called the Scarp; and the opposite side, the Counterscarp.

Dry MOAT, is one that is without water; which ought to be deeper than one that has water, called a Wet Moat. A Dry Moat, or one that has a little water, has often a small notch or ditch run all along the middle of its bottom, called a Cuvette.

Flat-bottomed MOAT, is that which has no sloping, its corners being somewhat rounded.

Lined MOAT, is that whose scarp and counterscarp are cased with a wall of mason's work lying aslope.

MOBILE, *Primum*, in the Ancient Astronomy, was a 9th heaven, or sphere, conceived above those of the planets and fixed stars. It was supposed that this was the first mover, and carried all the lower spheres about with it; by its rapidity communicating to them a motion carrying them round in 24 hours. But the diurnal apparent revolution of the heavens is now better accounted for, by the rotation of the earth on its axis, without the assistance of any such Primum Mobile.

MOBILITY, an aptitude or facility to be moved.

The Mobility of Mercury is owing to the smallness and sphericity of its particles; and these also render its fixation so difficult.

The hypothesis of the Mobility of the earth is the most plausible, and is universally admitted by the later astronomers.

Pope Paul V. appointed commissioners to examine the opinion of Copernicus touching the Mobility of the earth. The result of their enquiry was, a prohibition to assert, not that the Mobility was possible, but that it was really true: that is, they allowed the Mobility of the earth to be held as an hypothesis, which gives an easy and sensible solution of the phenomena of the heavenly motions; but forbade the Mobility of the earth to be maintained as a thesis, or real effective thing; because they conceived it contrary to Scripture.

MODILLIONS, small inverted consoles under the soffit or bottom of the drip, or of the corniche, seeming to support the projecture of the larmier, in the Ionic, Composite, and Corinthian orders.

MODULE, or Little Measure, in Architecture, a certain measure, taken at pleasure, for regulating the proportions of columns, and the symmetry or distribution of the whole building. Architects usually choose the diameter, or the semidiameter, of the bottom of the column, for their Module; which they subdivide into minutes; for estimating all the other parts of the building by.

MOINEAU, a flat bastion raised before a curtin when it is too long, and the bastions of the angles too remote to be able to defend one another. Sometimes the Moineau is joined to the curtin, and sometimes it is divided from it by a moat. Here musquetry are placed to fire each way.

MOLYNEUX (WILLIAM), an excellent mathematician and astronomer, was born at Dublin in 1656. After the usual grammar education, which he had at home, he was entered of the university of that city. Here he distinguished himself by the probity of his manners, as well as by the strength of his parts; and having made a remarkable progress in academical learning, and particularly in the new philosophy, as it was then called, after four years spent in this university, he was sent over to London, where he was admitted into the Middle Temple in 1675. Here he spent three years, in the study of the laws of his country. But the bent of his genius lay strongly toward mathematical and philosophical studies; and even at the university he conceived a dislike to scholastic learning, and fell into the methods of lord Bacon.

Returning to Ireland in 1678, he shortly after married Lucy the daughter of Sir William Domville, the king's attorney-general. Being master of an easy fortune, he continued to indulge himself in prosecuting such branches of natural and experimental philosophy as were most agreeable to his fancy; in which astronomy having the greatest share, he began, about 1681, a literary correspondence with Mr. Flamsteed, the king's astronomer, which he kept up for several years. In 1683 he formed a design of erecting a Philosophical Society at Dublin, in imitation of the Royal Society at London; and, by the countenance and encouragement of Sir William Petty, who accepted the office of president, began a weekly meeting that year, when our author was appointed their first secretary.

Mr. Molyneux's reputation for learning recommended him, in 1684, to the notice and favour of the first great duke of Ormond, then lord-lieutenant of Ireland; by whose influence chiefly he was appointed that year, jointly with sir William Robinson, surveyor-general of the king's buildings and works, and chief engineer.

In 1685, he was chosen fellow of the Royal Society at London; and that year he was sent by the government to view the most considerable fortresses in Flanders. Accordingly he travelled through that country and Holland, with part of Germany and France; and carrying with him letters of recommendation from Flamsteed to Cassini, he was introduced to him, and others, the most eminent astronomers in the several places through which he passed.

Soon after his return from abroad, he printed at Dublin, in 1686, his *Sciothericum Telescopium*, containing a Description of the Structure and Use of a Telescopic Dial, invented by him: another edition of which was published at London in 1700.

In 1688 the Philosophical Society of Dublin was broken up and dispersed by the confusion of the times.

MR.

Mr. Molyneux had diſtinguiſhed himſelf as a Member of it from the beginning, and preſented ſeveral diſcourſes upon curious ſubjects; ſome of which were tranſmitted to the Royal Society at London, and afterwards printed in the Philoſophical Tranſactions. In 1689, among great numbers of other Proteſtants, he withdrew from the diſturbances in Ireland, occaſioned by the ſeverities of Tyrconnel's government; and after a ſhort ſtay at London, he fixed himſelf with his family at Cheſter. In this retirement, he employed himſelf in putting together the materials he had ſome time before prepared for his *Dioptrics*, in which he was much aſſiſted by Mr. Flamſteed; and in Auguſt 1690, he went to London to put it to the preſs, where the ſheets were reviſed by Dr. Halley, who, at our author's requeſt, gave leave for printing, in the appendix, his celebrated Theorem for finding the Foci of Optic Glaſſes. Accordingly the book came out, 1692, in 4to, under the title of "*Dioptrica Nova*; a Treatiſe of Dioptrics, in two parts; wherein the various effects and appearances of ſpherical glaſſes, both convex and concave, ſingle and combined, in teleſcopes and microſcopes, together with their uſefulneſs in many concerns of human life, are explained." He gave it the title of *Dioptrica Nova*, both becauſe it was almoſt wholly new, very little being borrowed from other writers, and becauſe it was the firſt book that appeared in Engliſh upon the ſubject. The work contains ſeveral of the moſt generally uſeful propoſitions for practice, demonſtrated in a clear and eaſy manner, for which reaſon it was for many years uſed by the artificers: and the ſecond part is very entertaining, eſpecially in the hiſtory which he gives of the ſeveral optical inſtruments, and of the diſcoveries made by them.

Before he left Cheſter he loſt his lady, who died ſoon after ſhe had brought him a ſon. Illneſs had deprived her of her eye-ſight 12 years before, that is, ſoon after her marriage; from which time ſhe had been very ſickly, and afflicted with great pains in her head.

As ſoon as the public tranquillity was ſettled in his native country, he returned home; and, upon the convening of a new parliament in 1692, was choſen one of the repreſentatives for the city of Dublin. In the next parliament, in 1695, he was choſen to repreſent the univerſity there, and continued to do ſo to the end of his life; that learned body having lately conferred on him the degree of doctor of laws. He was likewiſe nominated by the lord-lieutenant one of the commiſſioners for the forfeited eſtates, to which employment was annexed a ſalary of 500l. a year; but looking upon it as an invidious office, he declined it.

In 1698, he publiſhed "The Caſe of Ireland ſtated, in regard to its being bound by Acts of Parliament made in England:" in which it is ſuppoſed he has delivered all, or moſt, that can be ſaid upon this ſubject, with great clearneſs and ſtrength of reaſoning.

Among many learned perſons with whom he maintained correſpondence and friendſhip, Mr. Locke was in a particular manner dear to him, as appears from their letters. In the above mentioned year, which was the laſt of our author's life, he made a journey to England, on purpoſe to pay a viſit to that great man; and not long after his return to Ireland, he was ſeized with a fit of the ſtone, which terminated his exiſtence.

Beſides the three works already mentioned, viz, the *Sciothericum Teleſcopium*, the *Dioptrica Nova*, and the *Caſe of Ireland ſtated*; he publiſhed a great number of pieces in the Philoſophical Tranſactions, which are contained in the volumes 14, 15, 16, 18, 19, 20, 21, 22, 23, 26, 29, ſeveral papers commonly in each volume.

MOLYNEUX (*Samuel*), ſon of the former, was born at Cheſter in July 1689; and educated with great care by his father, according to the plan laid down by Locke on that ſubject. When his father died, he fell under the management of his uncle, Dr. Thomas Molyneux, an excellent ſcholar and phyſician at Dublin, and alſo an intimate friend of Mr. Locke, who executed his truſt ſo well, that Mr. Molyneux became afterwards a moſt polite and accompliſhed gentleman, and was made ſecretary to George the 3d when prince of Wales. Aſtronomy and Optics being his favourite ſtudies, as they had been his father's, he projected many ſchemes for the advancement of them, and was particularly employed in the years 1723, 1724, and 1725, in perfecting the method of making teleſcopes; one of which inſtruments, of his own making, he had preſented to John the 5th, king of Portugal.

Being ſoon after appointed a commiſſioner of the admiralty, he became ſo engaged in public affairs, that he had not leiſure to purſue thoſe enquiries any farther, as he intended. He therefore gave his papers to Dr. Robert Smith, profeſſor of aſtronomy at Cambridge, whom he invited to make uſe of his houſe and apparatus of inſtruments, in order to finiſh what he had left imperfect. But Mr. Molyneux dying ſoon after, Dr. Smith loſt the opportunity; he however ſupplied what was wanting from M. Huygens and others, and publiſhed the whole in his "Complete Treatiſe of Optics."

MOMENT, in Time, is ſometimes taken for an extremely ſmall part of duration; but, more properly, it is only an inſtant or termination or limit in time, like a point in geometry. Maclaurin's Fluxions, vol. 1, pa. 245.

MOMENTS, in the new Doctrine of Infinites, denote the indefinitely ſmall parts of quantity; or they are the ſame with what are otherwiſe called infiniteſimals, and differences, or increments and decrements; being the momentary increments or decrements of quantity conſidered as in a continual flux.

Moments are the generative principles of magnitude: they have no determined magnitude of their own; but are only inceptive of magnitude.

Hence, as it is the ſame thing, if, inſtead of theſe Moments, the velocities of their increaſes and decreaſes be made uſe of, or the finite quantities that are proportional to ſuch velocities; the method of proceeding which conſiders the motions, changes, or fluxions of quantities, is denominated, by Sir Iſaac Newton, the Method of Fluxions.

Leibnitz, and moſt foreigners, conſidering theſe infinitely ſmall parts, or infiniteſimals, as the differences of two quantities; and thence endeavouring to find the differences of quantities, i. e. ſome Moments, or quantities indefinitely ſmall, which taken an infinite number of times ſhall equal given quantities; call theſe Moments

ments, Differences; and the method of procedure, the Differential Calculus.

MOMENT, or *Momentum*, in Mechanics, is the ſame thing with Impetus, or the quantity of motion in a moving body.

In comparing the motions of bodies, the ratio of their Momenta is always compounded of the quantity of matter and the celerity of the moving body: ſo that the momentum of any ſuch body, may be conſidered as the rectangle or product of the quantity of matter and the velocity of the motion. As, if *b* denote any body, or the quantity or maſs of matter, and *v* the velocity of its motion; then *bv* will expreſs, or be proportional to, its Momentum *m*. Alſo if B be another body, and V its velocity; then its Momentum M, is as BV. So that, in general, M : *m* :: BV : *bv*, i. e. the Momenta are as the products of the maſs and velocity. Hence, if the Momenta M and *m* be equal, then ſhall the two products BV and *bv* be equal alſo; and conſequently B : *b* :: *v* : V, or the bodies will be to each other in the inverſe or reciprocal ratio of their velocities; that is, either body is ſo much the greater as its velocity is leſs. And this force of Momentum is of a different kind from, and incomparably greater than, any mere dead weight, or preſſure, whatever.

The Momentum alſo of any moving body, may be conſidered as the aggregate or ſum of all the Momenta of the parts of that body; and therefore when the magnitudes and number of particles are the ſame, and alſo moved with the ſame celerity, then will the Momenta of the wholes be the ſame alſo.

MONADES. DIGITS.

MONOCEROS, the *Unicorn*, one of the new conſtellations of the northern hemiſphere, or one of thoſe which Hevelius has added to the 48 old aſteriſms, and formed out of the ſtellæ informes, or thoſe which were not comprized within the outlines of any of the others. In Hevelius's catalogue, the Unicorn contains 19 ſtars, but in the Britannic catalogue 31.

MONOCHORD, a muſical inſtrument with only one ſtring, uſed by the Ancients to try the variety and proportion of ſounds. It was formed of a rule, divided and ſubdivided into ſeveral parts, on which there is a moveable ſtring ſtretched over two bridges at the extremes of it. In the interval between theſe is a ſliding or moveable bridge, by means of which, in applying it to the different diviſions of the line, the ſounds are found to bear the ſame proportion to each other, as the diviſion of the line cut by the bridge. This inſtrument is alſo called the *harmonical canon*, or the *canonical rule*, becauſe it ſerves to meaſure the degrees of gravity or acuteneſs. Ptolomy examines his harmonical intervals by the Monochord. When the chord was divided into two equal parts, ſo that the parts were as 1 to 1, they called them *uniſons*; but if they were as 2 to 1, they called them *octaves* or *diapaſons*; when they were as 3 to 2, they called them *diapentes*, or *fifths*; if they were as 4 to 3, they called them *diateſſarons*, or *fourths*; if the parts were as 5 to 4, they called them *diton*, or *major-third*; but if they were as 6 to 5, they were called a *demi-diton*, or *minor-third*; and laſtly, if the parts were as 24 to 25, a *demitone*, or *dieze*.

The Monochord, being thus divided, was properly what they called a ſyſtem, of which there were many kinds, according to the different diviſions of the Monochord.

MONOCHORD is alſo uſed for any muſical inſtrument conſiſting of only one chord or ſtring. Such is the Trump-marine.

MONOMIAL, in Algebra, is a ſimple or ſingle nomial, conſiſting of only one term; as *a* or *ax*, or a^2bx^3, &c.

MONOTRIGLYPH, a term in Architecture, denoting the ſpace of one triglyph between two pilaſters, or two columns.

MONSOON, a regular or periodical wind, that blows one way for 6 months together, and the contrary way the other 6 months of the year. Theſe prevail in ſeveral parts of the eaſtern and ſouthern oceans.

MONTH, the 12th part of the year, and is ſo called from the Moon, by whoſe motions it was regulated; being properly the time in which the moon runs through the zodiac. The lunar Month is either *illuminative*, *periodical*, or *ſynodical*.

Illuminative MONTH, is the interval between the firſt appearance of one new moon and that of the next following. As the moon appears ſometimes ſooner after one change than after another, the quantity of the Illuminative Month is not always the ſame. The Turks and Arabs reckon by this Month.

Lunar Periodical MONTH, is the time in which the moon runs through the zodiac, or returns to the ſame point again; the quantity of which is 27days 7hrs 43m. 8ſec.

Lunar Synodical MONTH, called alſo a Lunation, is the time between two conjunctions of the moon with the ſun, or between two new moons; the quantity of which is 29 days, 12 hours, 44m. 3ſec. 11 thirds.

The ancient Romans uſed Lunar Months, and made them alternately of 29 and 30 days: They marked the days of each Month by three terms, viz, Calends, Nones, and Ides.

Solar MONTH, is the time in which the ſun runs through one entire ſign of the ecliptic, the mean quantity of which is 30 days 10 hours 29 min. 5 ſec. being the 12th part of 365 ds. 5 hrs. 49 min. the mean ſolar year.

Aſtronomical or *Natural* MONTH, is that meaſured by ſome exact interval correſponding to the motion of the ſun or moon. Such are the lunar and ſolar months above-mentioned.

Civil or *Common* MONTH, is an interval of a certain number of whole days, approaching nearly to the quantity of ſome aſtronomical month. Theſe may be either lunar or ſolar. The

Civil Lunar MONTH, conſiſts alternately of 29 and 30 days. Thus will two Civil Months be equal to aſtronomical ones, abating for the odd minutes; and ſo the new moon will be kept to the firſt day of ſuch Civil Months for a long time together. This was the Month in Civil or common uſe among the Jews, Greeks, and Romans, till the time of Julius Cæſar. The

Civil Solar MONTH, conſiſted alternately of 30 and 31 days, excepting one Month of the twelve, which conſiſted only of 29 days, but every 4th year of 30 days. And this form of Civil Months was introduced by Julius Cæſar. Under Auguſtus, the 6th Month, till

till then from its place called Sextilis, received the name Auguſtus, now Auguſt, in honour of that prince; and, to make the compliment ſtill the greater, a day was added to it; which made it conſiſt of 31 days, though till then it had only contained 30 days; to compenſate for which, a day was taken from February, making it conſiſt of 28 days, and 29 every 4th year. And ſuch are the Civil or Calendar Months now uſed through Europe.

MOON, *Luna*, ☾, one of the heavenly bodies, being a ſatellite, or ſecondary planet to the earth, conſidered as a primary planet, about which ſhe revolves in an elliptic orbit, or rather the earth and Moon revolve about a common centre of gravity, which is as much nearer to the earth's centre than to the Moon's, as the maſs of the former exceeds that of the latter.

The mean time of a revolution of the Moon about the earth, from one new moon to another, when ſhe overtakes the ſun again, is 29d. 12h. 44m. 3s. 11th.; but ſhe moves once round her own orbit in 27d. 7h. 43m. 8s. moving about 2290 miles every hour; and turns once round her axis exactly in the time that ſhe goes round the earth, which is the reaſon that ſhe ſhews always the ſame ſide towards us; and that her day and night taken together are juſt as long as our lunar month.

The mean diſtance of the Moon from the earth is $60\frac{1}{2}$ radii, or $30\frac{1}{4}$ diameters, of the earth; which is about 240,000 miles. The mean excentricity of her orbit is $\frac{5}{100}$, or $\frac{1}{18}$th nearly of her mean diſtance, amounting to about 13,000 miles.

The Moon's diameter is to that of the earth, as 20 to 73, or nearly as 3 to 11, or 1 to $3\frac{2}{3}$; and therefore it is equal to 2180 miles: her mean apparent diameter is $31' 16''\frac{1}{2}$, that of the ſun being $32' 12''$. The ſurface of the Moon is to the ſurface of the earth, as 1 to $13\frac{1}{4}$, or as 3 to 40; ſo that the earth reflects 13 times as much light upon the Moon, as ſhe does upon the earth; and the ſolid content to that of the earth. as 3 to 146, or as 1 to $48\frac{2}{3}$. The denſity of the Moon's body is to that of the earth, as 5 to 4; and therefore her quantity of matter to that of the earth, as 1 to 39 very nearly: the force of gravity on her ſurface, is to that on the earth, as 100 to 293. The Moon has little or no difference of ſeaſons; becauſe her axis is almoſt perpendicular to the ecliptic.

Phenomena and Phaſes of the MOON. The Moon being a dark, opaque, ſpherical body, only ſhining with the light ſhe receives from the ſun, hence only that half turned towards him, at any inſtant, can be illuminated, the oppoſite half remaining in its native darkneſs: then as the face of the Moon viſible on our earth, is that part of her body turned towards us; whence, according to the various poſitions of the Moon, with reſpect to the earth and ſun, we perceive different degrees of illumination; ſometimes a large and ſometimes a leſs portion of the enlightened ſurface being viſible: And hence the Moon appears ſometimes increaſing, then waning; ſometimes horned, then half round; ſometimes gibbous, then full and round. This may be eaſily illuſtrated by means of an ivory ball, which being before a candle in various poſitions, will preſent a greater or leſs portion of its illuminated hemiſphere to the view of the obſerver, according to its ſituation in moving it round the candle.

The ſame phaſes may be otherwiſe exhibited thus: Let S repreſent the ſun, T the earth, and ABCD &c the Moon's orbit. (Plate xv, fig. 3.) Now, when the Moon is at A, in conjunction with the ſun S, her dark ſide being entirely turned towards the earth, ſhe will be inviſible, as at *a*, and is then called the new Moon. When ſhe comes to her firſt octant at B, or has run through the 8th part of her orbit, a quarter of her enlightened hemiſphere will be turned towards the earth, and ſhe will then appear horned, as at *b*. When ſhe has run through the quarter of her orbit, and arrived at C, ſhe ſhews us the half of her enlightened hemiſphere, as at *c*, when it is ſaid ſhe is one half full. At D ſhe is in her 2d octant, and by ſhewing us more of her enlightened hemiſphere than at C, ſhe appears gibbous, as at *d*. At her oppoſition at E her whole enlightened ſide is turned towards the earth, when ſhe appears round, as at *e*, and ſhe is ſaid to be full; having increaſed all the way round from A to E. On the other ſide ſhe decreaſes again all the way from E to A: thus, in her 3d octant at F, part of her dark ſide being turned towards the earth, ſhe again appears gibbous, as at *f*. At G ſhe appears ſtill farther decreaſed, ſhewing again juſt one half of her illuminated ſide, as at *g*. But when ſhe comes to her 4th octant at H, ſhe preſents only a quarter of her enlightened hemiſphere, and ſhe again appears horned, as at *h*. And at A, having now completed her courſe, ſhe again diſappears, or becomes a new moon again, as at firſt. And the earth preſents all the very ſame phaſes to a ſpectator in the Moon, as ſhe does to us, but only in a contrary order, the one being full when the other changes, &c.

The Motions of the MOON are moſt of them very irregular, and very conſiderably ſo. The only equable motion ſhe has, is her revolution on her own axis, in the ſpace of a month, or time in which ſhe moves round the earth; which is the reaſon that ſhe always turns the ſame face towards us.

This expoſure of the ſame face is not ſo uniformly ſo however, but that ſhe turns ſometimes a little more of the one ſide, and ſometimes of the other, called the Moon's Libration; and alſo ſhews ſometimes a little more towards one pole, and ſometimes towards the other, by a motion like a kind of Wavering, or Vacillation. The former of theſe motions happens from this: the Moon's rotation on her axis is equable or uniform; while her motion in her orbit is unequal, being quickeſt when the Moon is in her perigee, and ſloweſt when in the apogee, like all other planetary motions; which cauſes that ſometimes more of one ſide is turned to the earth, and ſometimes of the other. And the other irregularity ariſes from this: that the axis of the Moon is not perpendicular, but a little inclined to the plane of her orbit: and as this axis maintains its parallelism, in the Moon's motion round the earth; it muſt neceſſarily change its ſituation, in reſpect of an obſerver on the earth; whence it happens that ſometimes the one, and ſometimes the other pole of the Moon becomes viſible.

The very orbit of the Moon is changeable, and does not always perſevere in the ſame figure: for though her orbit be elliptical, or nearly ſo, having the earth in one focus, the excentricity of the ellipſe is varied, being ſometimes increaſed, and ſometimes diminiſhed; viz,

being

being greateſt when the line of the apſes coincides with that of the ſyzygies, and leaſt when theſe lines are at right angles to each other.

Nor is the apogee of the Moon without an irregularity; being found to move forward, when it coincides with the line of the ſyzygies; and backward, when it cuts that line at right angles. Neither is this progreſs or regreſs uniform; for in the conjunction or oppoſition, it goes briſkly forward; and in the quadratures, it either moves ſlowly forward, ſtands ſtill, or goes backward.

The motion of the nodes is alſo variable; being quicker and ſlower in different poſitions.

The Phyſical Cauſe of the Moon's *Motion*, about the earth, is the ſame as that of all the primary planets about the ſun, and of the ſatellites about their primaries, viz, the mutual attraction between the earth and Moon.

As for the particular irregularities in the Moon's motion, to which the earth and other planets are not ſubject, they ariſe from the ſun which acts on, and diſturbs her in her ordinary courſe through her orbit; and are all mechanically deducible from the ſame great law by which her general motion is directed, viz, the law of gravitation and attraction. The other ſecondary planets, as thoſe of Jupiter, Saturn, &c, are alſo ſubject to the like irregularities with the Moon; as they are expoſed to the ſame perturbating or diſturbing force of the ſun; but their diſtance ſecures them from being ſo greatly affected as the Moon is, and alſo from being ſo well obſerved by us.

For a familar idea of this matter, it muſt firſt be conſidered, that if the ſun acted equally on the earth and Moon, and always in parallel lines, this action would ſerve only to reſtrain them in their annual motions round the ſun, and no way affect their actions on each other, or their motions about their common centre of gravity. But becauſe the Moon is nearer the ſun, in one half of her orbit, than the earth is, but farther off in the other half of her orbit; and becauſe the power of gravity is always leſs at a greater diſtance; it follows, that in one half of her orbit the Moon is more attracted than the earth towards the ſun, and leſs attracted, than the earth in the other half: and hence irregularities neceſſarily ariſe in the motions of the Moon; the exceſs of attraction in the firſt caſe, and the defect in the ſecond, becoming a force that diſturbs her motion: and beſides, the action of the ſun, on the earth and Moon, is not directed in parallel lines, but in lines that meet in the centre of the ſun; which makes the effect of the diſturbing force ſtill the more complex and embarraſſing. And hence, as well as from the various ſituations of the Moon, ariſe the numerous irregularities in her motions, and the equations, or corrections, employed in calculating her places, &c.

Newton, as well as others, has computed the quantities of theſe irregularities, from their cauſes. He finds that the force added to the gravity of the Moon in her quadratures, is to the gravity with which ſhe would revolve in a circle about the earth, at her preſent mean diſtance, if the ſun had no effect on her, as 1 to $178\frac{2}{40}$: he finds that the force ſubducted from her gravity in the conjunctions and oppoſitions, is double of this quantity; and that the area deſcribed in a given time in the quarters, is to the area deſcribed in the ſame time in the conjunctions and oppoſitions, as 10973 to 11073: and he finds that, in ſuch an orbit, her diſtance from the earth in her quarters, would be to her diſtance in the conjunctions and oppoſitions, as 70 to 69. Upon theſe irregularities, ſee Maclaurin's Account of Newton's Diſcoveries, book 4, chap. 4; as alſo moſt books of aſtronomy. Other particulars relating to the Moon's motions, &c, have been ſtated as follow: The power of the Moon's influence, as to the tides, is to that of the ſun, as $6\frac{1}{3}$ to 1, according to Sir I. Newton; but different according to others.

As to the figure of the Moon, ſuppoſing her at firſt to have been a fluid, like the ſea, Newton calculates, that the earth's attraction would raiſe the water there near 90 feet high, as the attraction of the Moon raiſes our ſea 12 feet: whence the figure of the Moon muſt be a ſpheroid, whoſe greateſt diameter extended, will paſs through the centre of the earth; and will be longer than the other diameter, perpendicular to it, by 180 feet; and hence it comes to paſs, that we always ſee the ſame face of the Moon; for ſhe cannot reſt in any other poſition, but always endeavours to conform herſelf to this ſituation: Princip. lib. 3, prop. 38.

Newton eſtimates the mean apparent diameter of the Moon at $32' 12''$; as the ſun is $31' 27''$.

The denſity of the Moon he concludes is to that of the earth, as 9 to 5 nearly; and that the maſs, or quantity of matter, in the Moon, is to that of the earth, as 1 to 26 nearly.

The plane of the Moon's orbit is inclined to that of the ecliptic, and makes with it an angle of about 5 degrees: but this inclination varies, being greateſt when ſhe is in the quarters, and leaſt when in her ſyzygies.

As to the inequality of the Moon's motion, ſhe moves ſwifter, and by the radius drawn from her to the earth deſcribes a greater area in proportion to the time, alſo has an orbit leſs curved, and by that means comes nearer to the earth, in her ſyzygies or conjunctions, than in the quadratures, unleſs the motion of her eccentricity hinders it: which eccentricity is the greateſt when the Moon's apogee falls in the conjunction, but leaſt when this falls in the quadratures: her motion is alſo ſwifter in the earth's aphelion, than in its perihelion. The apogee alſo goes forward ſwifter in the conjunction, and goes ſlower at the quadratures: but her nodes are at reſt in the conjunctions, and recede ſwifteſt of all in the quadratures.

The Moon alſo perpetually changes the figure of her orbit, or the ſpecies of the ellipſe ſhe moves in.

There are alſo ſome other inequalities in the motion of this planet, which it is very difficult to reduce to any certain rule: as the velocities or horary motions of the apogee and nodes, and their equations, with the difference between the greateſt eccentricity in the conjunctions, and the leaſt in the quadratures; and that inequality which is called the Variation of the Moon. All theſe do increaſe and decreaſe annually, in a triplicate ratio of the apparent diameter of the ſun: and this variation is increaſed and diminiſhed in a duplicate ratio of the time between the quadratures; as is proved by Newton in many parts of his Principia.

He

He alſo found that the apogees in the Moon's ſyzygies, go forward in reſpect of the fixed ſtars, at the rate of 23′ each day; and backwards in the quadratures 16′½ per day: and therefore the mean annual motions he eſtimates at 40 degrees.

The gravity of the Moon towards the earth, is increaſed by the action of the ſun, when the Moon is in the quadratures, and diminiſhed in the ſyzygies: and, from the ſyzygies to the quadrature, the gravity of the Moon towards the earth is continually increaſed, and ſhe is continually retarded in her motion: but from the quadrature to the ſyzygy, the Moon's motion is perpetually diminiſhed, and the motion in her orbit is accelerated.

The Moon is leſs diſtant from the earth at the ſyzygies, and more at the quadratures.

As radius is to ¾ of the ſine of double the Moon's diſtance from the ſyzygy, ſo is the addition of gravity in the quadratures, to the force which accelerates or retards the Moon in her orbit.

And as radius is to the ſum or difference of ½ the radius and ¾ the coſine of double the diſtance of the Moon from the ſyzygy, ſo is the addition of gravity in the quadratures, to the decreaſe or increaſe of the gravity of the Moon at that diſtance.

The apſes of the Moon go forward when ſhe is in the ſyzygies, and backward in the quadratures. But, in a whole revolution of the Moon, the progreſs exceeds the regreſs.

In a whole revolution, the apſes go forward the faſteſt of all when the line of the apſes is in the nodes; and in the ſame caſe they go back the ſloweſt of all in the ſame revolution.

When the line of the apſes is in the quadratures, the apſes are carried in conſequentia, the leaſt of all in the ſyzygies; but they return the ſwifteſt in the quadratures; and in this caſe the regreſs exceeds the progreſs, in one entire revolution of the Moon.

The eccentricity of the orbit undergoes various changes every revolution. It is the greateſt of all when the line of the apſes is in the ſyzygies, and the leaſt when that line is in the quadratures.

Conſidering one entire revolution of the Moon, cæteris paribus, the nodes move in antecedentia ſwifteſt of all when ſhe is in the ſyzygies; then ſlower and ſlower, till they are at reſt, when ſhe is in the quadratures.

The line of nodes acquires ſucceſſively all poſſible ſituations in reſpect of the ſun; and every year it goes twice through the ſyzygies, and twice through the quadratures.

In one whole revolution of the Moon, the nodes go back very faſt when they are in the quadratures; then ſlower till they come to reſt, when the line of nodes is in the ſyzygies.

The inclination of the plane of the orbit is changed by the ſame force with which the nodes are moved; being increaſed as the Moon recedes from the node, and diminiſhed as ſhe approaches it.

The inclination of the orbit is the leaſt of all when the nodes are come to the ſyzygies. For in the motion of the nodes from the ſyzygies to the quadratures, and in one entire revolution of the Moon, the force which increaſes the inclination exceeds that which diminiſhes it; therefore the inclination is increaſed; and it is the greateſt of all when the nodes are in the quadratures.

The Moon's motion being conſidered in general: her gravity towards the earth is diminiſhed coming near the ſun, and the periodical time is the greateſt; as alſo the diſtance of the Moon, cæteris paribus, the greateſt when the earth is in the perihelion.

All the errors in the Moon's motion are ſomething greater in the [illegible] than in the oppoſition.

All the diſturbing forces are inverſely as the cube of the diſtance of the ſun from the earth; which when it remains the ſame, they are as the diſtance of the Moon from the earth. Conſidering all the diſturbing forces together, the direction of gravity prevails.

The figure of the Moon's path, about the earth, is, as has been ſaid, [illegible] eclipſe; but her path, in moving, together with the earth about the ſun, is made up of a ſeries of [illegible] epicycloids, and is in every point concave towards the earth. See Maclaurin's Account of Newton's Philoſ. pa. 336, 4to. Ferguſon's Aſtron. pa. 1[illegible] and Rowe's Flux. pa. 225, edit. 2.

Aſtronomy of the Moon.

To determine the Periodical and Synodical Months; or the period of the Moon's revolution about the earth, and the period between one oppoſition or conjunction and another.

In the middle of a total eclipſe, the Moon is in oppoſition to the ſun: meaſure therefore the time between two ſuch eclipſes, at ſome conſiderable diſtance of time from each other, and divide this by the number of lunations that have paſſed in the mean time; ſo ſhall the quotient be the quantity of the ſynodical month. Compute alſo the ſun's mean motion during the time of this ſynodical month, which add to 360°. Then, as the ſum is to 360°, ſo is the ſynodical to the periodical month.

For example, Copernicus obſerved two eclipſes of the Moon, the one at Rome on November 6, 1500, at 12 at night, and the other at Cracow on Auguſt 1, 1523, at 4 h. 25 min. the difference of meridians being 0 h. 29 min.: hence the quantity of the ſynodical month is thus determined:

2d Obſerv.	[illegible]	237	4[h]	25[m]
1ſt Obſerv.	[illegible]	0	0	29
Difference	[illegible]	237	3	56
Add intercalary days		45		
Exact interval	[illegible]	282	3	56

which divided by 282, the number of lunations in that time, gives the ſynodical month 29[d] 12[h] 44[m].

From two other obſervations of eclipſes, the one at Cracow, the other at Babylon, the ſame author determines more accurately the quantity of the ſynodical month to be 29[d] 12[h] 43[m] 5[s]; and from other obſervations, probably more accurate ſtill, the ſame is fixed at 29[d] 12[h] 44[m].

The ſun's mean motion in that time 29° 0′ 34″ 18‴, added to 360°, gives the Moon's motion 389° 0′ 34″ 18‴; Therefore the periodical month is 27[d] 7[h] 43[m] 5[s].

According

According to the obſervations of Kepler,

the mean ſynodical month is	29d	12h	44m	3s	2th,
and the mean periodical month	27	7	43	8	

Hence, 1, the quantity of the periodical month being given, by the rule of three are found the Moon's diurnal or horary motion, &c: and thus may tables of the mean motion of the Moon be conſtructed.

2. If the mean diurnal motion of the ſun be ſubtracted from that of the Moon, the remainder will give the Moon's diurnal motion from the ſun: and thus may a table of this motion be conſtructed.

3. Since the Moon is in the node at the time of a total eclipſe, if the ſun's place be found for that time, and 6 ſigns be added to the ſame, the ſum will give the place of that node.

4. By comparing the ancient obſervations with the modern, it appears, that the nodes have a motion, and that they proceed in antecedentia, or backwards from Taurus to Aries, from Aries to Piſces, &c. Therefore if the diurnal motion of the nodes be added to the Moon's diurnal motion, the ſum will be the motion of the Moon from the node; and thence by the rule of three, may be found in what time the Moon goes 360° from the dragon's head, or aſcending node, or in what time ſhe goes from, and returns to it; that is, the quantity of the Dracontic Month.

5. If the motion of the apogee be ſubtracted from the mean motion of the Moon, the remainder will be the Moon's mean motion from the apogee; and hence, by the rule of three, the quantity of the Anomaliſtic Month is determined.

Thus, according to Kepler's obſervations,

The mean ſynodical month is	29d	12h	44m	3s 2th
The periodical month -	27	7	43	8
The place of the apogee for the year 1700 Jan. 1 old ſtyle, was	11s	8°	57′	1″
The place of the aſcending node	4	27	39	17
Mean diurnal motion of the Moon		13	10	35
Diurnal motion of the apogee			6	41
Diurnal motion of the nodes			3	11
Theref. diurnal mot. from the latter		13	13	46
And the diurnal motion from the apogee		13	3	54

Laſtly, the eccentricity is 4362, of ſuch parts as the ſemidiameter of the eccentric is 100,000.

To find nearly the Moon's *Age or Change.*

To the epact add the number and day of the month; their ſum, abating 30 if it be above, is the Moon's age; and her age taken from 30, ſhews the day of the change.

The numbers of the months, or monthly epacts, are the Moon's age at the beginning of each month, when the ſolar and lunar years begin together; and are thus:

0	2	1	2	3	4	5	6	8	8	10	10
Jan.	Feb.	Mar.	Ap.	Ma.	Jun.	Jul.	Aug.	Sep.	Oct.	Nov.	Dec.

For Ex. To find the Moon's age the 14th of Oct. 1783.

Here, the epact is	26
Number of the month	8
Day of the month	14
The ſum is	48
Subtract or abate	30
Leaves Moon's age	18
Taken from	30
Days till the change	12
Anſwering to Oct.	26

To find nearly the Moon's *Southing*, or coming to the Meridian.

Take $\frac{4}{5}$ or $\frac{8}{10}$ of her age, for her ſouthing nearly; after noon, if it be leſs than 12 hours; but if greater, the exceſs is the time after laſt midnight.

For Ex. Oct. 14, 1783;

The Moon's age is 18 days			
$\frac{8}{10}$ of which is 14·4 or	14h	24m	
Subtract -	12	00	
Rem. Moon's ſouthing	2	24	in the morning.

Mr. Ferguſon, in his Select Exerciſes, pa. 135 &c, has given very eaſy tables and rules for finding the new and full Moons near enough the truth for any common almanac. But the Nautical Almanac, which is now always publiſhed for ſeveral years before hand, in a great meaſure ſuperſedes the neceſſity of theſe and other ſuch contrivances.

Of the Spots and Mountains &c in the Moon.

The face of the Moon is greatly diverſified with inequalities, and parts of different colours, ſome brighter and ſome darker than the other parts of her diſc. When viewed through a teleſcope, her face is evidently diverſified with hills and valleys: and the ſame is alſo ſhewn by the edge or border of the Moon appearing jagged, when ſo viewed, eſpecially about the confines of the illuminated part when the Moon is either horned or gibbous.

The aſtronomers Florenti, Langreni, Hevelius, Grimaldi, Riccioli, Caſſini, and De la Hire, &c, have drawn the face of the Moon as viewed through teleſcopes; noting all the more ſhining parts, and, for the better diſtinction, marking them with ſome proper name; ſome of theſe authors calling them after the names of philoſophers, aſtronomers, and other eminent men; while others denominate them from the known names of the different countries, iſlands, and ſeas on the earth. The names adopted by Riccioli however are moſtly followed, as the names of Hipparchus, Tycho, Copernicus, &c. Fig. 4, plate xv, is a pretty exact repreſentation of the full Moon in her mean libration, with the numbers to the principal ſpots according to Riccioli, Caſſini, Mayer, &c, which denote the names as in the following Liſt of them: alſo the aſteriſk refers to one of the volcanoes obſerved by Herſchel.

*	Herſchel's Volcano	12	Helicon
1	Grimaldi	13	Capuanus
2	Galileo	14	Bulliald
3	Ariſtarchus	15	Eratoſthenes
4	Kepler	16	Timocharis
5	Gaſſendi	17	Plato
6	Schikard	18	Archimedes
7	Harpalus	19	Inſula Sinus Medii
8	Heraclides	20	Pitatus
9	Lanſberg	21	Tycho
10	Reinhold	22	Eudoxus
11	Copernicus	23	Ariſtotle

4 Manilius

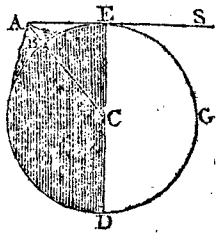
F Mare Serenitatis
G Mare Fœcunditatis
H Mare Criſium

That the ſpots in the Moon, which are taken for mountains and valleys, are really ſuch, is evident from their ſhadows. For in all ſituations of the Moon, the elevated parts are conſtantly found to caſt a triangular ſhadow in a direction from the ſun; and, on the contrary, the cavities are always dark on the ſide next the ſun, and illuminated on the oppoſite one; which is exactly conformable to what we obſerve of hills and valleys on the earth. And as the tops of theſe mountains are conſiderably elevated above the other parts of the ſurface; they are often illuminated when they are at a conſiderable diſtance from the confines of the enlightened hemiſphere, and by this means afford us a method of determining their heights.



Thus, let ED be the Moon's diameter, ECD the boundary of light and darkneſs; and A the top of a hill in the dark part beginning to be illuminated; with a teleſcope take the proportion of AE to the diameter ED: then there are given the two ſides AE, EC of a right-angled triangle ACE, the ſquares of which being added together give the ſquare of the third ſide AC, and the root extracted is that ſide itſelf; from which ſubtracting the radius BC, leaves AB the height of the mountain. In this way, Riccioli obſerved the top of the hill called St. Catherine, on the 4th day after the new moon, to be illuminated when it was diſtant from the confines of the enlightened hemiſphere about one 16th part of the Moon's diameter; and thence found its height muſt be near 9 miles.

It is probable however that this determination is too much. Indeed, Galileo makes AE to be only one 20th of ED, and Hevelius makes it only one 26th of ED; the former of theſe would give $5\frac{1}{2}$ miles, and the latter only $3\frac{3}{4}$ miles, for AB, the height of the mountain: and probably it ſhould be ſtill leſs than either of theſe.

Accordingly, they are greatly reduced by the obſervations of Herſchel, whoſe method of meaſuring them may be ſeen in the Philoſ. Tranſ. an. 1780, pa. 507. This gentleman meaſured the height of many of the lunar prominences, and draws at laſt the following concluſions:—"From theſe obſervations I believe it is evident, that the height of the lunar mountains in general is greatly over-rated; and that, when we have excepted a few, the generality do not exceed half a mile in their perpendicular elevation." And this is confirmed by the meaſurement of ſeveral mountains, as may be ſeen in the place above quoted.

As the Moon has on her ſurface mountains and valleys in common with the earth, ſome modern aſtronomers have diſcovered a ſtill greater ſimilarity, viz, that ſome of theſe are really volcanoes, emitting fire as thoſe on the earth do. An appearance of this kind was diſcovered ſome few years ago by Don Ulloa in an eclipſe of the ſun. It was a ſmall bright ſpot like a ſtar near the margin of the Moon, and which he at that time ſuppoſed to be a hole or valley with the ſun's light ſhining through it. Succeeding obſervations, however, have induced aſtronomers to attribute appearances of this kind to the eruption of volcanic fire; and Mr. Herſchel has particularly obſerved ſeveral eruptions of the lunar volcanos, the laſt of which he gives an account of in the Philoſ. Tranſ. for 1787. April 19, 10h. 36m. ſidereal time, I perceived, ſays he, three volcanos in different places of the dark part of the new Moon. Two of them are either already nearly extinct, or otherwiſe in a ſtate of going to break out; which perhaps may be decided next lunation. The third ſhews an actual eruption of fire or luminous matter: its light is much brighter than the nucleus of the comet which M. Mechain diſcovered at Paris the 10th of this month." The following night he found it burnt with greater violence; and by meaſurement he found that the ſhining or burning matter muſt be more than 3 miles in diameter; being of an irregular round figure, and very ſharply defined on the edges. The other two volcanos reſembled large faint nebulæ, that are gradually much brighter in the middle; but no well-defined luminous ſpot was diſcovered in them. He adds, "the appearance of what I have called the *actual fire*, or eruption of a volcano, exactly reſembled a ſmall piece of burning charcoal when it is covered by a very thin coat of white aſhes, which frequently adhere to it when it has been ſome time ignited; and it had a degree of brightneſs about as ſtrong as that with which a coal would be ſeen to glow in faint day-light.

It has been diſputed whether the Moon has any atmoſphere or not. The following arguments have been urged by thoſe who deny it.

1. The Moon, ſay they, conſtantly appears with the ſame brightneſs when our atmoſphere is clear; which could not be the caſe if ſhe were ſurrounded with an atmoſphere like ours, ſo variable in its denſity, and ſo often obſcured by clouds and vapours. 2. In an appulſe of the Moon to a ſtar, when ſhe comes ſo near it that a part of her atmoſphere comes between our eye and the ſtar, refraction would cauſe the latter to ſeem to change its place, ſo that the Moon would appear to touch it later than by her own motion ſhe would do. 3. Some philoſophers are of opinion, that becauſe there are no ſeas or lakes in the Moon, there is therefore no atmoſphere, as there is no water to be raiſed up in vapours.

But all theſe arguments have been anſwered by other aſtronomers in the following manner. It is denied that the Moon appears always with the ſame brightneſs, even when our atmoſphere appears equally clear. Hevelius relates, that he has ſeveral times found in

ſkies perfectly clear, when even ſtars of the 6th and 7th magnitude were viſible, that at the ſame altitude of the Moon with the ſame elongation from the ſun, and with the ſame teleſcope, the Moon and her maculæ do not appear equally lucid, clear, and conſpicuous at all times; but are much brighter and more diſtinct at ſome times than at others. And hence it is inferred that the cauſe of this phenomenon is neither in our air, in the tube, in the Moon, nor in the ſpectator's eye; but muſt be looked for in ſomething exiſting about the Moon. An additional argument is drawn from the different appearances of the Moon in total eclipſes, which it is ſuppoſed are owing to the different conſtitutions of the lunar atmoſphere.

To the 2d argument Dr. Long replies, that Newton has ſhewn (Princip. prop. 37, cor. 5), that the weight of any body upon the Moon is but a third part of what the weight of the ſame would be upon the earth: now the expanſion of the air is reciprocally as the weight that compreſſes it; therefore the air ſurrounding the Moon, being preſſed together by a weight of one-third, or being attracted towards the centre of the Moon by a force equal only to one-third of that which attracts our air towards the centre of the earth, it thence follows, that the lunar atmoſphere is only one-third as denſe as that of the earth, which is too little to produce any ſenſible refraction of the ſtar's light. Other aſtronomers have contended, that ſuch refraction was ſometimes very apparent. Mr. Caſſini ſays, that he often obſerved that Saturn, Jupiter, and the fixed ſtars, had their circular figures changed into an elliptical one, when they approached either to the Moon's dark or illuminated limb, though they own that, in other occultations, no ſuch change could be obſerved. And, with regard to the fixed ſtars, it has been urged that, granting the Moon to have an atmoſphere of the ſame nature and quantity as ours, no ſuch effect as a gradual diminution of light ought to take place; at leaſt none that we could be capable of perceiving. At the height of 44 miles, our atmoſphere is ſo rare as to be incapable of refracting the rays of light: this height is the 180th part of the earth's diameter; but ſince clouds are never obſerved higher than 4 miles, it appears that the vapourous or obſcure part is only the 1980th part. The mean apparent diameter of the Moon is 31′ 29″, or 1889″: therefore the obſcure parts of her atmoſphere, when viewed from the earth, muſt ſubtend an angle of leſs than one ſecond; which ſpace is paſſed over by the Moon in leſs than two ſeconds of time. It can therefore hardly be expected that obſervation ſhould generally determine whether the ſuppoſed obſcuration takes place or not.

As to the 3d argument, it concludes nothing, becauſe it is not known that there is no water in the Moon; nor, though this could be proved, would it follow that the lunar atmoſphere anſwers no other purpoſe than the raiſing of water into vapour. There is however a ſtrong argument in favour of the exiſtence of a lunar atmoſphere, taken from the appearance of a luminous circle round the Moon, in the time of total ſolar eclipſes; a circumſtance that has been obſerved by many aſtronomers; eſpecially in the total eclipſe of the ſun which happened May 1, 1706.

Of the Harveſt Moon. It is remarkable that the Moon, during the week in which ſhe is full about the time of harveſt, riſes ſooner after ſun-ſetting, than ſhe does in any other full-moon week in the year. By this means ſhe affords an immediate ſupply of light after ſun-ſet, which is very beneficial for the harveſt and gathering in the fruits of the earth: and hence this full Moon is diſtinguiſhed from all the others in the year, by calling it the Harveſt-Moon.

To conceive the reaſon of this phenomenon; it may firſt be conſidered, that the Moon is always oppoſite to the ſun when ſhe is full; that ſhe is full in the ſigns Piſces and Aries in our harveſt months, thoſe being the ſigns oppoſite to Virgo and Libra, the ſigns occupied by the ſun about the ſame ſeaſon; and becauſe thoſe parts of the ecliptic riſe in a ſhorter ſpace of time than others, as may eaſily be ſhewn and illuſtrated by the celeſtial globe: conſequently, when the Moon is about her full in harveſt, ſhe riſes with leſs difference of time, or more immediately after ſun-ſet, than when ſhe is full at other ſeaſons of the year.

In our winter, the Moon is in Piſces and Aries about the time of her firſt quarter, when ſhe riſes about noon; but her riſing is not then noticed, becauſe the ſun is above the horizon.

In ſpring, the Moon is in Piſces and Aries about the time of her change; at which time, as ſhe gives no light, and riſes with the ſun, her riſing cannot be perceived.

In ſummer, the Moon is in Piſces and Aries about the time of her laſt quarter; and then, as ſhe is on the decreaſe, and riſes not till midnight, her riſing uſually paſſes unobſerved.

But in autumn, the Moon is in Piſces and Aries at the time of her full, and riſes ſoon after ſun-ſet for ſeveral evenings ſucceſſively; which makes her regular riſing very conſpicuous at that time of the year.

And this would always be the caſe, if the Moon's orbit lay in the plane of the ecliptic. But as her orbit makes an angle of 5° 18′ with the ecliptic, and croſſes it only in the two oppoſite points called the nodes, her riſing when in Piſces and Aries will ſometimes not differ above 1 h. and 40 min. through the whole of 7 days; and at other times, in the ſame two ſigns ſhe will differ 3 hours and a half in the time of her riſing in a week, according to the different poſitions of the nodes with reſpect to theſe ſigns; which poſitions are conſtantly changing, becauſe the nodes go backward through the whole ecliptic in 18 years 225 days.

This revolution of the nodes will cauſe the Harveſt Moons to go through a whole courſe of the moſt and leaſt beneficial ſtates, with reſpect to the harveſt, every 19 years. The following Table ſhews in what years the Harveſt Moons are leaſt beneficial as to the times of their riſing, and in what years they are moſt beneficial, from the year 1790 to 1861; the column of years under the letter L, are thoſe in which the Harveſt-Moons are leaſt of all beneficial, becauſe they fall about the deſcending node; and thoſe under the letter M are the moſt of all beneficial, becauſe they fall about the aſcending node.

Harveſt Moons.

As to the Influence of the MOON, on the changes of the weather, and the conſtitution of the human body, it may be obſerved, that the vulgar doctrine concerning it is very ancient, and has alſo gained much credit among the Learned, though perhaps without ſufficient examination. The common opinion is, that the Lunar Influence is chiefly exerted about the time of the full and change, but more eſpecially the latter; and it would ſeem that long experience has in ſome degree eſtabliſhed the fact: hence, perſons obſerved at thoſe times to be a little deranged in their intellects, are called Lunatics; and hence many perſons anxiouſly look for the new Moon to bring a change in the weather. The Moon's Influence on the ſea, in producing tides, being agreed upon on all hands, it is argued that ſhe muſt alſo produce ſimilar changes in the atmoſphere, but in a much higher degree; which changes and commotions there, muſt, it is inferred, have a conſiderable influence on the weather, and on the human body.

Beſide the obſervations of the Ancients, which tend to eſtabliſh this doctrine, ſeveral among the Modern Philoſophers have defended the ſame opinion, and that upon the ſtrength of experience and obſervation; while others as ſtrenuouſly deny the fact. The celebrated Dr. Mead was a believer in the Influence of the Sun and Moon on the human body, and publiſhed a book to this purpoſe, intitled, De Imperio Solis ac Lunæ in Corpore Humano. The exiſtence of ſuch influence is however oppoſed by Dr. Horſley, the preſent biſhop of Rocheſter, in a learned paper upon this ſubject in the Philoſ. Tranſ. for the year 1775; where he gives a ſpecimen of arranging tables of meteorological obſervations, ſo as to deduce from them facts, that may either confirm or refute this popular opinion; recommending it to the Learned, to collect a large ſeries of ſuch obſervations, as no concluſions can be drawn from one or two only. On the other hand profeſſor Toaldo, and ſome French philoſophers, take the oppoſite ſide of the queſtion; and, from the authority of a long ſeries of obſervations, pronounce decidedly in favour of the Lunar Influence.

MOORE (Sir JONAS), a very reſpectable mathematician, Fellow of the Royal Society, and Surveyor-general of the Ordnance, was born at Whitby in Yorkſhire about the year 1620. After enjoying the advantages of a liberal education, he bent his ſtudies principally to the mathematics, to which he had always a ſtrong inclination. In the expeditions of King Charles the 1ſt into the northern parts of England, our author was introduced to him, as a perſon ſtudious and learned in thoſe ſciences; when the king expreſſed much approbation of him, and promiſed him encouragement; which indeed laid the foundation of his fortune. He was afterwards appointed mathematical maſter to the king's ſecond ſon James, to inſtruct him in arithmetic, geography, the uſe of the globes, &c. During Cromwell's government it ſeems he followed the profeſſion of a public teacher of mathematics; for I find him ſtyled, in the title-page of ſome of his publications, "profeſſor of the mathematics." After the return of Charles the 2d, he found great favour and promotion, becoming at length ſurveyor-general of the king's ordnance. He was it ſeems a great favourite both with the king and the duke of York, who often conſulted him, and were adviſed by him upon many occaſions. And it muſt be owned that he often employed his intereſt with the court to the advancement of learning and the encouragement of merit. Thus, he got Flamſteed houſe built in 1675, as a public obſervatory, recommending Mr. Flamſteed to be the king's aſtronomer, to make the obſervations there: and being ſurveyor-general of the ordnance himſelf, this was the reaſon why the ſalary of the aſtronomer royal was made payable out of the office of ordnance. Being a governor of Chriſt's hoſpital, it ſeems that by his intereſt the king founded the mathematical ſchool there, allowing a handſome ſalary for a maſter to inſtruct a certain number of the boys in mathematics and navigation, to qualify them for the ſea ſervice. Here he ſoon found an opportunity of exerting his abilities in a manner ſomewhat anſwerable to his wiſhes, namely, that of ſerving the riſing generation. And conſidering with himſelf the benefit the nation might receive from a mathematical ſchool, if rightly conducted, he made it his utmoſt care to promote the improvement of it. The ſchool was ſettled; but there ſtill wanted a methodical inſtitution from which the youths might receive ſuch neceſſary helps as their ſtudies required: a laborious work, from which his other great and aſſiduous employments might very well have exempted him, had not a predominant regard to a more general uſefulneſs engaged him to devote all the leiſure hours of his declining years to the improvement of ſo uſeful and important a ſeminary of learning.

Having thus engaged himſelf in the proſecution of this general deſign, he next ſketched out the plan of a courſe or ſyſtem of mathematics for the uſe of the ſchool, and then drew up and printed ſeveral parts of it himſelf, when death put an end to his labours, before the work was completed. I have not found in what year this happened; but it muſt have been but little before 1681, the year in which the work was publiſhed by his ſons-in-law, Mr. Hanway and Mr. Potinger. Of this work, the Arithmetic, Practical Geometry, Trigonometry, and Coſmography, were written by Sir Jonas himſelf, and printed before his death. The Algebra, Navigation, and the books of Euclid were ſupplied by Mr. Perkins, the then maſter of the mathematical ſchool. And the Aſtronomy, or Doctrine of the Sphere, was written by Mr. Flamſteed, the aſtronomer royal.

The

The liſt of Sir Jonas's works, as far as I have ſeen them, are the following:

1. The New Syſtem of Mathematics; above mentioned, in 2 vols 4to, 1681.

2. Arithmetic in two books, viz, Vulgar Arithmetic and Algebra. To which are added two Treatiſes, the one A new Contemplation Geometrical, upon the Oval Figure called the Ellipſis; the other, The two firſt books of Mydorgius, his Conical Sections analized &c. 8vo, 1660.

3. A Mathematical Compendium; or Uſeful Practices in Arithmetic, Geometry, and Aſtronomy, Geography and Navigation, &c, &c. 12mo, 4th edition in 1705.

4. A General Treatiſe of Artillery: or, Great Ordnance. Written in Italian by Tomaſo Moretii of Breſcia. Tranſlated into Engliſh, with notes thereupon, and ſome additions out of French for Sea-Gunners. By Sir Jonas Moore, Kt. 8vo, 1683.

MORTALITY. *Bills of Mortality*, are accounts or regiſters ſpecifying the numbers born, and buried, and ſometimes married, in any town, pariſh, or diſtrict. Theſe are of great uſe, not only in the doctrine of Life Annuities, but in ſhewing the degrees of healthineſs and prolificneſs, with the progreſs of population in the places where they are kept. It is therefore much to be wiſhed that ſuch accounts had always been correctly kept in every kingdom, and regularly publiſhed at the end of every year. We ſhould then have had under inſpection the comparative ſtrength of every kingdom, as far as it depends on the number of inhabitants, and its increaſe or decreaſe at different periods.

Such accounts are rendered ſtill more uſeful, when they include the ages of the dead, and the diſtempers of which they have died. In this caſe they convey ſome of the moſt important inſtructions, by furniſhing the means of aſcertaining the law which governs the waſte of human life, the values of annuities dependent on the continuance of any lives, or any ſurvivorſhips between them, and the favourableneſs or unfavourableneſs of different ſituations to the duration of human life.

There are but few regiſters of this kind; nor has this ſubject, though ſo intereſting to mankind, ever engaged much attention till lately. Indeed, bills of Mortality for the ſeveral pariſhes of the city of London have been kept from the year 1592, with little interruption; and a very ample account of them has been publiſhed down to the year 1759, by Dr. Birch, in a large 4to vol. which is perhaps the fulleſt work of the kind extant; containing beſides the bills of Mortality, with the diſeaſes and caſualties, ſeveral other valuable tracts on the ſubject of them, and on political arithmetic, by ſeveral other authors, as Capt. John Graunt, F. R. S.; Sir William Petty, F. R. S.; Corbyn Morris, Eſq. F. R. S.; and J. P. Eſq. F. R. S.; the whole forming a valuable repoſitory of materials; and it would be well if a continuation were publiſhed down to the preſent time, and ſo continued from time to time.

Bills containing the ages of the dead, were long ſince publiſhed for the town of Breſlaw in Sileſia. It is well known what uſe has been made of theſe by Dr. Halley, and after him by Mr. De Moivre. A table of the probabilities of the duration of human life at every age, deduced from them by Dr. Halley, was publiſhed in the Philoſ. Tranſ. vol. 17, and has been inſerted in this work under the article LIFE-*Annuities*; which is the firſt table of this kind that has been publiſhed. Since the publication of this table, ſimilar bills have been eſtabliſhed in many other places, in England, Germany, Switzerland, France, Holland, &c, but moſt eſpecially in Sweden; the reſults of ſome of which may be ſeen in the large comparative table of the duration of life, under the article LIFE-*Annuities*, in this work.

MORTAR, or MORTAR-PIECE, a ſhort piece of ordnance, thick and wide, proper for throwing bomb-ſhells, carcaſes, ſtones, grape-ſhot, &c.

It is thought that the uſe of Mortars is older than that of cannon: for they were employed in the wars of Italy, to throw balls of red-hot iron, and ſtones, long before the invention of ſhells: and it is generally believed that the Germans were the firſt inventors. The practice of throwing red-hot balls out of Mortars, was firſt practiſed at the ſiege of Stralſund in 1675, by the elector of Brandenburg; though ſome ſay, in 1653, at the ſiege of Bremen.

Mortars are made either of braſs or iron, and it is uſual to diſtinguiſh them by the diameter of the bore; as, the 13 inch, the 10 inch, or the 8 inch Mortar: there are ſome of a ſmaller ſort, as Coehorns of 4·6 inches, and Royals of 5·8 inches in diameter. As to the larger ſizes, as 18 inches, &c, they are now diſuſed by the Engliſh, as well as moſt other European nations. For the circumſtances relating to Mortars, ſee Muller's Artillery.

Coehorn MORTAR, a ſmall kind of one, invented by the celebrated engineer baron Coehorn, to throw ſmall ſhells or grenades. Theſe Mortars are often fixed, to the number of a dozen, on a block of oak, at the elevation of 45°.

MOTION, or *Local* MOTION, is a continued and ſucceſſive change of place. Borelli defines it, the ſucceſſive paſſage of a body from one place to another, in a determinate time, by becoming ſucceſſively contiguous to all the parts of the intermediate ſpace.

Motion is conſidered as of various kinds; as Natural, Violent, Abſolute and Relative, &c, &c.

Natural MOTION, is that which has its principle, or actuating force, within the moving body. Such is that of a ſtone falling towards the earth. And

Violent MOTION, is that whoſe principle is without, and againſt which the moving body makes a reſiſtance. Such is that of a ſtone thrown upwards, or of a ball ſhot off from a gun, &c.

Motion is again divided into Abſolute and Relative.

Abſolute MOTION, is the change of abſolute place, in any moving body, conſidered independently of any other motion; whoſe celerity therefore will be meaſured by the quantity of abſolute ſpace which the moveable body runs through. And

Relative MOTION, is the change of the relative place of a moving body, or conſidered with reſpect to the motion of ſome other body; and has its celerity eſtimated by the quantity of relative ſpace run through.

As to the Continuation of MOTION, or the cauſe why a body once in Motion comes to perſevere in it: this has

been much controverted among phyſical writers; and yet it follows very evidently from one of the grand Laws of Nature; viz, that all bodies perſevere in their preſent ſtate, whether of reſt or motion, unleſs diſturbed by ſome foreign powers. Motion therefore, once begun, would be continued in infinitum, were it to meet with no interruption from external cauſes; as the power of gravity, the reſiſtance of the medium, &c.

Nor has the communication of motion, or how a moving body comes to affect another at reſt, or how much of its motion is communicated by the firſt to the laſt, been leſs diſputed. See the Laws of it under the word PERCUSSION.

Motion is the proper ſubject of mechanics; and mechanics is the baſis of all natural philoſophy; which hence becomes denominated Mechanical.

In effect, all the phenomena of nature, all the changes that happen in the ſyſtem of bodies, are owing to Motion; and are directed according to the laws of it. Hence the modern philoſophers have applied themſelves with peculiar ardour to conſider the doctrine of Motion; to inveſtigate the properties and laws of it; by obſervation and experiment, joined to the uſe of geometry. And to this is owing the great advantage of the modern philoſophy above that of the Ancients; who were extremely diſregardful of the effects of Motion.

Among all the Ancients, there is nothing extant on Motion, excepting ſome things in Archimedes's books, De Æquiponderantibus. To Galileo is owing a great part of the doctrine of Motion: he firſt diſcovered the general laws of it, and particularly of the deſcent of heavy bodies, both perpendicularly and on inclined planes; the laws of the Motion of projectiles; the vibration of pendulums, and of ſtretched cords, with the theory of reſiſtances, &c: things which the Ancients had little notion of.

Torricelli poliſhed and improved the diſcoveries of his maſter, Galileo; and added many experiments concerning the force of percuſſion, and the equilibrium of fluids. Huygens improved very conſiderably on the doctrine of the pendulum; and both he and Borelli on the force of percuſſion. Laſtly, Newton, Leibnitz, Varignon, Mariotte, &c, have brought the doctrine of Motion ſtill much nearer to perfection.

The general laws of Motion were firſt brought into a ſyſtem, and analytically demonſtrated together, by Dr. Wallis, Sir Chriſtopher Wren, and M. Huygens, all much about the ſame time; the firſt in bodies not elaſtic, and the two latter in elaſtic bodies. Laſtly, the whole doctrine of Motion, including all the diſcoveries both of the Ancients and Moderns on that head, was given by Dr. Wallis in his Mechanica, ſive De Motu, publiſhed in 1670.

Quantity of MOTION, is the ſame as MOMENTUM, which ſee. It is a principle maintained by the Carteſians, and ſome others, that the Creator at the beginning impreſſed a certain Quantity of Motion on bodies; and that under ſuch laws, as that no part of it ſhould be loſt, but the ſame portion of Motion ſhould be conſtantly preſerved in matter: and hence they conclude, that if any moving body ſtrike another body, the former loſes no more of its Motion than it communicates to the latter. This poſition however has been oppoſed by other philoſophers, and perhaps juſtly, unleſs the preſervation of Motion be underſtood only of the quantity of it as eſtimated always in the ſame direction; for then it ſeems the principle will hold good. However, the reaſoning ought to have proceeded in the contrary order; by firſt obſerving from experiment, or otherwiſe, that when two bodies act upon each other, the one gains exactly the Motion which is loſt by the other, in the ſame direction; and from hence made the inference, that there is therefore the ſame Quantity of Motion preſerved in the univerſe, as was created by God in the beginning; ſince no body can act upon another, without being itſelf equally acted upon in the oppoſite or contrary direction.

The Continuation of MOTION, or the cauſe why a body once in Motion comes to perſevere in it, has been much controverted among phyſical writers; and yet it follows very evidently from one of the grand Laws of Nature; viz, that all bodies perſevere in their preſent ſtate, whether of Motion or reſt, unleſs they are diſturbed by ſome foreign powers. Motion, therefore, once begun, would be continued for ever, were it to meet with no interruption from external cauſes; as the power of gravity, the reſiſtance of the medium, &c.

The Communication of MOTION, or the manner in which a moving body comes to affect another at reſt, or how much of its Motion is communicated by the firſt to the laſt, has alſo been the ſubject of much diſcuſſion and controverſy. See the Laws of it under the word PERCUSSION.

MOTION may be conſidered either as Equable, and Uniform; or as Accelerated, and Retarded. Equable Motion, again, may be conſidered either as Simple, or as Compound; and Compound Motion either as Rectilinear, or as Curvilinear.

And all theſe again may be conſidered either with regard to themſelves, or with regard to the manner of their production, and communication, by percuſſion, &c.

Equable MOTION, is that by which the moving body proceeds with exactly the ſame velocity or celerity; paſſing always over equal ſpaces in equal times.

The Laws of Uniform Motion, are theſe: 1. The ſpaces deſcribed, or paſſed over, are in the compound ratio of the velocities, and the times of deſcribing thoſe ſpaces. So that, if V and v be any two uniform velocities, S and s the ſpaces deſcribed or paſſed over by them, in the reſpective times T and t:

then is $S : s :: TV : tv$,

or $20 : 12 :: 4 \times 5 : 3 \times 4$;

taking $T = 4$, $t = 3$, $V = 5$, and $v = 4$.

2. In Uniform Motions, the time is as the ſpace directly, and as the velocity reciprocally; or as the ſpace divided by the velocity. So that

$$T : t :: \frac{S}{V} : \frac{s}{v} \text{ or } :: Sv : sV.$$

3. The velocity is as the ſpace directly, and the time reciprocally; or as the ſpace divided by the time. That is,

$$V : v :: \frac{S}{T} : \frac{s}{t} \text{ or } :: St : sT.$$

Accelerated MOTION, is that which continually receives freſh acceſſions of velocity. And it is ſaid to be uniformly

uniformly accelerated, when its acceſſions of velocity are equal in equal times; ſuch as that which is produced by the continual action of one and the ſame force, like the force of gravity, &c.

Retarded MOTION, is that whoſe velocity continually decreaſes. And it is ſaid to be uniformly Retarded, when its decreaſe is continually proportional to the time, or by equal quantities in equal times; like that which is produced by the continual oppoſition of one and the ſame force; ſuch as the force of gravity, in uniformly retarding the Motion of a body that is thrown upwards.

The Laws of Motion, uniformly accelerated or retarded, are theſe:

1. In uniformly varied motions, the ſpace, S or s, is as the ſquare of the time, or as the ſquare of the greateſt velocity, or as the rectangle or product of the time and velocity.

That is, $S : s :: T^2 : t^2 :: V^2 : v^2 :: TV : tv$.

2. The velocity is the time, or as the ſpace divided by the time, or as the ſquare root of the ſpace.

That is, $V : v :: T : t :: \frac{S}{T} : \frac{s}{t} :: \sqrt{S} : \sqrt{s}$.

3. The time is as the velocity, or as the ſpace divided by the velocity, or as the ſquare root of the ſpace.

That is, $T : t :: V : v :: \frac{S}{V} : \frac{s}{v} :: \sqrt{S} : \sqrt{s}$.

4. When a ſpace is deſcribed, or paſſed over, by an uniformly varied Motion, the velocity either beginning at nothing, and continually accelerated; or elſe beginning at ſome determinate velocity, and continually retarded till the velocity be reduced to nothing; then the ſpace, ſo run over by the variable Motion, will be exactly equal to half the ſpace that would be run over in the ſame time by the greateſt velocity if uniformly continued for that time. So, for inſtance, if g denote the ſpace run over in one ſecond, or any other time, by ſuch a variable Motion; then $2g$ would be the ſpace that would be run over in one ſecond, or the ſame time, by the greateſt velocity uniformly continued for the ſame time; or $2g$ would be the greateſt velocity per ſecond which the moving body had. Conſequently, if t be any other time, s the ſpace run over in that time, and v the greateſt velocity attained in it; then, from the foregoing articles, it will be

$1'' : t'' :: 2g : 2gt = v$ the velocity,
and $1^2 : t^2 :: g : gt^2 = s$ the ſpace.

And hence, for any ſuch uniformly varied Motions, the relations among the ſeveral quantities concerned, will be expreſſed by the following equations: viz,

$$s = gt^2 = \tfrac{1}{2}tv = \frac{v^2}{4g},$$

$$v = 2gt = \frac{2s}{t} = 2\sqrt{gs},$$

$$t = \frac{v}{2g} = \frac{2s}{v} = \sqrt{\frac{s}{g}},$$

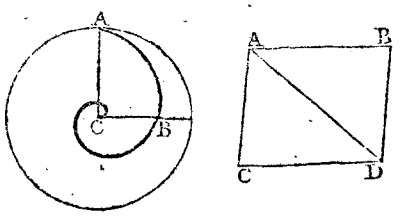
$$g = \frac{v}{2t} = \frac{s}{t^2} = \frac{v^2}{4s}.$$

And theſe equations will hold good in the Motion either generated or deſtroyed by the force of gravity, or by any other uniform force whatever. See alſo the articles GRAVITY, ACCELERATION, RETARDATION, &c. Again,

Simple MOTION, is that which is produced by ſome one power or force only, and is always rectilinear, or in one direction, whether the force be only momentary or continued. And

Compound MOTION, is that which is produced by two or more powers acting in different directions. See COMPOUND, and COMPOSITION *of Motion*.

If a moving body be acted on by a double power; the one according to the direction AB, the other according to AC; with the Compound Motion, or that which is compounded of theſe two together, it will deſcribe the diagonal AD of the parallelogram, whoſe ſides AB and AC it would have deſcribed in the ſame time with each of the reſpective powers apart.



And if the radius of a circle be carried round upon the centre C, while a point in the radius ſets off from A, and keeps moving along the radius towards the centre; then, by this Compound Motion, the path of the point will be a kind of a ſpiral ABC.

For the Particular Laws of MOTION, *ariſing from the Colliſion of bodies, both Elaſtic and Non-elaſtic, and that where the directions are both Perpendicular and Oblique*, ſee PERCUSSION.

For CIRCULAR *Motion*, and *the Laws of* PROJECTILES, ſee the reſpective words.

For the Motion of Pendulums, and the Laws of Oſcillation, ſee PENDULUM.

Perpetual MOTION, is a Motion which is ſupplied and renewed from itſelf, without the intervention of any external cauſe.

The celebrated problem of a Perpetual Motion, conſiſts in the inventing a machine, which has the principle of its Motion within itſelf; and is a problem that has employed the mathematicians for 2000 years; though none perhaps have proſecuted it with attention and earneſtneſs equal to thoſe of the preſent age. Infinite are the ſchemes, deſigns, plans, engines, wheels, &c, to which this long-deſired Perpetual Motion has given birth.

But M. De la Hire has proved the impoſſibility of any ſuch machine, and finds that it amounts to this; viz, to find a body which is both heavier and lighter at the ſame time; or to find a body which is heavier than itſelf. Indeed there ſeems but little in nature to countenance all this aſſiduity and expectation: among all the laws of matter and Motion, we know of none yet that ſeem likely to furniſh any principle or foundation for ſuch an effect.

Action and reaction it is allowed are always equal; and a body that gives any quantity of Motion to another, always loſes juſt ſo much of its own; but under the preſent ſtate of things, the reſiſtance of the air, the friction of the parts of machines, &c, do neceſſarily retard every Motion.

To continue the Motion therefore either, firſt, there muſt be a ſupply from ſome foreign cauſe; which in a Perpetual Motion is excluded.

Or, 2dly, all reſiſtance from the friction of the parts of matter muſt be removed; which neceſſarily implies a change in the nature of things.

Or, 3dly and laſtly, there muſt be ſome method of gaining a force equivalent to what is loſt, by the artful diſpoſition and combination of mechanic powers; to which laſt point then all endeavours are to be directed: but how, or by what means, ſuch force ſhould be gained, is ſtill a myſtery.

The multiplication of powers or forces, it is certain, avails nothing; for what is gained in power is loſt in time, ſo that the quantity of Motion ſtill remains the ſame. This is an inviolable law of nature; by which nothing is left to art, but the choice of the ſeveral combinations that may produce the ſame effect.

There are various ways by which abſolute force may be gained; but ſince there is always an equal gain in oppoſite directions, and no increaſe obtained in the ſame direction; in the circle of actions neceſſary to make a perpetual movement, this gain muſt be preſently loſt, and will not ſerve for the neceſſary expence of force employed in overcoming friction, and the reſiſtance of the medium. And therefore, though it could be ſhewn, that in an infinite number of bodies, or in an infinite machine, there could be a gain of force for ever, and a Motion continued to infinity, it does not follow that a perpetual movement can be made. That which was propoſed by M. Leibnitz in the Leipſic Acts of 1690, as a conſequence of the common eſtimation of the forces of bodies in Motion, is of this kind, and for this and other reaſons ought to be rejected. See PERPETUAL *Motion*; alſo ORFFYREUS's *Wheel*, &c.

Animal MOTION, is that by which the ſituation, figure, magnitude, &c, of the parts and members of animals are changed. Under theſe Motions, come all the animal functions; as reſpiration, circulation of the blood, excretion, walking, running, &c.

Animal Motions are uſually divided into two ſpecies; viz, Natural and Spontaneous.

Natural MOTION, is that involuntary one which is effected without the command of the will, by the mere mechaniſm of the parts. Such as the Motion of the heart and pulſe; the Periſtaltic Motion of the inteſtines, &c. But

Spontaneous, or *Muſcular* MOTION, is that which is performed by means of the muſcles, at the command of the will; which is hence called Voluntary Motion. Borelli has a celebrated treatiſe on this ſubject, entitled De Motu Animalium.

Inteſtine MOTION, denotes an agitation of the particles of which a body conſiſts.—Some philoſophers will have every body, and every particle of a body, in continual Motion. As for fluids, it is the definition they give of them, that their parts are in continual Motion. And as to ſolids, they infer the like Motion from the effluvia continually emitted through their pores. Hence Inteſtine Motion is repreſented to be a Motion of the internal and ſmaller parts of matter, continually excited by ſome external, latent agent, which of itſelf is inſenſible, and only diſcovers itſelf by its effects; appointed by Nature to be the great inſtrument of the changes in bodies.

MOTION, in Aſtronomy, is peculiarly applied to the orderly courſes of the heavenly bodies.

Mean MOTION. See MEAN.

The Motions of the celeſtial luminaries are of two kinds: Diurnal, or Common; and Secondary, or Proper.

Diurnal, or *Primary* MOTION, is that with which all the heavenly bodies, and the whole mundane ſphere, appear to revolve every day round the earth, from eaſt to weſt. This is alſo called the Motion of the Primum Mobile, and the Common Motion, to diſtinguiſh it from that rotation which is peculiar to each planet, &c.

Secondary, or *Proper* MOTION, is that with which a ſtar, planet, or the like, advances a certain ſpace every day from the weſt towards the eaſt. See the ſeveral Motions of each luminary, with the irregularities, &c, of them, under the proper articles, EARTH, MOON, STAR, &c.

Angular MOTION, is that by which the angular poſition of any thing varies. See ANGULAR.

Horary MOTION, is the Motion during each hour. See HORARY.

Paracentric MOTION *of Impetus*. See PARACENTRIC.

MOTION *of Trepidation*, &c. See TREPIDATION and LIBRATION.

MOTIVE *Power* or *Force*, is the whole power or force acting upon any body, or quantity of matter, to move it; and is proportional to the momentum or quantity of motion it can produce in a given time. To diſtinguiſh it from the Accelerative force, which is conſidered as affecting the celerity only.

MOTRIX, ſomething that has the power or faculty of moving. See *Vis Motrix*, and MOTION.

MOVEABLE, ſomething ſuſceptible of motion, or that is diſpoſed to be moved. A ſphere is the moſt Moveable of all bodies, or is the eaſieſt to be moved on a plane. A door is Moveable on its hinges; the magnetic needle on a pin or pivot, &c. Moveable is often uſed in contradiſtinction to Fixed or Fixt.

MOVEABLE *Feaſts*, are ſuch as are not always held on the ſame day of the year or month; though they may be on the ſame day of the week. Thus, Eaſter is a Moveable Feaſt; being always held on the Sunday which falls upon or next after the firſt full moon following the 21ſt of March. See Philoſ. Tranſ. numb. 240, pa. 185. All the other Moveable Feaſts follow Eaſter, keeping their conſtant diſtance from it; ſo that they are fixed with reſpect to it, though Moveable through the courſe of the year. Such are Septuageſima, Sexageſima, Aſh-Wedneſday, Aſcenſion-Day, Pentecoſt, Trinity-Sunday, &c.

MOVEMENT, a term often uſed in the ſame ſenſe with Automaton. The moſt uſual Movements for keeping time, are Clocks and Watches: the latter are ſuch as ſhew the parts of time by inſpection, and are portable in the pocket; the former ſuch as publiſh it by ſounds, and are fixed as furniture.

MOVEMENT, in its popular uſe, ſignifies all the inner works of a clock, watch, or other machine, that move, and by that motion carry on the deſign of the inſtrument. The Movement of a clock, or watch, is the inſide; or that part which meaſures the time, and ſtrikes, &c; excluſive of the frame, caſe, dial-plate, &c.

The parts common to both of theſe Movements are, the Main-ſpring with its appurtenances, lying in the ſpring box, and in the middle of it lapping about the ſpring-arbor, to which one end of it is faſtened. A-top of the ſpring-arbor is the Endleſs ſcrew, and its wheel; but in ſpring clocks this is a ratchet-wheel with its click, that ſtops it. That which the main-ſpring draws, and round which the chain or ſtring is wrapped, is called the fuſee: this is moſtly taper; in large works, going with weights, it is cylindrical, and is called the barrel. The ſmall teeth at the bottom of the fuſee or barrel, which ſtop it in winding up, is called the Ratchet; and that which ſtops it when wound up, and is for that end driven up by the ſpring, the Gardegut. The Wheels are various: the parts of a wheel are, the Hoop or Rim; the Teeth, the Croſs, and the Collet, or piece of braſs ſoldered on the arbor or ſpindle on which the wheel is riveted. The little wheels, playing in the teeth of the larger, are called Pinions; and their teeth, which are 4, 5, 6, 8, &c, are called Leves; the ends of the ſpindle are called Pivots; and the guttured wheel, with iron ſpikes at bottom, in which the line of common clocks runs, the Pulley.

Theory of Calculating the Numbers for MOVEMENTS.

1. It is firſt to be obſerved, that a wheel, divided by its pinion, ſhews how many turns the pinion has to one turn of the wheel.

2. That from the fuſee to the balance the wheels drive the pinions, conſequently the pinions run faſter, or make more revolutions, than the wheel; but it is the contrary from the great wheel to the dial-wheel.

3. That the wheels and pinions are written down either as vulgar fractions, or in the way of diviſion in common arithmetic: for example, a wheel of 60, moving a pinion of 5, is ſet down either thus $\frac{60}{5}$, or thus 5)60, which is better. And the number of turns the pinion has in one turn of the wheel, as a quotient, thus 5) 60 (12. A whole Movement may be written as follows:

$$\begin{array}{rrl} 4) & 36 & (9 \\ \hline 5) & 55 & (11 \\ 5) & 45 & (9 \\ 5) & 40 & (8 \\ \hline & & 17 \end{array}$$

where the uppermoſt number expreſſes the pinion of report 4, the dial-wheel 36, and the turns of the pinion 9; the ſecond, the pinion and great wheel; the third, the ſecond wheel &c; the fourth, the contrate wheel; and the laſt, 17, the crown-wheel.

4. Hence, from the number of turns any pinion makes, in one turn of the wheel it works in, may be determined the number of turns a wheel or pinion has at any greater diſtance, viz, by multiplying the quotients together; the product being the number of turns. Thus, ſuppoſe the wheels and pinions as in the caſe above; the quotient 11 multiplied by 9, gives 99, the number of turns in the ſecond pinion 5 to one turn of the wheel 55, which runs concentrical, or on the ſame ſpindle, with the pinion 5. Again, 99 multiplied by 8, gives 792, the number of turns the laſt pinion has to one turn of the firſt wheel 5. Hence we proceed to find, not only the turns, but the number of beats of the balance, in the time of thoſe turns. For, having found the number of turns the crown-wheel has in one turn of the wheel propoſed, thoſe turns multiplied by its notches, give half the number of beats in that one turn of the wheel. Suppoſe, for example, the crown-wheel to have 720 turns, to one of the firſt wheel; this number multiplied by 15, the notches in the crown-wheel, produces 10800, half the number of ſtrokes of the balance in one turn of the firſt wheel of 80 teeth.

The general diviſion of a Movement is, into the clock, and watch parts.

MOULDINGS, in Architecture, are certain projections beyond the naked of a wall, column, wainſcot &c, the aſſemblage of which forms cornices, door-caſes, and other decorations of architecture.

MOULDINGS, are annexed to great guns by way of ornament, and perhaps in ſome parts for ſtrength; and probably are derived from the hoops or rings which bound the long iron bars together, anciently uſed in making cannon.

MOYNEAU. See MOINEAU.

MULLER (JOHN), commonly called REGIOMONTANUS, from Mons Regius, or Koningſberg, a town in Franconia, where he was born in 1436, and became the greateſt aſtronomer and mathematician of his time. He was indeed a very prodigy for genius and learning. Having firſt acquired grammatical learning in his own country, he was admitted, while yet a boy, into the academy at Leipſic, where he formed a ſtrong attachment to the mathematical ſciences, arithmetic, geometry, aſtronomy, &c. But not finding proper aſſiſtance in theſe ſtudies at this place, he removed, at only 15 years of age, to Vienna, to ſtudy under the famous Purbach, the profeſſor there, who read lectures in thoſe ſciences with the higheſt reputation. A ſtrong and affectionate friendſhip ſoon took place between theſe two, and our author made ſuch rapid improvement in the ſciences, that he was able to be aſſiſting to his maſter, and to become his companion in all his labours. In this manner they ſpent about ten years together; elucidating obſcurities, obſerving the motions of the heavenly bodies, and comparing and correcting the tables of them; particularly thoſe of Mars, which they found to diſagree with the motions, ſometimes as much as two degrees.

About this time there arrived at Vienna the cardinal Beſſarion, who came to negociate ſome affairs for the pope; who, being a lover of aſtronomy, ſoon formed an acquaintance with Purbach and Regiomontanus. He had begun to form a Latin Verſion of Ptolomy's Almageſt, or an Epitome of it; but not having time to go on with it himſelf, he requeſted Purbach to complete the work, and for that purpoſe to return with him into Italy, to make himſelf maſter of the Greek tongue, which he was as yet unacquainted with. To theſe propoſals Purbach only aſſented, on condition that Regiomontanus would accompany him, and ſhare in all the labours. They firſt however, by

means of an Arabic Verſion of Ptolomy, made ſome progreſs in the work; but this was ſoon interrupted by the death of Purbach, which happened in 1461, in the 39th year of his age. The whole taſk then devolved upon Regiomontanus, who finiſhed the work, at the requeſt of Purbach, made to him when on his death-bed. This work our author afterwards reviſed and perfected at Rome, when he had learned the Greek language, and conſulted the commentator Theon, &c.

Regiomontanus accompanied the cardinal Beſſarion in his return to Rome, being then near 30 years of age. Here he applied himſelf diligently to the ſtudy of the Greek language; not neglecting however to make aſtronomical obſervations and compoſe various works in that ſcience; as his Dialogue againſt the Theories of Cremonenſis. The cardinal going to Greece ſoon after, Regiomontanus went to Ferrara, where he continued the ſtudy of the Greek language under Theodore Gaza; who explained to him the text of Ptolomy, with the commentaries of Theon; till at length he became ſo perfect in it, that he could compoſe verſes, and read it like a critic.—In 1463 he went to Padua, where he became a member of the univerſity; and, at the requeſt of the ſtudents, explained Alfraganus, an Arabian philoſopher.—In 1464 he removed to Venice, to meet and attend his patron Beſſarion. Here he wrote, with great accuracy, his Treatiſe of Triangles, and a Refutation of the Quadrature of the Circle, which Cardinal Cuſan pretended he had demonſtrated. The ſame year he returned with Beſſarion to Rome; where he made ſome ſtay, to procure the moſt curious books: thoſe he could not purchaſe, he took the pains to tranſcribe, for he wrote with great facility and elegance; and others he got copied at a great expence. For as he was certain that none of theſe books could be had in Germany, he thought on his return thither, he would at his leiſure tranſlate and publiſh ſome of the beſt of them. During this time too he had a fierce conteſt with George Trabezonde, whom he had greatly offended by animadverting on ſome paſſages in his tranſlation of Theon's Commentary.

Being now weary of rambling about, and having procured a great number of manuſcripts, which was one great object of his travels, he returned to Vienna, and performed for ſome time the offices of his profeſſorſhip, by reading of lectures &c. After being a while thus employed, he went to Buda, on the invitation of Matthias king of Hungary, who was a great lover of letters and the ſciences, and had founded a rich and noble library there: for he had bought up all the Greek books that could be found on the ſacking of Conſtantinople; alſo thoſe that were brought from Athens, or wherever elſe they could be met with through the whole Turkiſh dominions, collecting them all together into a library at Buda. But a war breaking out in this country, he looked out for ſome other place to ſettle in, where he might purſue his ſtudies, and for this purpoſe he retired to Noremberg. He tells us, that the reaſons which induced him to deſire to reſide in this city the remainder of his life were, that the artiſts there were dextrous in fabricating his aſtronomical machines; and beſides, he could from thence eaſily tranſmit his letters by the merchants into foreign countries. Being now well verſed in all parts of learning, and made the utmoſt proficiency in mathematics, he determined to occupy himſelf in publiſhing the beſt of the ancient authors, as well as his own lucubrations. For this purpoſe he ſet up a printing-houſe, and formed a nomenclature of the books he intended to publiſh, which ſtill remains.

Here that excellent man, Bernard Walther, one of the principal citizens, who was well ſkilled in the ſciences, eſpecially aſtronomy, cultivated an intimacy with Regiomontanus; and as ſoon as he underſtood thoſe laudable deſigns of his, he took upon himſelf the expence of conſtructing the aſtronomical inſtruments, and of erecting a printing-houſe. And firſt he ordered aſtronomical rules to be made of tin, for obſerving the altitudes of the ſun, moon and planets. He next conſtructed a rectangular, or aſtronomical radius, for taking the diſtances of thoſe luminaries. Then an armillary aſtrolabe, ſuch as was uſed by Ptolomy and Hipparchus, for obſerving the places and motions of the ſtars. Laſtly, he made other ſmaller inſtruments, as the torquet, and Ptolomy's meteoroſcope, with ſome others which had more of curioſity than utility in them. From this apparatus it evidently appears, that Regiomontanus was a moſt diligent obſerver of the laws and motions of the celeſtial bodies, if there were not ſtill ſtronger evidences of it in the accounts of the obſervations themſelves which he made with them.

With regard to the printing-houſe, which was the other part of his deſign in ſettling at Noremberg, as ſoon as he had completed it, he put to preſs two works of his own, and two others. The latter were, The *New Theories* of his maſter Purbach, and the *Aſtronomicon* of Manilius. And his own were, the *New Calendar*, in which were given (as he ſays in the Index of the books which he intended to publiſh) the true conjunctions and oppoſitions of the luminaries, their eclipſes, their true places every day, &c. His other work was his *Ephemerides*, of which he thus ſpeaks in the ſaid index: "The Ephemerides, which they vulgarly call an Almanac, for 30 years: where you may every day ſee the true motion of all the planets, of the moon's nodes, with the aſpects of the moon to the ſun and planets, the eclipſes of the luminaries; and in the fronts of the pages are marked the latitudes." He publiſhed alſo moſt acute commentaries on Ptolomy's Almageſt: a work which cardinal Beſſarion ſo highly valued, that he ſcrupled not to eſteem it worth a whole province. He prepared alſo new verſions of Ptolomy's Coſmography; and at his leiſure hours examined and explained works of another nature. He enquired how high the vapours are carried above the earth, which he fixed to be not more than 12 German miles. He ſet down obſervations of two comets that appeared in the years 1471 and 1472.

In 1474, pope Sixtus the 4th conceived a deſign of reforming the calendar; and ſent for Regiomontanus to Rome, as the propereſt and ableſt perſon to accompliſh his purpoſe. Regiomontanus was very unwilling to interrupt the ſtudies, and printing of books, he was engaged in at Noremberg; but receiving great promiſes from the pope, who alſo for the preſent named him biſhop of Ratiſbon, he at length conſented to go. He arrived at Rome in 1475, but died there the year after, at only 40 years of age; not without a

ſuſpicion of being poiſoned by the ſons of George Trabezonde, in revenge for the death of their father, which was ſaid to have been cauſed by the grief he felt on account of the criticiſms made by Regiomontanus on his tranſlation of Ptolomy's Almageſt.

Purbach firſt of any reduced the trigonometrical tables of ſines, from the old ſexageſimal diviſion of the radius, to the decimal ſcale. He ſuppoſed the radius to be divided into 600000 equal parts, and computed the ſines of the arcs to every ten minutes, in ſuch equal parts of the radius, by the decimal notation. This project of Purbach was perfected by Regiomontanus; who not only extended the ſines to every minute, the radius being 600000, as deſigned by Purbach, but afterwards, diſliking that ſcheme, as evidently imperfect, he computed them likewiſe to the radius 1000000, for every minute of the quadrant. Regiomontanus alſo introduced the tangents into trigonometry, the canon of which he called *fœcundus*, becauſe of the many great advantages ariſing from them. Beſide theſe things, he enriched trigonometry with many theorems and precepts. Indeed, excepting for the uſe of logarithms, the trigonometry of Regiomontanus is but little inferior to that of our own time. His Treatiſe, on both Plane and Spherical Trigonometry, is in 5 books; it was written about the year 1464, and printed in folio at Noremberg in 1533. In the 5th book are various problems concerning rectilinear triangles, ſome of which are reſolved by means of algebra: a proof that this ſcience was not wholly unknown in Europe before the treatiſe of Lucas de Burgo.

Regiomontanus was author of ſome other works beſide thoſe before mentioned. Peter Ramus, in the account he gives of the admirable works attempted and performed by Regiomontanus, tells us, that in his workſhop at Noremberg there was an automaton in perpetual motion: that he made an artificial fly, which taking its flight from his hand, would fly round the room, and at laſt, as if weary, would return to his maſter's hand: that he fabricated an eagle, which, on the emperor's approach to the city, he ſent out, high in the air, a great way to meet him, and that it kept him company to the gates of the city. Let us no more wonder, adds Ramus, at the dove of Arebytas, ſince Noremberg can ſhew a fly, and an eagle, armed with geometrical wings. Nor are thoſe famous artificers, who were formerly in Greece, and Egypt, any longer of ſuch account, ſince Noremberg can boaſt of her Regiomontanuſes. For Wernerus firſt, and then the Schoneri, father and ſon, afterwards, revived the ſpirit of Regiomontanus.

MULTANGULAR FIGURE, is one that has many angles, and conſequently many ſides alſo. Theſe are otherwiſe called polygons.

MULTILATERAL FIGURES, are ſuch as have many ſides, or more than four ſides.

MULTINOMIAL, or MULTINOMIAL *Roots*, are ſuch as are compoſed of many names, parts, or members; as, $a + b + c + d$ &c.

For the raiſing an infinite Multinomial to any propoſed power, or extracting any root out of ſuch power, ſee a method by Mr. De Moivre, in the Philoſ. Tranſ. numb. 230. See alſo POLYNOMIAL.

MULTIPLE, MULTIPLEX, a number which comprehends ſome other number ſeveral times. Thus, 6 is a Multiple of 2, this being contained in 6 juſt 3 times. Alſo 12 is a common Multiple of 6, 4, and 3; comprehending the firſt twice, the ſecond thrice, and the third four times.

MULTIPLE *Ratio* or *Proportion*, is that which is between Multiple numbers &c. If the leſs term of a ratio be an aliquot part of the greater, the ratio of the greater to the leſs is called Multiple; and that of the leſs to the greater Submultiple.

A Submultiple number, is that which is contained in the Multiple. Thus, the numbers 2, 3, and 4 are Submultiples of 12 and 24.

Duple, triple, &c ratios; as alſo ſubduples, ſubtriples, &c, are ſo many ſpecies of Multiple and Submultiple ratios.

MULTIPLE *Superparticular Proportion*, is when one number or quantity contains another more than once, and a certain aliquot part; as 10 to 3, or $3\frac{1}{3}$ to 1.

MULTIPLE *Superpartient Proportion*, is when one number or quantity contains another ſeveral times, and ſome parts beſides; as 29 to 6, or $4\frac{5}{6}$ to 1.

MULTIPLICAND, is one of the two factors in the rule of multiplication, being that number given to be multiplied by the other, called the multiplicator, or multiplier.

MULTIPLICATION, is, in general, the taking or repeating of one number or quantity, called the Multiplicand, as often as there are units in another number, called the Multiplier, or Multiplicator; and the number or quantity reſulting from the Multiplication, is called the Product of the two foregoing numbers or factors.

Multiplication is a compendious addition; performing at once, what in the uſual way of addition would require many operations: for the multiplicand is only added to itſelf, or repeated, as often as is expreſſed by the units in the multiplier. Thus, if 6 were to be multiplied by 5, the product is 30, which is the ſum ariſing from the addition of the number 6 five times to itſelf.

In every Multiplication, 1 is in proportion to the multiplier, as the multiplicand is to the product.

Multiplication is of various kinds, in whole numbers, in fractions, decimals, algebra, &c.

1. MULTIPLICATION *of Whole Numbers*, is performed by the following rules: When the multiplier conſiſts of only one figure, ſet it under the firſt, or right-hand figure, of the multiplicand; then, drawing a line underneath, and beginning at the ſaid firſt figure, multiply every figure of the multiplicand by the multiplier; ſetting down the ſeveral products below the line, proceeding orderly from right to left. But if any of theſe products amount to 10, or ſeveral 10's, either with or without ſome overplus, then ſet down only the overplus, or ſet down 0 if there be no overplus; and carry, to the next product, as many units as the former contained of tens. Thus, to multiply 35092 by 4.

Multiplicand	35092
Multiplier	4
Product	140368

When

When the multiplier conſiſts of ſeveral figures; multiply the multiplicand by each figure of it, as before, and place the ſeveral lines of products underneath each other in ſuch order, that the firſt figure or cipher of each line may fall ſtraight under its reſpective multiplier, or multiplying figure; then add theſe ſeveral lines of products together, as they ſtand, and the ſum of them all will be the product of the whole multiplication. Thus, to multiply 63017 by 236:

Multiplicand - -	63017
Multiplier - -	236
Product of 63017 by 6 -	378102
Product of 63017 by 30	189051
Product of 63017 by 200	126034
Whole product	14872012

The ſeveral lines of products may be ſet down in any order, or any of them firſt, and any other of them ſecond, &c; for the order of placing them can make no difference in the ſum total. There are many abbreviations, and peculiar caſes, according to circumſtances, which may be ſeen in moſt books of arithmetic.

The mark or character now uſed for Multiplication, is either the × croſs or a ſingle point · ; the former being introduced by Oughtred, and the latter I think by Leibnitz.

To Prove MULTIPLICATION. This may be done various ways; either by dividing the product by the multiplier, then the quotient will be equal to the multiplicand; or divide the ſame product by the multiplicand, and the quotient will come out equal to the multiplier; or in general divide the product by either of the two factors, and the quotient will come out equal to the other factor, when the operations are all right. But the more uſual, and compendious way of proving Multiplication, is by what is called caſting out the nines; which is thus performed: Add the figures of the multiplicand all together, and as often as the ſum amounts to 9, reject it always, and ſet down the laſt overplus as in the margin; this in the foregoing example is 8. Then do the ſame by the multiplier, ſetting down the laſt overplus, which is 2, on the right of the former remainder 8. Next multiply theſe two remainders, 2 and 8, together, and from their product 16, caſt out the 9, and there remains 7, which ſet down over the two former. Laſtly, add up, in the ſame manner, all the figures of the whole product of the multiplication, viz 14872012, caſting out the 9's, and then there remains 7, to be ſet down under the two firſt remains. Then when the figure at top, is the ſame as that at bottom, as they are here both 7's, the work it may be preſumed is right; but if theſe two figures ſhould not be the ſame, it is certainly wrong.

2. *To Multiply Money, or any other thing, conſiſting of different Denominations together, by any number, uſually called Compound Multiplication.* Beginning at the loweſt, multiply the number of each denomination ſeparately by the multiplier, ſetting down the products below them. But if any of theſe products amount to as much as 1 or more of the next higher denominations, carry ſo many to the next product, and ſet down only the overplus. *For Ex.* To find the amount of 9 *things at* 11 12s 4½d. *each; or to multiply* 11 12s 4½d *by* 9: *ſet the multiplier* 9 *under the given ſum as in the margin, and multiply thus:* 9 *halfpence make* 4*d halfpenny, ſet down* ½ penny, and carry 4; then 9 times 4 are 36, and 4 to carry make 40 pence, which are 3s and 4d, ſet down 4 and carry 3; next 9 times 12 are 108, and 3 to carry, make 111 ſhillings, or 5l 11s, ſet down 11, and carry 5; laſtly 9 times 1 are 9, and 5 to carry, make 14, which ſet down; and then the whole amount, or product, comes to 141 11s 4½d.

l	s	d.
1	12	4½
		9
14	11	4½

3. *To Multiply Vulgar Fractions.*—Multiply all the given numerators together for the numerator of the product, and all the denominators together for the denominator of the product ſought.

Thus, $\frac{2}{3}$ multiplied by $\frac{4}{5}$, or $\frac{2}{3} \times \frac{4}{5}$ make $\frac{8}{15}$.

And $\frac{3}{5} \times \frac{2}{5} \times \frac{3}{7}$ make $\frac{18}{175}$.

And here it may be noted that, when there are any common numbers in the numerators and denominators, theſe may be omitted from both, which will make the operation ſhorter, and bring out the whole product in a fraction much ſimpler and in lower terms. Thus,

$\frac{2}{3} \times \frac{3}{4} \times \frac{5}{6}$, by leaving out the two 3's, become $\frac{2 \times 5}{4 \times 6} = \frac{10}{24}$ or $\frac{5}{12}$

Alſo, when any numerators and denominators will both abbreviate or divide by one and the ſame number, let them be divided, and the quotients uſed inſtead of them. So, in the above example, after omitting the two 3's, let the 2 and 6 be both divided by 2, and uſe the quotients 1 and 3 inſtead of them, ſo ſhall the expreſſion become $\frac{1 \times 5}{4 \times 3} = \frac{5}{12}$, as before.

4. *To Multiply Decimals.*—Multiply the given numbers together the ſame as if they were whole numbers, and point off as many decimals in the whole product as there are in both factors together; as in the annexed example, where the number of decimals is five, becauſe there are three in the multiplicand, and two in the multiplier.—When it happens that there are not ſo many figures in the product as there muſt be decimals, then prefix as many ciphers as will ſupply the defect.

	13830
	18440
	2305
	4610
	50·38730

5. *Croſs* MULTIPLICATION, otherwiſe called *Duodecimal Arithmetic*, is the multiplying of numbers together whoſe ſubdiviſions proceed by 12's; as feet, inches, and parts, that is 12th parts, &c; a thing of very frequent uſe in ſquaring, or multiplying toge-

ther the dimenſions of the works of bricklayers, carpenters, and other artificers. *For Example.* To multiply 5 feet 3 inches by 2 feet 4 inches. Set them down as in the margin, and multiply all the parts of the multiplicand by each part of the multiplier; thus, 2 times 3 make 6 inches, and 2 times 5 make 10 feet; then 4 times 3 make 12 parts, or 1 inch to carry; and 4 times 5 make 20, and 1 to carry makes 21 inches, or 1f. 9inc. to ſet down below the former line: Laſtly adding the two lines together, the whole ſum or product amounts to 12f. 3inc.

12	3

6. MULTIPLICATION *in Algebra.* This is performed, 1. When the quantities are ſimple, by only joining the letters together like a word; and if the ſimple quantities have any coefficients or numbers joined with them, multiply the numbers together, and prefix the product of them to the letters ſo joined together. But, in algebra, we have not only to attend to the quantities themſelves, but alſo to the ſigns of them; and the general rule for the ſigns is this: When the ſigns are alike, or the ſame, either both + or both −, then the ſign of the product will always be +; but when the ſigns are different, or unlike, the one +, and the other −, then the ſign of the product will be −. Hence theſe

EXAMPLES.

Mult.	$+a$	$-2a$	$+6x$	$-8x$	$-3ab$
By	$+b$	$-4b$	$-3a$	$+5a$	$-5ac$
Products	$+ab$	$+8ab$	$-18av$	$-40ax$	$+15a^2bc$

2. In Compound quantities, multiply every term or part of the multiplicand by each term ſeparately of the multiplier, and ſet down all the products with their ſigns, collecting always into one ſum as many terms as are ſimilar or like to one another.

EXAMPLES.

$a + b$	$a - b$	$a + b$
$a + b$	$a - b$	$a - b$
$a^2 + ab$	$a^2 - ab$	$a^2 + ab$
$+ ab + b^2$	$- ab + b^2$	$- ab - b^2$
$a^2 + 2ab + b^2$	$a^2 - 2ab + b^2$	$a^2 \quad - b^2$
$2a - 3b$	$2a + 4x$	$a^2 - ax$
$4a + 5b$	$2a - 4x$	$2a + 2x$
$8a^2 - 12ab$	$4a^2 + 8ax$	$2a^3 - 2a^2x$
$+ 10ab - 15b^2$	$- 8ax - 16x^2$	$+ 2a^2x - 2ax^2$
$8a^2 - 2ab - 15b^2$	$4a^2 \quad - 16x^2$	$2a^3 \quad - 2ax^2$

3. In Surd quantities, if the terms can be reduced to a common ſurd, the quantities under each may be multiplied together, and the mark of the ſame ſurd prefixed to the product; but if not, then the different ſurds may be ſet down with ſome mark of multiplication between them, to denote their product.

EXAMPLES.

$7\sqrt{ax}$	$\sqrt{7}$	$\sqrt[3]{7ab}$	$\sqrt{12a}$	$6a\sqrt{2cx}$
$5\sqrt{cx}$	$\sqrt{5}$	$\sqrt[3]{4ac}$	$\sqrt{3a}$	$2b\sqrt{3ax}$
$35\sqrt{acx^2}$	$\sqrt{35}$	$\sqrt[3]{28a^2bc}$	$\sqrt{36a^2} = 6a$	$12ab\sqrt{6acx^2}$

4. Powers or Roots of the ſame quantity are multiplied together, by adding their exponents.

Thus, $a^2 \times a^3 = a^5$; and $\overline{a+x}^3 \times \overline{a+x}^5 = \overline{a+x}^8$: alſo $x^2 \times x^{\frac{1}{2}} = x^{\frac{5}{2}}$; and $a^{\frac{1}{2}} \times a^{\frac{1}{2}} = a^1$ or a.

To Multiply Numbers together by Logarithms.—This is performed by adding together the logarithms of the given numbers, and taking the number anſwering to that ſum, which will be the product ſought.

Des Cartes, at the beginning of his Geometry, performs Multiplication (and indeed all the other common arithmetical rules) in geometry, or by lines; but this is no more than taking a 4th proportional to three given lines, of which the firſt repreſents unity, and the 2d and 3d the two factors or terms to be multiplied, the product being expreſſed by the 4th proportional; becauſe, in every multiplication, unity or 1 is to either of the two factors, as the other factor is to the product.

MULTIPLICATOR, is the number or quantity by which another is multiplied; and is otherwiſe called the multiplier.

MULTIPLIER, or MULTIPLICATOR, is the number or quantity which multiplies another, called the multiplicand, in any operation of multiplication.

MUNSTER (SEBASTIAN), an eminent German divine and mathematician, was born at Ingelheim in 1489. At the age of 14 he was ſent to Heidelberg to ſtudy. Two years after, he entered the convent of the Cordeliers; where he aſſiduouſly ſtudied divinity, mathematics, and geography. He was the firſt who publiſhed a Chaldee Grammar and Lexicon; and he ſhortly after gave the world a Talmudic Dictionary. He afterwards became profeſſor of the Hebrew language at Baſil. He was one of the firſt who attached himſelf to Luther, and embraced Proteſtantiſm: yet behaved himſelf with great moderation; never concerning himſelf with their diſputes; but ſhut himſelf up at home and purſued his favourite ſtudies, which were mathematics, natural philoſophy, with the Hebrew and other Oriental languages. He publiſhed a great number of books on theſe ſubjects; particularly, a Latin verſion, from the Hebrew, of all the books of the Old Teſtament, with learned notes, printed at Baſil in 1534 and 1546; Joſephus's Hiſtory of the Jews in Latin; a Treatiſe of Dialling, in folio, 1536; Univerſal Coſmography, in 6 books folio, Baſil 1550. For theſe works he was ſtyled the German Strabo; as he was the German Eſdras, for his Oriental writings.

Munſter was a meek-tempered, pacific, ſtudious, retired man, who wrote a great number of books, but never

never meddled in controverſy.—He died of the plague at Baſil, in 1552, at 63 years of age.

MURDERERS, a ſmall ſpecies of ordnance once uſed on ſhipboard; but now out of uſe.

MUSIC, the ſcience of ſound, conſidered as capable of producing melody, or harmony.

Among the Ancients, Muſic was taken in a much more extenſive ſenſe than among the Moderns: what we call the ſcience of Muſic, was by the Ancients rather called Harmonica.

Muſic is one of the ſeven ſciences called liberal, and comprehended alſo among the mathematical ſciences, as having for its object diſcrete quantity or number; not however conſidering it in the abſtract, like arithmetic; but in relation to time and ſound, with intent to conſtitute a delightful harmony.

This ſcience is alſo Theoretical and Practical. Theoretical, which examines the nature and properties of concords and diſcords, explaining the proportions between them by numbers. And Practical, which teaches not only compoſition, or the manner of compoſing tunes, or airs; but alſo the art of ſinging with the voice, and playing on muſical inſtruments.

It appears that Muſic was one of the moſt ancient of the arts; and, of all others, Vocal Muſic muſt doubtleſs have been the firſt kind. For man had not only the various tones of his own voice to make his obſervations on, before any other art or inſtrument was found out, but had the various natural ſtrains of birds to give him occaſion to improve his own voice, and the modulations of ſounds it was capable of. The firſt invention of wind inſtruments Lucretius aſcribes to the obſervation of the winds whiſtling in the hollow reeds. As for other kinds of inſtruments, there were ſo many occaſions for cords or ſtrings, that men could not be long in obſerving their various ſounds; which might give riſe to ſtringed inſtruments. And for the pulſative inſtruments, as drums and cymbals, they might ariſe from the obſervation of the naturally hollow noiſe of concave bodies.

As to the inventors and improvers of Muſic, Plutarch, in one place, aſcribes the firſt invention of it to Apollo; and in another place to Amphion, the ſon of Jupiter and Antiope. The latter indeed, it is pretty generally allowed, firſt brought Muſic into Greece, and invented the lyre.

To him ſucceeded Chiron, the demigod; then Demodocus; Hermes Triſmegiſtus: Olympus; and Orpheus, whom ſome make the firſt introducer of Muſic into Greece, and the inventor of the lyre: to whom add Phemius, and Terpander, who was contemporary with Lycurgus, and ſet his laws to Muſic; to whom alſo ſome attribute the firſt inſtitution of muſical modes, and the invention of the lyre: laſtly, Thales; and Thamyris, who, it has been ſaid, was the firſt inventor of inſtrumental Muſic without ſinging.

Theſe were the eminent muſicians before Homer's time: others of a later date were, Laſus Hermionenſis, Melanippides, Philoxenus, Timotheus, Phrynnis, Epigonius, Lyſander, Simmicus, and Diodorus; who were all of them conſiderable improvers of Muſic. Laſus, it is ſaid, was the firſt author who wrote upon Muſic, in the time of Darius Hyſtaſpis; Epigonius invented an inſtrument of 40 ſtrings, called the Epigonium. Simmicus alſo invented an inſtrument of 35 ſtrings, called a Simmicium; Diodorus improved the Tibia, by adding new holes; and Timotheus the Lyre, by adding a new ſtring; for which he was fined by the Lacedemonians.

As the accounts we have of the inventors of muſical inſtruments among the Ancients are very obſcure, ſo alſo are the accounts of thoſe inſtruments themſelves; of moſt of them indeed we know little more than the bare names.

The general diviſion of inſtruments is, into ſtringed inſtruments, wind inſtruments, and thoſe of the pulſatile kind. Of ſtringed inſtruments, mention is made of the lyra or cithara, the pſalterium, trigonum, ſambuca, pectis, magas, barbiton, teſtudo, epigonium, ſimmicium, and panderon; which were all ſtruck with the hand, or a plectrum. Of wind inſtruments, were the tibia, fiſtula, hydraulic organs, tubæ, cornua, and lituus. And the pulſatile inſtruments were the tympanum, cymbalum, creptaculum, tintinnabulum, crotalum, and ſiſtrum.

Muſic has ever been in the higheſt eſteem in all ages, and among all people; nor could authors expreſs their opinion of it ſtrongly enough, but by inculcating that it was uſed in heaven, and as one of the principal entertainments of the gods, and the ſouls of the bleſſed. The effects aſcribed to it by the Ancients are almoſt miraculous: by its means, it has been ſaid, diſeaſes have been cured, unchaſtity corrected, ſeditions quelled, paſſions raiſed and calmed, and even madneſs occaſioned. Athenæus aſſures us, that anciently all laws, divine and civil, exhortations to virtue, the knowledge of divine and human things, with the lives and actions of illuſtrious men, were written in verſe, and publicly ſung by a chorus to the ſound of inſtruments; which was found the moſt effectual means to impreſs morality on the minds of men, and a right ſenſe of their duty.

Dr. Wallis has endeavoured to account for the ſurpriſing effects attributed to the ancient Muſic; and aſcribes them chiefly to the novelty of the art, and the hyperboles of the ancient writings: nor does he doubt, but the modern Muſic, in like caſes, would produce effects at leaſt as conſiderable as the ancient. The truth is, we can match moſt of the ancient ſtories of this kind in the modern hiſtories. If Timotheus could excite Alexander's fury with the Phrygian mode, and ſooth him into indolence with the Lydian; a more modern muſician has driven Eric, king of Denmark, into ſuch a rage, as to kill his beſt ſervants. Dr. Niewentyt ſpeaks of an Italian who, by varying his Muſic from briſk to ſolemn, and the contrary, could ſo move the ſoul, as to cauſe diſtraction and madneſs; and Dr. South has founded his poem, called Muſica Incantans, on an inſtance he knew of the ſame kind.

Muſic however is found not only to exert its force on the affections, but on the parts of the body alſo: witneſs the Gaſcon knight, mentioned by Mr. Boyle, who could not contain his water at the playing of a bagpipe; and the woman, mentioned by the ſame author, who would burſt into tears at the hearing of a certain tune, with which other people were but a little affected. To ſay nothing of the trite ſtory of the Tarantula, we have an inſtance, in the Hiſtory of the Academy of Sciences, of a muſician being cured of a violent fever,

fever, by a little concert occaſionally played in his room.

Nor are our minds and bodies alone affected with ſounds, but even inanimate bodies are ſo. Kircher ſpeaks of a large ſtone, that would tremble at the ſound of one particular organ pipe; and Morhoff mentions one Petter, a Dutchman, who could break rummer-glaſſes with the tone of his voice. Merſenne alſo mentions a particular part of a pavement, that would ſhake and tremble, as if the earth would open, when the organs played. Mr. Boyle adds, that ſeats will tremble at the ſound of organs; that he has felt his hat do ſo under his hand, at certain notes both of organs and diſcourſe; and that he was well informed every well-built vault would thus anſwer to ſome determinate note.

It has been diſputed among the Learned, whether the Ancients or Moderns beſt underſtood and practiſed Muſic. Some maintain that the ancient art of Muſic, by which ſuch wonderful effects were performed, is quite loſt; and others, that the true ſcience of harmony is now arrived at much greater perfection than was known or practiſed among the Ancients. This point ſeems no other way to be determinable but by comparing the principles and practice of the one with thoſe of the other. As to the theory or principles of harmonics, it is certain we underſtand it better than the Ancients; becauſe we know all that they knew, and have improved conſiderably on their foundations. The great diſpute then lies on the practice; with regard to which it may be obſerved, that among the Ancients, Muſic, in the moſt limited ſenſe of the word, included Harmony, Rythmus, and Verſe; and conſiſted of verſes ſung by one or more voices alternately, or in choirs, ſometimes with the ſound of inſtruments, and ſometimes by voices only. Their muſical faculties, we have juſt obſerved, were Melopœia, Rythmopœia, and Poeſis; the firſt of which may be conſidered under two heads, Melody and Symphony. As to the latter, it ſeems to contain nothing but what relates to the conduct of a ſingle voice, or making what we call Melody. It does not appear that the Ancients ever thought of the concert, or harmony of parts; which is a modern invention, for which we are beholden to Guido Aretine, a Benedictine friar.

Not that the Ancients never joined more voices or inſtruments than one together in the ſame ſymphony; but that they never joined ſeveral voices ſo as that each had a diſtinct and proper melody, which made among them a ſucceſſion of various concords, and were not in every note uniſons, or at the ſame diſtance from each other as octaves. This laſt indeed agrees to the general definition of the word Symphonia; yet it is plain that in ſuch caſes there is but one ſong, and all the voices perform the ſame individual melody. But when the parts differ, not by the tenſion of the whole, but by the different relations of the ſucceſſive notes, this is the modern art, which requires ſo peculiar a genius, and on which account the modern Muſic ſeems to have much the advantage of the ancient. For farther ſatisfaction on this head, ſee Kircher, Perrault, Wallis, Malcolm, Cerceau, and others; who unanimouſly agree, that after all the pains they have taken to know the true ſtate of the Muſic of the Ancients, they could not find the leaſt reaſon to think there was any ſuch thing in their days as Muſic in parts.

The ancient muſical notes are very myſterious and perplexed: Boethius and Gregory the Great firſt put them into a more eaſy and obvious method. In the year 1204, Guido Aretine, a Benedictine of Arezzo in Tuſcany, firſt introduced the uſe of a ſtaff with five lines, on which, with the ſpaces, he marked his notes by ſetting a point up and down upon them, to denote the riſe and fall of the voice: though Kircher ſays this artifice was in uſe before Guido's time.

Another contrivance of Guido's was to apply the ſix muſical ſyllables, *ut*, *re*, *mi*, *fa*, *ſol*, *la*, which he took out of the Latin hymn,

UT queant laxis REſonare fibris
MIra geſtorum FAmuli tuorum,
SOLve polluti LAbii reatum,
O Pater Alme.

We find another application of them in the following lines.

UT REſidet MIſerum FAtum, SOLitoſque LAbores
Aevi, ſit dulcis muſica noſter amor.

Beſides his notes of Muſic, by which, according to Kircher, he diſtinguiſhed the tones, or modes, and the ſeats of the ſemitones, he alſo invented the ſcale, and ſeveral muſical inſtruments, called polyplectra, as ſpinets and harpſichords.

The next conſiderable improvement was in 1330, when Joannes Muria, or de Muris, doctor at Paris (or as Bayle and Geſner make him, an Engliſhman), invented the different figures of notes, which expreſs the times or length of every note, at leaſt their true relative proportions to one another, now called longs, breves, ſemi-breves, crotchets, quavers, &c.

The moſt ancient writer on Muſic was Laſus Hermionenſis; but his works, as well as thoſe of many others, both Greek and Roman, are loſt. Ariſtoxenus, diſciple of Ariſtotle, is the earlieſt author extant on the ſubject: after whom came Euclid, author of the Elements of Geometry; and Ariſtides Quintilianus wrote after Cicero's time. Alypius ſtands next; after him Gaudentius the philoſopher, and Nicomachus the Pythagorean, and Bacchius. Of which ſeven Greek authors we have a fair copy, with a tranſlation and notes, by Meibomius. Ptolomy, the celebrated aſtronomer, wrote in Greek on the principles of harmonics, about the time of the emperor Antoninus Pius. This author keeps a medium between the Pythagoreans and Ariſtoxenians. He was ſucceeded at a conſiderable diſtance by Manuel Bryennius.

Of the Latins, we have Boetius, who wrote in the time of Theodoric the Goth; and one Caſſiodorus, about the ſame time; Martianus, and St. Auguſtine, not far remote.

And of the moderns are Zarlin, Salinas, Vincenzo Galileo, Doni, Kircher, Merſenne, Paran, De Caux, Perrault, Des Cartes, Wallis, Holder, Malcolm, Rouſſeau, &c.

Musical *Numbers*, are the numbers 2, 3, and 5, together with their compoſites. They are ſo called, becauſe all the intervals of muſic may be expreſſed by ſuch numbers. This is now generally admitted by muſical

muſical theoriſts. Mr. Euler ſeems to ſuppoſe, that 7 or other primes might be introduced; but he ſpeaks of this as a doubtful and difficult matter. Here 2 corresponds to the octave, 3 to the fifth, or rather to the 12th, and 5 to the third major, or rather the seventeenth. From theſe three may all other intervals be found.

MUSICAL *Proportion*, or Harmonical Proportion, is when, of four terms, the firſt is to the 4th, as the difference of the 1ſt and 2d is to the difference of the 3d and 4th: as 2, 3, 4, and 8 are in Muſical proportion, becauſe 2 : 8 : : 1 : 4. And hence, if there be only three terms, the middle term ſupplying the place of both the 2d and 3d, the 1ſt is to the 3d, as the difference of the 1ſt and 2d, is to the difference of the 2d and 3d: as in theſe 2, 3, 6; where 2 : 6 : : 1 : 3. See HARMONICAL *Proportion*.

MUSSCHENBROEK (PETER), a very diſtinguiſhed natural philoſopher and mathematician, was born at Utrecht a little before 1700. He was firſt profeſſor of theſe ſciences in his own univerſity, and afterwards invited to the chair at Leyden, where he died full of reputation and honours in 1761. He was a member of ſeveral academies, particularly the Academy of Sciences at Paris. He publiſhed ſeveral works in Latin, all of them ſhewing his great penetration and accuracy. As,

1. His Elements of Phyſico-Mathematics, in 1726.
2. Elements of Phyſics, in 1736.
3. Inſtitutions of Phyſics; containing an abridgment of the new diſcoveries made by the Moderns; in 1748.
4. Introduction to Natural Philoſophy; which he began to print in 1760; and which was completed and publiſhed at Leyden, in 1762, by M. Lulofs, after the death of the author. It was tranſlated into French by M. Sigaud de la Fond, and publiſhed at Paris in 1769, in 3 vols 4to; under the title of A Courſe of Experimental and Mathematical Phyſics.

He had alſo ſeveral papers, chiefly on meteorology, printed in the volumes of Memoirs of the Academy of Sciences, viz, in thoſe of the years 1734, 1735, 1736, 1753, 1756, and 1760.

MUTULE, a kind of ſquare modillion in the Doric frize.

MYRIAD, the number of 10,000, or ten thouſand.

N.

NAB NAP

NABONASSAR, firſt king of the Chaldeans; memorable for the Jewiſh era which bears his name, which began on Wedneſday February 26th in the 3967th year of the Julian period, or 747 years before Chriſt; the years of this epoch being Egyptian ones, of 365 days each. This is a remarkable era in chronology, becauſe Ptolomy aſſures us there were aſtronomical obſervations made by the Chaldeans from Nabonaſſar to his time; alſo Ptolomy, and the other aſtronomers, account their years from that epoch.

Nabonaſſar was the firſt king of the Chaldeans or Babylonians. Theſe having revolted from the Medes, who had overthrown the Aſſyrian monarchy, did, under Nabonaſſar, found a dominion, which was much increaſed under Nebuchadnezzar. It is probable this Nabonaſſar is that Baladan in the 2d Book of Kings, xx, 12, father of Merodach, who ſent ambaſſadors to Hezekiah. See 2 Chron. xxii.

NADIR, that point of the heavens diametrically under our feet, or oppoſite to the zenith, which is directly over our heads. The zenith and Nadir are the two poles of the horizon, each being 90° diſtant from it.

The Sun's NADIR, is the axis of the cone projected by the ſhadow of the earth: ſo called, becauſe that axis being prolonged, gives a point in the ecliptic diametrically oppoſite to the ſun.

NAKED, in Architecture, as the Naked of a wall, &c, is the ſurface, or plane, from whence the projectures ariſe; or which ſerves as a ground to the projectures.

NAPIER, or NEPER (JOHN), baron of Merchiſton in Scotland, inventor of the logarithms, was the eldeſt ſon of Sir Archibald Napier of Merchiſton, and born in the year 1550. Having given early indications of great natural parts, his father was careful to have them cultivated by a liberal education. After going through the ordinary courſe of education at the univerſity of St. Andrew's, he made the tour of France, Italy, and Germany. On his return to his native country, his literature and other fine accompliſhments ſoon rendered him conſpicuous; he however retired from the world to purſue literary reſearches, in which he made an uncommon progreſs, as appears by the ſeveral uſeful diſcoveries with which he afterwards favoured mankind. He chiefly applied himſelf to the ſtudy of mathematics; without however neglecting that of the Scriptures; in both of which he diſcovered the moſt extenſive knowledge and profound penetration. His Eſſay upon the book of the Apocalypſe indicates the moſt acute

inveſtigation; though time hath diſcovered that his calculations concerning particular events had proceeded upon fallacious data. But what has chiefly rendered his name famous, was his great and fortunate diſcovery of logarithms in trigonometry, by which the eaſe and expedition in calculation have ſo wonderfully aſſiſted the ſcience of aſtronomy and the arts of practical geometry and navigation. Napier, having a great attachment to aſtronomy, and ſpherical trigonometry, had occaſion to make many numeral calculations of ſuch triangles, with ſines, tangents, &c; and theſe being expreſſed in large numbers, they hence occaſioned a great deal of labour and trouble: To ſpare themſelves part of this labour, Napier, and other authors about his time, ſet themſelves to find out certain ſhort modes of calculation, as is evident from many of their writings. To this neceſſity, and theſe endeavours it is, that we owe ſeveral ingenious contrivances; particularly the computation by Napier's Rods, and ſeveral other curious and ſhort methods that are given in his *Rabdologia*; and at length, after trials of many other means, the moſt complete one of logarithms, in the actual conſtruction of a large table of numbers in arithmetical progreſſion, adapted to a ſet of as many others in geometrical progreſſion. The property of ſuch numbers had been long known, viz, that the addition of the former anſwered to the multiplication of the latter, &c; but it wanted the neceſſity of ſuch very troubleſome calculations as thoſe above mentioned, joined to an ardent diſpoſition, to make ſuch a uſe of that property. Perhaps alſo this diſpoſition was urged into action by certain attempts of this kind which it ſeems were made elſewhere; ſuch as the following, related by Wood in his Athenæ Oxonienſes, under the article Briggs, on the authority of Oughtred and Wingate, viz, "That one Dr. Craig a Scotchman, coming out of Denmark into his own country, called upon John Neper baron of Marcheſton near Edinburgh, and told him among other diſcourſes of a new invention in Denmark (by Longomontanus as 'tis ſaid) to ſave the tedious multiplication and diviſion in aſtronomical calculations. Neper being ſolicitous to know farther of him concerning this matter, he could give no other account of it, than that it was by proportionable numbers. Which hint Neper taking, he deſired him at his return to call upon him again. Craig, after ſome weeks had paſſed, did ſo, and Neper then ſhewed him a rude draught of that he called *Canon Mirabilis Logarithmorum*. Which draught, with ſome alterations, he printing in 1614, it came forthwith into the hands of our author Briggs, and into thoſe of William Oughtred, from whom the relation of this matter came."

Whatever might be the inducement however, Napier publiſhed his invention in 1614, under the title of *Logarithmorum Canonis Deſcriptio, &c*, containing the conſtruction and canon of his logarithms, which are thoſe of the kind that is called hyperbolic. This work coming preſently to the hands of Mr. Briggs, then Profeſſor of Geometry at Greſham College in London, he immediately gave it the greateſt encouragement, teaching the nature of the logarithms in his public lectures, and at the ſame time recommending a change in the ſcale of them, by which they might be advantageouſly altered to the kind which he afterwards computed himſelf, which are thence called Briggs's Logarithms, and are thoſe now in common uſe. Mr. Briggs alſo preſently wrote to lord Napier upon this propoſed change, and made journeys to Scotland the two following years, to viſit Napier, and conſult him about that alteration, before he ſet about making it. Briggs, in a letter to archbiſhop Uſher, March 10, 1615, writes thus: "Napier lord of Markinſton hath ſet my head and hands at work with his new and admirable logarithms. I hope to ſee him this ſummer, if it pleaſe God; for I never ſaw a book which pleaſed me better, and made me more wonder." Briggs accordingly made him the viſit, and ſtaid a month with him.

The following paſſage, from the life of Lilly the aſtrologer, contains a curious account of the meeting of thoſe two illuſtrious men. "I will acquaint you (ſays Lilly) with one memorable ſtory related unto me by John Marr, an excellent mathematician and geometrician, whom I conceive you remember. He was ſervant to King James and Charles the Firſt. At firſt when the lord Napier, or Marchiſton, made public his logarithms, Mr. Briggs, then reader of the aſtronomy lectures at Greſham College in London, was ſo ſurpriſed with admiration of them, that he could have no quietneſs in himſelf until he had ſeen that noble perſon the lord Marchiſton, whoſe only invention they were: he acquaints John Marr herewith, who went into Scotland before Mr. Briggs, purpoſely to be there when theſe two ſo learned perſons ſhould meet. Mr. Briggs appoints a certain day when to meet at Edinburgh; but failing thereof, the lord Napier was doubtful he would not come. It happened one day as John Marr and the lord Napier were ſpeaking of Mr. Briggs; 'Ah, John (ſaid Marchiſton), Mr. Briggs will not now come.' At the very inſtant one knocks at the gate; John Marr haſted down, and it proved Mr. Briggs to his great contentment. He brings Mr. Briggs up into my lord's chamber, where almoſt one quarter of an hour was ſpent, each beholding other almoſt with admiration before one word was ſpoke. At laſt Mr. Briggs began: 'My lord, I have undertaken this long journey purpoſely to ſee your perſon, and to know by what engine of wit or ingenuity you came firſt to think of this moſt excellent help into aſtronomy, viz, the logarithms; but, my lord, being by you found out, I wonder no body elſe found it out before, when now known it is ſo eaſy.' He was nobly entertained by the lord Napier; and every ſummer after that, during the lord's being alive, this venerable man Mr. Briggs went purpoſely into Scotland to viſit him."

Napier made alſo conſiderable improvements in ſpherical trigonometry &c, particularly by his Catholic or Univerſal Rule, being a general theorem by which he reſolves all the caſes of right-angled ſpherical triangles in a manner very ſimple, and eaſy to be remembered, namely, by what he calls the Five Circular Parts. His Conſtruction of Logarithms too, beſide the labour of them, manifeſts the greateſt ingenuity. Kepler dedicated his Ephemerides to Napier, which were publiſhed in the year 1617; and it appears from many paſſages in his letter about this time, that he accounted Napier to be the greateſt man of his age in the particular department to which he applied his abilities.

The laſt literary exertion of this eminent perſon was the publication of his *Rabdology and Promptuary*, in the year 1617; ſoon after which he died at Marchiſton, the 3d of April in the ſame year, in the 68th year of his age.—The liſt of his works is as follows:

1. A Plain Diſcovery of the Revelation of St. John; 1593.

2. *Logarithmorum Canonis Deſcriptio*; 1614.

3. *Mirifici Logarithmorum Canonis Conſtructio; et eorum ad Naturales ipſorum numeros habitudines; una cum appendice, de alia eaque præſtantiore Logarithmorum ſpecie condenda. Quibus acceſſere propoſitiones ad triangula ſphærica faciliore calculo reſolvenda. Una cum Annotationibus aliquot doctiſſimi D. Henrici Briggii in eas, & memoratam appendicem.* Publiſhed by the author's ſon in 1619.

4. *Rabdologia, ſeu Numerationis per Virgulas, libri duo*; 1617. This contains the deſcription and uſe of the Bones or Rods; with ſeveral other ſhort and ingenious modes of calculation.

5. His Letter to Anthony Bacon (the original of which is in the archbiſhop's library at Lambeth), intitled, Secret Inventions, Profitable and Neceſſary in theſe days for the Defence of this Iſland, and withſtanding Strangers Enemies to God's Truth and Religion; dated June 2, 1596.

NAPIER's *Bones*, or *Rods*, an inſtrument contrived by lord Napier, for the more eaſy performing of the arithmetical operations of multiplication, diviſion, &c. Theſe rods are five in number, made of Bone, ivory, horn, wood, or paſteboard, &c. Their faces are divided into nine little ſquares (fig. 7, pl. 16); each of which is parted into two triangles by diagonals. In theſe little ſquares are written the numbers of the multiplication-table; in ſuch manner as that the units, or right-hand figures, are found in the right-hand triangle: and the tens, or the left-hand figures, in the left-hand triangle; as in the figure.

To Multiply Numbers by NAPIER's *Bones*. Diſpoſe the rods in ſuch manner, as that the top figures may exhibit the multiplicand; and to theſe, on the left-hand, join the rod of units: in which ſeek the right-hand figure of the multiplier: and the numbers correſponding to it, in the ſquares of the other rods, write out, by adding the ſeveral numbers occurring in the ſame rhomb together, and their ſums. After the ſame manner write out the numbers correſponding to the other figures of the multiplier; diſpoſing them under one another as in the common multiplication; and laſtly add the ſeveral numbers into one ſum.

For example, ſuppoſe the multiplicand 5978, and the multiplier 937. From the outermoſt triangle on the right-hand (fig. 8, pl. 16) which correſponds to the right-hand figure of the multiplier 7, write out the figure 6, placing it under the line. In the next rhomb towards the left, add 9 and 5; their ſum being 14, write the right-hand figure 4, againſt 6; carrying the left-hand figure 1 to 4 and 3, which are found in the next rhomb: join the ſum 8 to 46, already ſet down. After the ſame manner, in the laſt rhomb, add 6 and 5, and the latter figure of the ſum 11, ſet down as before, and carry 1 to the 3 found in the left-hand triangle; the ſum 4 join as before on the left-hand of 1846. Thus you will have 41846 for the product of 5978 by 7. And in the ſame manner are to be found the products for the other figures of the multiplier; after which the whole is to be added together as uſual.

To perform Diviſion by NAPIER's *Bones*. Diſpoſe the rods ſo, as that the uppermoſt figures may exhibit the diviſor; to theſe on the left-hand, join the rod of units. Deſcend under the diviſor, till you meet thoſe figures of the dividend in which it is firſt required how oft the diviſor is found, or at leaſt the next leſs number, which is to be ſubtracted from the dividend; then the number correſponding to this, in the place of units, ſet down for a quotient. And by determining the other parts of the quotient after the ſame manner, the diviſion will be completed.

For example; ſuppoſe the dividend 5601386, and the diviſor 5978; ſince it is firſt enquired how often 5978 is found in 56013, deſcend under the diviſor (fig. 8) till in the loweſt ſeries you find the number 53802, approaching neareſt to 56013; the former of which is to be ſubtracted from the latter, and the figure 9 correſponding to it in the rod of units ſet down for the quotient. To the remainder 2211 join the following figure 8 of the dividend; and the number 17934 being found as before for the next leſs number to it, the correſponding number 3 in the rod of units is to be ſet down for the next figure of the quotient. After the ſame manner the third and laſt figure of the quotient will be found to be 7; and the whole quotient 937.

NATIVITY, in Aſtrology, the ſcheme or figure of the heavens, and particularly of the twelve houſes, at the moment when a perſon was born; called alſo the Horoſcope.

To Caſt the NATIVITY, is to calculate the poſition of the heavens, and erect the figure of them for the time of birth.

NATURAL *Day, Year, &c.* See DAY, YEAR, &c.

NATURAL *Horizon*, is the ſenſible or phyſical horizon.

NATURAL *Magic*, is that which only makes uſe of natural cauſes; ſuch as the Treatiſe of J. Bapt. Porta, Magia Naturalia.

NATURAL *Philoſophy*, otherwiſe called *Phyſics*, is that ſcience which conſiders the powers of nature, the properties of natural bodies, and their actions upon one another.

Laws of NATURE, are certain axioms, or general rules, of motion and reſt, obſerved by natural bodies in their actions upon one another. Of theſe Laws, Sir I. Newton has eſtabliſhed three:

1ſt LAW.—That every body perſeveres in the ſame ſtate, either of reſt, or uniform rectilinear motion; unleſs it is compelled to change that ſtate by the action of ſome foreign force or agent. Thus, projectiles perſevere in their motions, except ſo far as they are

retarded by the reſiſtance of the air, and the action of gravity: and thus a top, once ſet up in motion, only ceaſes to turn round, becauſe it is reſiſted by the air, and by the friction of the plane upon which it moves. Thus alſo the larger bodies of the planets and comets preſerve their progreſſive and circular motions a long time undiminiſhed, in regions void of all ſenſible reſiſtance.—As body is paſſive in receiving its motion, and the direction of its motion, ſo it retains them, or perſeveres in them, without any change, till it be acted upon by ſomething external.

2d Law.—The Motion, or Change of Motion, is always proportional to the moving force by which it is produced, and in the direction of the right line in which that force is impreſſed. If a certain force produce a certain motion, a double force will produce double the motion, a triple force triple the motion, and ſo on. And this motion, ſince it is always directed to the ſame point with the generating force, if the body were in motion before, is either to be added to it, as where the motions conſpire; or ſubtracted from it, as when they are oppoſite; or combined obliquely, when oblique: being always compounded with it according to the determination of each.

3d Law.—Re-action is always contrary, and equal to action; or the actions of two bodies upon one another, are always mutually equal, and directed contrary ways; and are to be eſtimated always in the ſame right line. Thus, whatever body preſſes or draws another, is equally preſſed or drawn by it. So, if I preſs a ſtone with my finger, the finger is equally preſſed by the ſtone: if a horſe draw a weight forward by a rope, the horſe is equally oppoſed or drawn back towards the weight; the equal tenſion or ſtretch of the rope hindering the progreſs of the one, as it promotes that of the other. Again, if any body, by ſtriking on another, do in any manner change its motion, it will itſelf, by means of the other, undergo alſo an equal change in its own motion, by reaſon of the equality of the preſſure. When two bodies meet, each endeavours to perſevere in its ſtate, and reſiſts any change: and becauſe the change which is produced in either may be equally meaſured by the action which it excites upon the other, or by the reſiſtance which it meets with from it, it follows that the changes produced in the motions of each are equal, but are made in contrary directions: the one acquires no new force but what the other loſes in the ſame direction; nor does this laſt loſe any force but what the other acquires; and hence, though by their colliſions, motion paſſes from the one to the other, yet the ſum of their motions, eſtimated in a given direction, is preſerved the ſame, and is unalterable by their mutual actions upon each other. In theſe actions the changes are equal; not thoſe, we mean, of the velocities, but thoſe of the motions, or momentums; the bodies being ſuppoſed free from any other impediments. For the *changes of velocities, which are likewiſe made contrary ways*, inaſmuch as the motions are equally changed, are reciprocally proportional to the bodies or maſſes.

This law obtains alſo in attractions.

NAVIGATION, is the art of conducting a ſhip at ſea from one port or place to another.

This is perhaps the moſt uſeful of all arts, and is of the higheſt antiquity. It may be impoſſible to ſay who were the inventors of it; but it is probable that many people cultivated it, independent of each other, who inhabited the coaſts of the ſea, and had occaſion, or found it convenient, to convey themſelves upon the water from place to place; beginning from rafts and logs of wood, and gradually improving in the ſtructure and management of their veſſels, according to the length of time, and extent of their voyages. Writers however aſcribe the invention of this art to different perſons, or nations, according to their different ſources of information. Thus,

The poets refer the invention of Navigation to Neptune, ſome to Bacchus, others to Hercules, to Jaſon, or to Janus, who it is ſaid made the firſt ſhip. Hiſtorians aſcribe it to the Æginetes, the Phœnicians, Tyrians, and the ancient inhabitants of Britain. Some are of opinion that the firſt hint was taken from the flight of the kite; and ſome, as Oppian (De Piſcibus, lib. 1) from the fiſh called Nautilus; while others aſcribe it to accident; and others again deriving the hint and invention from Noah's ark.

However, hiſtory repreſents the Phœnicians, eſpecially thoſe of the capital Tyre, as the firſt navigators that made any extenſive progreſs in the art, ſo far as has come to our knowledge; and indeed it muſt have been this very art that made their city what it was. For this purpoſe, Lebanon, and the other neighbouring mountains, furniſhing them with excellent wood for ſhip-building, they were ſpeedily maſters of a numerous fleet, with which conſtantly hazarding new navigations, and ſettling new trades, they ſoon arrived at an incredible pitch of opulence and populouſneſs; ſo as to be in a condition to ſend out colonies, the principal of which was that of Carthage; which, keeping up their Phœnician ſpirit of commerce, in time far ſurpaſſed Tyre itſelf; ſending their merchant ſhips through Hercules's pillars, now the ſtraits of Gibraltar, and thence along the weſtern coaſts of Africa and Europe; and even, according to ſome authors, to America itſelf. The city of Tyre being deſtroyed by Alexander the Great, its Navigation and commerce were transferred by the conqueror to Alexandria, a new city, well ſituated for theſe purpoſes, and propoſed for the capital of the empire of Aſia, the conqueſt of which Alexander then meditated. And thus aroſe the Navigation of the Egyptians; which was afterwards ſo cultivated by the Ptolomies, that Tyre and Carthage were quite forgotten.

Egypt being reduced to a Roman province after the battle of Actium, its trade and Navigation fell into the hands of Auguſtus; in whoſe time Alexandria was only inferior to Rome; and the magazines of the capital of the world were wholly ſupplied with merchandizes from the capital of Egypt.

At length, Alexandria itſelf underwent the fate of Tyre and Carthage; being ſurpriſed by the Saracens, who, *in ſpite of* the emperor Heraclius, overſpread the northern coaſts of Africa, &c; whence the merchants being driven, Alexandria has ever ſince been in a languiſhing ſtate, though ſtill it has a conſiderable part of the commerce of the chriſtian merchants trading to the Levant.

The fall of Rome and its empire drew along with it not only that of learning and the polite arts, but that of

Navigation alſo; the barbarians, into whoſe hands it fell, contenting themſelves with the ſpoils of the induſtry of their predeceſſors.

But no ſooner were the brave among thoſe nations well ſettled in their new provinces; ſome in Gaul, as the Franks; others in Spain, as the Goths; and others in Italy, as the Lombards; but they began to learn the advantages of Navigation and commerce, with the methods of managing them, from the people they ſubdued; and this with ſo much ſucceſs, that in a little time ſome of them became able to give new leſſons, and ſet on foot new inſtitutions for its advantage. Thus it is to the Lombards we uſually aſcribe the invention and uſe of banks, book-keeping, exchanges, rechanges, &c.

It does not appear which of the European people, after the ſettlement of their new maſters, firſt betook themſelves to Navigation and commerce.—Some think it began with the French; though the Italians ſeem to have the juſter title to it, and are uſually conſidered as the reſtorers of them, as well as of the polite arts, which had been baniſhed together from the time the empire was torn aſunder. It is the people of Italy then, and particularly thoſe of Venice and Genoa, who have the glory of this reſtoration; and it is to their advantageous ſituation for Navigation that they in a great meaſure owe their glory. From about the time of the 6th century, when the inhabitants of the iſlands in the bottom of the Adriatic began to unite together, and by their union to form the Venetian ſtate, their fleets of merchantmen were ſent to all the parts of the Mediterranean; and at laſt to thoſe of Egypt, particularly Cairo, a new city, built by the Saracen princes on the eaſtern banks of the Nile, where they traded for their ſpices and other products of the Indies. Thus they flouriſhed, increaſed their commerce, their Navigation, and their conqueſts on the terra firma, till the league of Cambray in 1508, when a number of jealous princes conſpired to their ruin; which was the more eaſily effected by the diminution of their Eaſt-India commerce, of which the Portugueſe had got one part, and the French another. Genoa too, which had cultivated Navigation at the ſame time with Venice, and that with equal ſucceſs, was a long time its dangerous rival, diſputed with it the empire of the ſea, and ſhared with it the trade of Egypt; and other parts both of the eaſt and weſt.

Jealouſy ſoon began to break out; and the two republics coming to blows, there was almoſt continual war for three centuries, before the ſuperiority was aſcertained; when, towards the end of the 14th century, the battle of Chioza ended the ſtrife: the Genoeſe, who till then had uſually the advantage, having now loſt all; and the Venetians almoſt become deſperate, at one happy blow, beyond all expectation, ſecured to themſelves the empire of the ſea, and the ſuperiority in commerce.

About the ſame time that Navigation was retrieved in the ſouthern parts of Europe, a new ſociety of merchants was formed in the north, which not only carried commerce to the greateſt perfection it was capable of, till the diſcovery of the Eaſt and Weſt Indies, but alſo formed a new ſcheme of laws for the regulation of it, which ſtill obtain under the name of, *Uſes and Cuſtoms of the Sea*. This ſociety is that celebrated league of the Hanſe-towns, begun about the year 1164.

The art of Navigation has been greatly improved in modern times, both in reſpect of the form of the veſſels themſelves, and the methods of working or conducting them. The uſe of rowers is now entirely ſuperceded by the improvements made in the ſails, rigging, &c. It is alſo very probable, that the Ancients were neither ſo well ſkilled as the Moderns, in finding the latitudes, nor in ſteering their veſſels in places of difficult Navigation, as the Moderns. But the greateſt advantage which theſe have over the Ancients, is from the mariner's compaſs, by which they are enabled to find their way with as much facility in the midſt of an immeaſurable ocean, as the Ancients could have done by creeping along the coaſt, and never going out of ſight of land. Some people indeed contend, that this is no new invention, but that the Ancients were acquainted with it. They ſay, it was impoſſible for Solomon's ſhips to go to Ophir, Tarſhiſh, and Parvaim, which laſt they will have to be Peru, without this uſeful inſtrument. They inſiſt, that it was impoſſible for the Ancients to be acquainted with the attractive virtue of the magnet, without knowing its polarity. They even affirm, that this property of the magnet is plainly mentioned in the book of Job, where the loadſtone is called topaz, or the ſtone that turns itſelf. But, not to mention that Mr. Bruce has lately made it appear highly probable that Solomon's ſhips made no more than coaſting voyages, it is certain that the Romans, who conquered Judea, were ignorant of this inſtrument; and it is very probable, that ſo uſeful an invention, if once it had been commonly known to a nation, would never have been forgotten, or perfectly concealed from ſo prudent a people as the Romans, who were ſo much intereſted in the diſcovery of it.

Among thoſe who do agree that the mariner's compaſs is a modern invention, it has been much diſputed who was the inventor. Some give the honour of it to Flavio Gioia of Amalfi in Campania, about the beginning of the 14th century; while others ſay that it came from the eaſt, and was earlier known in Europe. But, at whatever time it was invented, it is certain, that the mariner's compaſs was not commonly uſed in Navigation before the year 1420. In that year the ſcience was conſiderably improved under the auſpices of Henry duke of Viſeo, brother to the king of Portugal. In the year 1485, Roderic and Joſeph, phyſicians to king John the 2d of Portugal, together with one Martin de Bohemia, a Portugueſe native of the iſland of Fayal, and pupil to Regiomontanus, calculated tables of the ſun's declination for the uſe of ſailors, and recommended the aſtrolabe for taking obſervations at ſea. The celebrated Columbus, it is ſaid, availed himſelf of Martin's inſtructions, and improved the Spaniards in the knowledge of this art; for the farther progreſs of which, a lecture was afterwards founded at Seville by the emperor Charles the 5th.

The diſcovery of the variation of the compaſs, is claimed by Columbus, and by Sebaſtian Cabot. The former certainly did obſerve this variation without having heard of it from any other perſon, on the 14th of September 1492, and it is very probable that Cabot might do the ſame. At that time it was found that there was no variation at the Azores, for which rea-

ſon

ſon ſome geographers made that the firſt meridian, though it has ſince been diſcovered that the variation alters in time. The uſe of the croſs-ſtaff now began to be introduced among ſailors. This ancient inſtrument is deſcribed by John Werner of Nuremberg, in his annotations on the firſt book of Ptolomy's Geography, printed in 1514: he recommends it for obſerving the diſtance between the moon and ſome ſtar, from which to determine the longitude.

At this time the art of Navigation was very imperfect, from the uſe of the plane chart, which was the only one then known, and which, by its groſs errors, muſt have greatly miſled the mariner, eſpecially in places far diſtant from the equator; and alſo from the want of books of inſtruction for ſeamen.

At length two Spaniſh treatiſes came out, the one by Pedro de Medina, in 1545; and the other by Martin Cortes, or Curtis as it is printed in Engliſh, in 1556, though the author ſays he compoſed it at Cadiz in 1545, containing a complete ſyſtem of the art as far as it was then known. Medina, in his dedication to Philip prince of Spain, laments that multitudes of ſhips daily periſhed at ſea, becauſe there were neither teachers of the art, nor books by which it might be learned; and Cortes, in his dedication, boaſts to the emperor, that he was the firſt who had reduced Navigation into a compendium, valuing himſelf much on what he had performed. Medina defended the plane chart; but he was oppoſed by Cortes, who ſhewed its errors, and endeavoured to account for the variation of the compaſs, by ſuppoſing the needle was influenced by a magnetic pole, different from that of the world, and which he called the *point attractive*: which notion has been farther proſecuted by others. Medina's book was ſoon tranſlated into Italian, French, and Flemiſh, and ſerved for a long time as a guide to foreign navigators. However, Cortes was the favourite author of the Engliſh nation, and was tranſlated in 1561, by Richard Eden, while Medina's work was much neglected, though tranſlated alſo within a ſhort time of the other. At that time a ſyſtem of Navigation conſiſted of materials ſuch as the following: An account of the Ptolomaic hypotheſis, and the circles of the ſphere; of the roundneſs of the earth, the longitudes, latitudes, climates, &c, and eclipſes of the luminaries; a calendar; the method of finding the prime, epact, moon's age, and tides; a deſcription of the compaſs, an account of its variation, for the diſcovering of which Cortes ſaid an inſtrument might eaſily be contrived; tables of the ſun's declination for 4 years, in order to find the latitude from his meridian altitude; directions to find the ſame by certain ſtars: of the courſe of the ſun and moon; the length of the days; of time and its diviſions; the method of finding the hour of the day and night; and laſtly, a deſcription of the ſea-chart, on which to diſcover where the ſhip is; they made uſe alſo of a ſmall table, that ſhewed, upon an alteration of one degree of the latitude, how many leagues were run on each rhumb, together with the departure from the meridian; which might be called a table of diſtance and departure, as we have now a table of difference of latitude and departure. Beſides, ſome inſtruments were deſcribed, eſpecially by Cortes; ſuch as, one to find the place and declination of the ſun, with the age and place of the moon; certain dials, the aſtrolabe, and croſs-ſtaff; with a complex machine to diſcover the hour and latitude at once.

About the ſame time propoſals were made for finding the longitude by obſervations of the moon. In 1530, Gemma Friſius adviſed the keeping of the time by means of ſmall clocks or watches, then newly invented, as he ſays. He alſo contrived a new ſort of croſs-ſtaff, and an inſtrument called the Nautical Quadrant; which laſt was much praiſed by William Cuningham, in his Coſmographical Glaſs, printed in the year 1559.

In the year 1537 Pedro Nunez, or Nonius, publiſhed a book in the Portugueſe language, to explain a difficulty in Navigation, propoſed to him by the commander Don Martin Alphonſo de Suſa. In this work he expoſes the errors of the plane chart, and gives the ſolution of ſeveral curious aſtronomical problems; among which is that of determining the latitude from two obſervations of the ſun's altitude and the intermediate azimuth being given. He obſerved, that though the rhumbs are ſpiral lines, yet the direct courſe of a ſhip will always be in the arch of a great circle, by which the angle with the meridians will continually change: all that the ſteerſman can here do for preſerving the original rhumb, is to correct theſe deviations as ſoon as they appear ſenſible. But thus the ſhip will in reality deſcribe a courſe without the rhumb-line intended; and therefore his calculations for aſſigning the latitude, where any rhumb-line croſſes the ſeveral meridians, will be in ſome meaſure erroneous. He invented a method of dividing a quadrant by means of concentric circles, which, after being much improved by Dr. Halley, is uſed at preſent, and is called a Nonius.

In 1577, Mr William Bourne publiſhed a treatiſe, in which, by conſidering the irregularities in the moon's motion, he ſhews the errors of the ſailors in finding her age by the epact, and alſo in determining the hour from obſerving on what point of the compaſs the ſun and moon appeared. In ſailing towards high latitudes he adviſes to keep the reckoning by the globe, as the plane chart is moſt erroneous in ſuch ſituations. He deſpairs of our ever being able to find the longitude, unleſs the variation of the compaſs ſhould be occaſioned by ſome ſuch attractive point as Cortes had imagined; of which however he doubts: but as he had ſhewn how to find the variation at all times, he adviſes to keep an account of the obſervations, as uſeful for finding the place of the ſhip; which advice was proſecuted at large by Simon Stevin in a treatiſe publiſhed at Leyden in 1599; the ſubſtance of which was the ſame year printed at London in Engliſh by Mr. Edward Wright, intitled the *Haven-finding Art*. In the ſame old tract alſo is deſcribed the way by which our ſailors eſtimate the rate of a ſhip in her courſe, by the inſtrument called the Log. The author of this contrivance is not known; neither was it farther noticed till 1607, when it is mentioned in an Eaſt-India voyage publiſhed by Purchas: but from this time it became common, and mentioned by all authors on Navigation; and it ſtill continues to be uſed as at firſt, though many attempts have been made to improve it, and contrivances propoſed to ſupply its place; ſome of which have ſucceeded in ſtill water, but proved uſeleſs in a ſtormy ſea.

In

In 1581 Michael Coignet, a native of Antwerp, publiſhed a Treatiſe, in which he animadverted on Medina. In this he ſhewed, that as the rhumbs are ſpirals, making endleſs revolutions about the poles, numerous errors muſt ariſe from their being repreſented by ſtraight lines on the ſea-charts; but though he hoped to find a remedy for theſe errors, he was of opinion that the propoſals of Nonius were ſcarcely practicable, and therefore in a great meaſure uſeleſs. In treating of the ſun's declination, he took notice of the gradual decreaſe in the obliquity of the ecliptic; he alſo deſcribed the Croſs-Staff with three tranſverſe pieces, as it was then in common uſe among the ſailors. He likewiſe gave ſome inſtruments of his own invention; but all of them are now laid aſide, excepting perhaps his Nocturnal. He conſtructed a ſea-table, to be uſed by ſuch as ſailed beyond the 60th degree of latitude; and at the end of the book is delivered a Method of Sailing on a Parallel of Latitude, by means of a ring dial and a 24 hour glaſs.

In the ſame year Mr. Robert Norman publiſhed his Diſcovery of the Dipping-needle, in a pamphlet called the New Attractive; to which is always ſubjoined Mr. William Burroughs's Diſcourſe of the Variation of the Compaſs.—In 1594, Capt. John Davis publiſhed a ſmall treatiſe, entitled the Seaman's Secrets, which was much eſteemed in its time.

The writers of this period complained much of the errors of the plane chart, which continued ſtill in uſe, though they were unable to diſcover a proper remedy: till Gerrard Mercator contrived his Univerſal Map, which he publiſhed in 1569, without clearly underſtanding the principles of its conſtruction: theſe were firſt diſcovered by Mr. Edward Wright, who ſent an account of the true method of dividiag the meridian from Cambridge, where he was a Fellow, to Mr. Blundeville, with a ſhort table for that purpoſe, and a ſpecimen of a chart ſo divided. Theſe were publiſhed by Blundeville in 1594, among his Exerciſes; to the later editions of which was added his Diſcourſe of Univerſal Maps, firſt printed in 1589. However, in 1599 Mr. Wright printed his Correction of certain Errors in Navigation, in which work he ſhews the reaſon of this diviſion, the manner of conſtructing his table, and its uſes in Navigation. A ſecond edition of this treatiſe, with farther improvements, was printed in 1610, and a third edition by Mr. Moxon, in 1657.—The Method of Approximation, by what is called the middle latitude, now uſed by our ſailors, occurs in Gunter's works, firſt printed in 1623.—About this time Logarithms began to be introduced, which were applied to Navigation in a variety of ways by Mr. Edmund Gunter; though the firſt application of the Logarithmic Tables to the Caſes of Sailing, was by Mr. Thomas Addiſon, in his Arithmetical Navigation, printed in 1625.—In 1635 Mr. Henry Gellibrand printed a Diſcourſe Mathematical on the Variation of the Magnetical Needle, containing his diſcovery of the changes to which the variation is ſubject.—In 1631, Mr. Richard Norwood publiſhed an excellent Treatiſe of Trigonometry, adapted to the invention of logarithms, particularly in applying Napier's general canons; and for the farther improvement of Navigation, he undertook the laborious work of meaſuring a degree of the meridian, for examining the diviſions of the log-line. He has given a full and clear account of this operation in his Seaman's Practice, firſt publiſhed in 1637; where he alſo deſcribes his own excellent method of ſetting down and perfecting a ſea-reckoning, &c. This treatiſe, and that of Trigonometry, were often reprinted, as the principal books for learning ſcientifically the art of Navigation. What he had delivered, eſpecially in the latter of them, concerning this ſubject, was contracted as a manual for ſailors in a very ſmall piece, called his Epitome, which has gone through a great number of editions.—About the year 1645, Mr. Bond publiſhed, in Norwood's Epitome, a very great improvement in Wright's method, by a property in his meridian line, by which its diviſions are more ſcientifically aſſigned than the author was able to effect; which he deduced from this theorem, that theſe diviſions are analogous to the exceſſes of the logarithmic tangents of half the reſpective latitudes increaſed by 45 degrees, above the logarithm of the radius: this he afterwards explained more fully in the 3d edition of Gunter's works, printed in 1653; and the demonſtration of the general theorem was ſupplied by Mr. James Gregory of Aberdeen, in his Exercitationes Geometricæ, printed at London in 1668, and afterwards by Dr. Halley, in the Philoſ. Tranſ. numb. 219, as alſo by Mr. Cotes, numb. 388.—In 1700, Mr. Bond, who imagined that he had diſcovered the longitude, by having diſcovered the true theory of the magnetic variation, publiſhed a general map, on which curve lines were drawn, expreſſing the paths or places where the magnetic needle had the ſame variation. The poſitions of theſe curves will indeed continually ſuffer alterations; and therefore they ſhould be corrected from time to time, as they have already been for the years 1744, and 1756, by Mr. William Mountaine, and Mr. James Dodſon.—The allowances proper to be made for lee-way, are very particularly ſet down by Mr. John Buckler, and publiſhed in a ſmall tract firſt printed in 1702, intitled a New Compendium of the whole Art of Navigation, written by Mr. William Jones.

As it is now generally agreed that the earth is a ſpheroid, whoſe axis or polar diameter is ſhorter than the equatorial diameter, Dr. Murdoch publiſhed a tract in 1741, in which he adapted Wright's, or Mercator's ſailing to ſuch a figure; and in the ſame year Mr. Maclaurin alſo, in the Philoſ. Tranſ. numb. 461, for determining the meridional parts of a ſpheroid; and he has farther proſecuted the ſame ſpeculation in his Fluxions, printed in 1742.

The method of finding the longitude at ſea, by the obſerved diſtances of the moon from the ſun and ſtars, commonly called the Lunar method, was propoſed at an early ſtage in the Art of Navigation, and has now been happily carried into effectual execution by the encouragement of the Board of Longitude, which was eſtabliſhed in England in the year 1714, for rewarding any ſucceſsful endeavours to keep the longitude at ſea. In the year 1767, this Board publiſhed a Nautical Almanac, which has been continued annually ever ſince, by the advice, and under the direction of the aſtronomer royal at Greenwich: this work is purpoſely adapted to the uſe of navigators in long voyages, and, among a great many uſeful articles, contains tables of the lunar

lunar diſtances accurately computed for every 3 hours in the year, for the purpoſe of comparing the diſtance thus known for any time, with the diſtance obſerved in an unknown place, from whence to compute the longitude of that place. Under the auſpices of this Board too, beſides giving encouragement to the authors of many uſeful tables and other works, which would otherwiſe have been loſt, time-keepers have been brought to a wonderful degree of perfection, by Mr. Harriſon, Mr. Arnold, and many other perſons, which have proved highly advantageous in keeping the time during long voyages at ſea, and thence giving the longitude.

Some of the other principal writers on Navigation are Bartholomew Creſcenti, of Rome, in 1607; Willebrord Snell, at Leyden, in 1624, his Typhis Batavus; Geo. Fournier, at Paris, 1633; John Baptiſt Riccioli, at Bologna, in 1661; Dechales, in 1674 and 1677; the Sieur Blondel St. Aubin, in 1671 and 1673; M. Daſſier, in 1683; M. Sauveur, in 1692; M. John Bouguer, in 1698; F. Pezenas, in 1733 and 1741; and M. Peter Bouguer, who, in 1753, publiſhed a very elaborate treatiſe on this ſubject, intitled, Nouveau Traité de Navigation; in which he gives a variation compaſs of his own invention, and attempts to reform the Log, as he had before done in the Memoirs of the Academy of Sciences for 1747. He is alſo very particular in determining the lunations more accurately than by the common methods, and in deſcribing the corrections of the dead reckoning. This book was abridged and improved by M. de la Caille, in 1760. To theſe may be added the Navigation of Don George Juan of Spain, in 1757. And, in our own nation, the ſeveral treatiſes of Meſſieurs Newhouſe, Seller, Hodgſon, Atkinſon, Harris, Patoun, Hauxley, Wilſon, Moore, Nicholſon, &c; but, over all, The Elements of Navigation, in 2 vols, by Mr. John Robertſon, firſt printed about the year 1750, and ſince often re-printed; which is the moſt complete work of the kind extant; and to which work is prefixed a Diſſertation on the Riſe and Progreſs of the modern Art of Navigation, by Dr. James Wilſon, containing a very learned and elaborate hiſtory of the writings and improvements in this art.

For an account of the ſeveral inſtruments uſed in this art, with the methods for the longitude, and the various kinds and methods of Navigation, &c, ſee the reſpective articles themſelves.

NAVIGATION is either Proper or Common.

NAVIGATION, *Common*, uſually called Coaſting, in which the places are at no great diſtance from one another, and the ſhip ſails uſually in ſight of land, and moſtly within ſoundings. In this, little elſe is required beſides an acquaintance with the lands, the compaſs, and ſounding-line; each of which, ſee in its place.

NAVIGATION, *Proper*, is where the voyage is long, and purſued through the main ocean. And here, beſides the requiſites in the former caſe, are likewiſe required the uſe of Mercator's Chart, the azimuth and amplitude compaſſes, the log-line, and other inſtruments for celeſtial obſervations; as foreſtaffs, quadrants, and other ſectors, &c.

Navigation turns chiefly upon four things; two of which being given or known, the reſt are thence eaſily found out. Theſe four things are, the difference of latitude, difference of longitude, the reckoning or diſtance run, and the courſe or rhumb ſailed on. The latitudes are eaſily found, and that with ſufficient accuracy: the courſe and diſtance are had by the log-line, or dead reckoning, together with the compaſs. Nor is there any thing wanting to the perfection of Navigation, but to determine the longitude. The mathematicians and aſtronomers of many ages have applied themſelves, with great aſſiduity, to ſupply this grand deſideratum, but not altogether with the ſucceſs that was deſired, conſidering the importance of the object, and the magnificent rewards offered by ſeveral ſtates to the diſcoverer. See LONGITUDE.

Sub-Marine NAVIGATION, or the art of ſailing under water, is mentioned by Mr. Boyle, as the deſideratum of the art of Navigation. This, he ſays, was ſucceſsfully attempted, by Cornelius Drebbel; ſeveral perſons who were in the boat breathing freely all the time. See DIVING-*bell*.

Inland NAVIGATION, is that performed by ſmall craft, upon canals &c, cut through a country.

NAVIGATOR, a perſon capable of conducting a ſhip at ſea to any place propoſed.

NAUTICAL *Chart*, the ſame as Sea-Chart.

NAUTICAL *Compaſs*, the ſame as Sea-Compaſs.

NAUTICAL *Planiſphere*, a projection or conſtruction of the terreſtrial globe upon a plane, for the uſe of mariners; ſuch as the Plane Chart, and Mercator's Chart.

NEAP, or NEEP-*Tides*, are thoſe that happen at equal diſtances between the ſpring tides. The Neap tides are the loweſt, as the ſpring tides are the higheſt ones, being the oppoſites to them. And as the higheſt of the ſpring tides happens about three days after the full or change of the moon, ſo the loweſt of the Neap tides fall about three days after the quarters, or four days before the full and change; when the ſeamen ſay it is Deep Neap.

NEAPED. When a ſhip wants water, ſo that ſhe cannot get out of the harbour, out of the dock, or off the ground, the ſeamen ſay, ſhe is Neaped, or Beneaped.

NEBULOUS, or Cloudy, a term applied to certain fixed ſtars, which ſhew a dim, hazy light; being leſs than thoſe of the 6th magnitude, and therefore ſcarcely viſible to the naked eye, to which at beſt they only appear like little duſky ſpecks or clouds.

Through a moderate teleſcope, theſe Nebulous ſtars plainly appear to be congeries or cluſters of ſeveral little ſtars. In the Nebulous ſtar called Præſepe, in the breaſt of Cancer, there are reckoned 36 little ſtars, 3 of which Mr. Flamſteed ſets down in his catalogue. In the Nebulous ſtar of Orion, are reckoned 21. F. le Compte adds, that there are 40 in the Pleiades; 12 in the ſtar in the middle of Orion's ſword; 500 in the extent of two degrees of the ſame conſtellation; and 2500 in the whole conſtellation. It may farther be obſerved, that the galaxy, or milky-way, is a continued aſſemblage of Nebulæ, or vaſt cluſters of ſmall ſtars.

NEEDHAM (JOHN TUBERVILLE), a reſpectable philoſopher and catholic divine, was born at London December 10, 1713. His father poſſeſſed a conſider-

able

able patrimony at Hilſton, in the county of Monmouth, being of the younger or catholic branch of the Needham family, and who died young, leaving but a ſmall fortune to his four children. Our author, who was the eldeſt ſon, ſtudied in the Engliſh college of Douai, where he took orders, taught rhetoric for ſeveral years, and ſurpaſſed all the other profeſſors of that ſeminary in the knowledge of experimental philoſophy.

In 1740, he was engaged by his ſuperiors in the ſervice of the Engliſh miſſion, and was entruſted with the direction of the ſchool erected at Twyford, near Wincheſter, for the education of the Roman Catholic youth. —In 1744 he was appointed profeſſor of philoſophy in the Engliſh college at Liſbon, where, on account of his bad health, he remained only 15 months. After his return, he paſſed ſeveral years at London and Paris, which were chiefly employed in microſcopical obſervations, and in other branches of experimental philoſophy. The reſults of theſe obſervations and experiments were publiſhed in the Philoſophical Tranſactions of the Royal Society of London in the year 1749, and in a volume in 12mo at Paris in 1750; and an account of them was alſo given by M. Buffon, in the firſt volumes of his natural hiſtory. There was an intimate connection ſubſiſted between Mr. Needham and this illuſtrious French naturaliſt: they made their experiments and obſervations together; though the reſults and ſyſtems which they deduced from the ſame objects and operations were totally different.

Mr. Needham was elected a member of the Royal Society of London in the year 1747, and of the Antiquarian Society ſome time after.—From the year 1751 to 1767 he was chiefly employed in finiſhing the education of ſeveral Engliſh and Iriſh noblemen, by attending them as tutor in their travels through France, Italy, and other countries. He then retired from this wandering life to the Engliſh ſeminary at Paris, and in 1768 was choſen by the Royal Academy of Sciences in that city a correſponding member.

When the regency of the Auſtrian Netherlands, for the revival of philoſophy and literature in that country, formed the project of an Imperial Academy, which was preceded by the erection of a ſmall literary ſociety to prepare the way for its execution, Mr. Needham was invited to Bruſſels, and was appointed ſucceſſively chief director of both theſe foundations; an appointment which he held, together with ſome eccleſiaſtical preferments in the Low Countries, till his death, which happened December the 30th 1781.

Mr. Needham's papers inſerted in the Philoſophical Tranſactions, were the following, viz:

1. Account of Chalky Tubulous Concretions, called Malm: vol. 42.
2. Microſcopical Obſervations on Worms in Smutty Corn: vol. 42.
3. Electrical Experiments lately made at Paris: vol. 44.
4. Account of M. Buffon's Mirror, which burns at 66 feet: ib.
5. Obſervations upon the Generation, Compoſition, and Decompoſition of Animal and Vegetable Subſtances: vol. 45.
6. On the Diſcovery of Aſbeſtos in France: vol. 51.

Other works printed at Paris, in French, are,

1. New Microſcopical Diſcoveries: 1745.
2. The ſame enlarged: 1750.
3. On Microſcopical, and the Generation of Organized Bodies: 2 vols, 1769.

NEEDLE, *Magnetical*, denotes a Needle, or a ſlender piece of iron or ſteel, touched with a loadſtone; which, when ſuſtained on a pivot or centre, upon which it plays round at liberty, it ſettles at length in a certain direction, either duly, or nearly north-and-ſouth, and called the magnetic meridian.

Magnetical Needles are of two kinds; Horizontal and Inclinatory.

Horizontal NEEDLES, are thoſe equally balanced on each ſide of the pivot which ſuſtains them; and which, playing horizontally, with their two extremes point out the north and ſouth parts of the horizon.

Conſtruction of a Horizontal NEEDLE. Having procured a thin light piece of pure ſteel, about 6 inches long, a perforation is made in the middle, over which a braſs cap is ſoldered on, having its inner cavity conical, ſo as to play freely on the ſtyle or pivot, which has a fine ſteel point. To give the Needle its verticity, or directive faculty, it is rubbed or ſtroked leiſurely on each pole of a magnet, from the ſouth pole towards the north; firſt beginning with the northern end, and going back at each repeated ſtroke towards the ſouth; being careful not to give a ſtroke in a contrary direction, which would take away the power again. Alſo the hand ſhould not return directly back again the ſame way it came, but ſhould return in a kind of oval figure, carrying the hand about 6 or 8 inches beyond the point where the touch ended, but not beyond on the ſide where the touch begins.

Before touching, the north end of the Needle, in our hemiſphere, is made a little lighter than the other end; becauſe the touch always deſtroys an exact balance, rendering the north end heavier than the ſouth, and thus cauſing the Needle to dip. And if, after touching, the Needle be out of its equilibrium, ſomething muſt be filed off from the heavier ſide, till it be found to balance evenly.

Needles may alſo acquire the magnetic virtue by means of artificial magnetic bars in the following manner: Lay two equal Needles parallel and about an inch aſunder, with the north end of one and the ſouth end of the other pointing the ſame way, and apply two conductors in contact with their ends: then, with two magnetic hard bars, one in each hand, and held as nearly horizontal as can be, with the upper ends, of contrary names, turned outwards to the right and left, let a Needle be ſtroked or rubbed from the middle to both ends at the ſame time, for ten or twelve times, the north end of a bar going over the ſouth end of a Needle, and the ſouth end of a bar going over the north end of a Needle: then, without moving from the place, change hands with the bars, or in the ſame hands turn the other ends downwards, and ſtroke the other Needle in like manner; ſo will they both be magnetical. But to make them ſtill ſtronger, repeat the operation three or four times from Needle to Needle, and

at laſt turn the lower ſide of each Needle upwards, and repeat the operations of ſtroking them, as on the former ſides.

The Needles that were formerly applied to the compaſs, on board merchant ſhips, were formed of two pieces of ſteel wire, each being bent in the middle, ſo as to form an obtuſe angle, while their ends, being applied together, made an acute one, ſo that the whole repreſented the form of a lozenge. Dr. Knight, who has ſo much improved the compaſs, found, by repeated experiments, that partly from the foregoing ſtructure, and partly from the unequal hardening of the ends, theſe Needles not only varied from the true direction, but from one another, and from themſelves.

Alſo the Needles formerly uſed on board the men of war, and ſome of the larger trading ſhips, were made of one piece of ſteel, of a ſpring temper, and broad towards the ends, but tapering towards the middle. Every Needle of this form is found to have ſix poles inſtead of two, one at each end, two where it becomes tapering, and two at the hole in the middle.

To remedy theſe errors and inconveniences, the Needle which Dr. Knight contrived for his compaſs, is a ſlender parallelopipedon, being quite ſtraight and ſquare at the ends, and ſo has only two poles, although the curves are a little confuſed about the hole in the middle; though it is, upon the whole, the ſimpleſt and beſt.

Mr. Michell ſuggeſts, that it would be uſeful to increaſe the weight and length of magnetic Needles, which would render them both more accurate and permanent; alſo to cover them with a coat of linſeed oil, or varniſh, to preſerve them from any ruſt.

A Needle on occaſion may be prepared without touching it on a loadſtone: for a fine ſteel ſewing Needle, gently laid on the water, or delicately ſuſpended in the air, will take the north-and-ſouth direction.—Thus alſo a Needle heated in the fire, and cooled again in the direction of the meridian, or only in an erect poſition, acquires the ſame faculty.

Declination or Variation of the NEEDLE, is the deviation of the horizontal Needle from the meridian; or the angle it makes with the meridian, when freely ſuſpended in an horizontal plane.

A Needle is always changing the line of its direction, traverſing ſlowly to certain limits towards the eaſt and weſt ſides of the meridian. It was at firſt thought that the magnetic Needle pointed due north; but it was obſerved by Cabot and Columbus that it had a deviation from the north, though they did not ſuſpect that this deviation had itſelf a variation, and was continually changing. This change in the Variation was firſt found out, according to Bond, by Mr. John Mair, ſecondly by Mr. Gunter, and thirdly by Mr. Gellibrand, by comparing together the obſervations made at different times near the ſame place by Mr. Burrowes, Mr. Gunter, and himſelf, and he publiſhed a Diſcourſe upon it in 1635. Soon after this, Mr. Bond ventured to deliver the rate at which the Variation changes for ſeveral years; by which he foretold that at London in 1657 there would be no Variation of the compaſs, and from that time it would gradually increaſe the other way, or towards the weſt, making certain revolutions; which happened accordingly: and upon this Variation he propoſed a method of finding the longitude, which has been farther improved by many others ſince his time, though with very little ſucceſs. See VARIATION.

The period or revolution of the Variation, Henry Philips made only 370 years, but according to Henry Bond it is 600 years, and their yearly motion 36 minutes. The firſt good obſervations of the Variation were by Burrowes, about the year 1580, when the Variation at London was 11° 15′ eaſt; and ſince that time the Needle has been moving to the weſtward at that place; alſo by the obſervations of different perſons, it has been found to point, at different times, as below:

Years.	*Obſervers.*	*Variat. E. or W.*
1580	Burrowes	11° 15′ Eaſt.
1622	Gunter	5 56
1634	Gellibrand	4 3
1640	Bond	3 7
1657	Bond	0 0
1665	Bond	1 23 Weſt.
1666	Bond	1 36
1672	-	2 30
1683	-	4 30
1692	-	6 00
1723	Graham	14 17
1747	-	17 40
1774	Royal Society	21 16
1775	Royal Society	21 43
1776	Royal Society	21 47
1777	Royal Society	22 12
1778	Royal Society	22 20
1779	Royal Society	22 28
1780	Royal Society	22 41

By this Table it appears that, from the firſt obſervations in 1580 till 1657, the change in the Variation was 11° 15′ in 77 years, which is at the rate nearly of 9′ a year; and from 1657 till 1780, or the ſpace of 123 years, it changed 22° 41′, which is at the rate of 11′ a year nearly; which it may be preſumed is very near the truth.

The Variation and Dip of the Needle was for many years carefully obſerved by the Royal Society while they met at Crane Court; and it is a pity that ſuch obſervations have not been continued ſince that time.

Dipping, or *Inclinatory* NEEDLE, is a Needle to ſhew the Dip of the Magnetic Needle, or how far it points below the horizon.

The Inclination or Dip of the Needle was firſt obſerved by Robert Norman, a compaſs-maker at Ratcliffe; and according to him, the dip at that place, in the year 1576, was 71° 50′; and at the Royal Society it was obſerved for ſome years lately as follows:

viz in	1776	72° 30′
	1778	72 25
	1780	72 17.

Mr. Henry Bond makes the Variation and Dip of the Needle depend on the ſame motion of the magnetic poles in their revolution, and upon it he founded a method of diſcovering the longitude at ſea.

NEEP *Tides*. See NEAP *Tides*.

NEGATIVE, in Algebra, ſomething marked with the ſign —, or minus, as being contrary to ſuch as are poſitive, or marked with the ſign plus +. As Negative powers and roots, Negative quantities, &c. See POWER, ROOT, QUANTITY, &c.

NEGATIVE *Sign*, the ſign of ſubtraction —, or that which denotes ſomething in defect. Stifel is the firſt author I find who uſed this mark — for ſubtraction, or negation; before his time, the word minus itſelf was uſed, or elſe its initial *m*.

The uſe of the Negative ſign in algebra, is attended with ſeveral conſequences that at firſt ſight are admitted with ſome difficulty, and has ſometimes given occaſion to notions that ſeem to have no real foundation. This ſign implies, that the real value of the quantity repreſented by the letter to which it is prefixed, is to be ſubtracted; and it ſerves, with the poſitive ſign, to keep in view what elements or parts enter into the compoſition of quantities, and in what manner, whether as increments or decrements, that is whether by addition or ſubtraction, which is of the greateſt uſe in this art.

Hence it ſerves to expreſs a quantity of an oppoſite quality to a poſitive; ſuch as a line in a contrary poſition, a motion with oppoſite direction, or a centrifugal force in oppoſition to gravity; and thus it often ſaves the trouble of diſtinguiſhing, and demonſtrating ſeparately, the various caſes of proportions, and preſerves their analogy in view. But as the proportions of lines depend on their magnitude only, without regard to their poſition; and motions and forces are ſaid to be equal or unequal, in any given ratio, without regard to their directions; and in general the proportion of quantities relates to their magnitude only, without determining whether they are to be conſidered as increments or decrements; ſo there is no ground to imagine any other proportion of + *a* and — *b*, than that of the real magnitudes of the quantities repreſented by *a* and *b*, whether theſe quantities are, in any particular caſe, to be added or ſubtracted.

As to the uſual arithmetical operations of addition, ſubtraction, &c, the caſe is different, as the effect of the Negative ſign is here to be carefully attended to, and is to be conſidered always as producing, in thoſe operations, an effect juſt oppoſite to the poſitive ſign. Thus, it is the ſame thing to ſubtract a decrement as to add an equal increment, or to ſubtract — *b* from *a* — *b*, is to add + *b* to it: and becauſe multiplying a quantity by a Negative number, implies only a repeated ſubtraction of it, the multiplying — *b* by — *n*, is ſubtracting — *b* as often as there are units in *n*, and is therefore equivalent to adding + *b* ſo many times, or the ſame as adding + *nb*. But if we infer from this, that 1 is to — *n* as — *b* to *nb*, according to the rule, that unit is to one of the factors as the other factor is to the product, there is not ground to imagine that there is any myſtery in this, or any other meaning than that the real quantities repreſented by 1, *n*, *b*, and *nb* are proportional. For that rule relates only to the magnitude of the factors and product, without determining whether any factor, or the product, is additive or ſubtractive. But this likewiſe muſt be determined in algebraic computations; and this is the proper uſe concerning the ſigns, without which the operation could not proceed. Becauſe a quantity to be ſubtracted is never produced, in compoſition, by any repeated addition of a poſitive, or repeated ſubtraction of a Negative, a Negative ſquare number is never produced by compoſition from a root. Hence the $\sqrt{-1}$, or the ſquare root of a Negative, implies an imaginary quantity, and in reſolution is a mark or character of the impoſſible caſes of a problem, unleſs it is compenſated by another imaginary ſymbol or ſuppoſition, for then the whole expreſſion may have a real ſignification. Thus $1 + \sqrt{-1}$, and $1 - \sqrt{-1}$, taken ſeparately, are both imaginary, but yet their ſum is the number 2: as the conditions that ſeparately would render the ſolution of a problem impoſſible, in ſome caſes deſtroy each others effect when conjoined. In the purſuit of general concluſions, and of ſimple forms for repreſenting them, expreſſions of this kind muſt ſometimes ariſe, where the imaginary ſymbol is compenſated in a manner that is not always ſo obvious.

By proper ſubſtitutions, however, the expreſſion may be transformed into another, wherein each particular term may have a real ſignification, as well as the whole expreſſion.

The theorems that are ſometimes briefly diſcovered by the uſe of this ſymbol, may be demonſtrated without it by the inverſe operation, or ſome other way; and though ſuch ſymbols are of ſome uſe in the computations in the method of fluxions, &c, its evidence cannot be ſaid to depend upon any arts of this kind. See Maclaurin's Fluxions, book 2, chap. 1.

Mr. Baron Maſeres publiſhed a pretty large book in quarto, on the uſe of the Negative Sign in algebra.

For the rules or ways of uſing the Negative ſign in the ſeveral rules of Algebra, ſee thoſe rules ſeverally, viz, ADDITION, SUBTRACTION, MULTIPLICATION, &c. And for the method of managing the roots of Negative quantities, ſee IMPOSSIBLES.

NEWEL, the upright poſt that ſtairs turn about; being that part of the ſtaircaſe which ſuſtains the ſteps.

NEWTON (Dr. JOHN), an eminent Engliſh mathematician and divine, was the grandſon of John Newton of Axmouth in Devonſhire, and ſon of Humphrey Newton of Oundle in Northamptonſhire, where he was born in 1622. After receiving the proper foundation of a grammar education, he was ſent to Oxford, where he was entered a commoner of St. Edmund's Hall in 1637. He took the degree of bachelor of arts in 1641; and the year following he was created maſter, in precedence to many ſtudents of quality, on account of his diſtinguiſhed talents in the great branches of literature. His genius leading him ſtrongly to aſtronomy and mathematics, he applied himſelf diligently to thoſe ſciences, as well as to divinity, and made a great proficiency in them, which he found of ſome ſervice to him during Cromwell's government.

After the reſtoration of Charles the 2d, he reaped the fruits of his loyalty: being created doctor of divinity at Oxford, Sept. 1661, he was made one of the king's chaplains, and rector of Roſs in Herefordſhire, inſtead of Mr. John Toombes, ejected for nonconformity. He held this living till his death, which happened at Roſs on Chriſtmas day 1678, at 56 years of age.

Mr. Wood gave him the character of a capricious and humourſome perſon. However that be, his writings are a proof of his great application to ſtudy, and a ſufficient monument of his genius and ſkill in the mathematical ſciences. Theſe are,

1. Aſtronomia Britannica, &c: in 4to, 1656.
2. Help to Calculation; with Tables of Declination, &c: 4to, 1657.
3. Trigonometria Britannica, in two books; the one compoſed by our author, and the other tranſlated from the Latin of Henry Gellibrand: folio, 1658.
4. Chiliades Centum Logarithmorum, printed with,
5. Geometrical Trigonometry: 1659.
6. Mathematical Elements, three parts: 4to, 1660.
7. A Perpetual Diary, or Almanac: 1662.
8. Deſcription of the Uſe of the Carpenter's Rule: 1667.
9. Ephemerides, ſhewing the intereſt and rate of money at 6 per cent. &c: 1667.
10. Chiliades Centum Logarithmorum et Tabula Partium Proportionalium: 1667.
11. The Rule of Intereſt, or the Caſe of Decimal Fractions, &c, part 2: 8vo, 1668.
12. School-paſtimes for young children, &c: 8vo, 1669.
13. Art of Practical Gauging, &c: 1669.
14. Introduction to the art of Rhetoric: 1671.
15. The Art of Natural Arithmetic in Whole Numbers, and Fractions Vulgar and Decimal: 8vo, 1671.
16. The Engliſh Academy: 8vo, 1677.
17. Coſmography.
18. Introduction to Aſtronomy.
19. Introduction to Geography: 8vo, 1678.

NEWTON (Sir ISAAC), one of the greateſt philoſophers and mathematicians the world has produced, was born at Woolſtrop in Lincolnſhire on Chriſtmas day 1642. He was deſcended from the eldeſt branch of the family of Sir John Newton, bart. who were lords of the manor of Woolſtrop, and had been poſſeſſed of the eſtate for about two centuries before; to which they had removed from Weſtley in the ſame county, but originally they came from the town of Newton in Lancaſhire. Other accounts ſay, I think more truly, that he was the only child of Mr. John Newton of Coleſworth, near Grantham in Lincolnſhire, who had there an eſtate of about 120l. a year, which he kept in his own hands. His mother was of the ancient and opulent family of the Ayſcoughs, or Aſkews, of the ſame county. Our author loſing his father while he was very young, the care of his education devolved on his mother, who, though ſhe married again after his father's death, did not neglect to improve by a liberal education the promiſing genius that was obſerved in her ſon. At 12 years of age, by the advice of his maternal uncle, he was ſent to the grammar ſchool at Grantham, where he made a good proficiency in the languages, and laid the foundation of his future ſtudies. Even here was obſerved in him a ſtrong inclination to figures and philoſophical ſubjects. One trait of this early diſpoſition is told of him: he had then a rude method of meaſuring the force of the wind blowing againſt him, by obſerving how much farther he could leap in the direction of the wind, or blowing on his back, than he could leap the contrary way, or oppoſed to the wind: an early mark of his original infantine genius.

After a few years ſpent here, his mother took him home; intending, as ſhe had no other child, to have the pleaſure of his company; and that, after the manner of his father before him, he ſhould occupy his own eſtate.

But inſtead of minding the markets, or the buſineſs of the farm, he was always ſtudying and poring over his books, even by ſtealth, from his mother's knowledge. On one of theſe occaſions his uncle diſcovered him one day in a hay-loft at Grantham, whither he had been ſent to the market, working a mathematical problem; and having otherwiſe obſerved the boy's mind to be uncommonly bent upon learning, he prevailed upon his ſiſter to part with him; and he was accordingly ſent, in 1660, to Trinity College in Cambridge, where his uncle, having himſelf been a member of it, had ſtill many friends. Iſaac was ſoon taken notice of by Dr. Barrow, who was ſoon after appointed the firſt Lucaſian profeſſor of mathematics; and obſerving his bright genius, contracted a great friendſhip for him. At his outſetting here, Euclid was firſt put into his hands, as uſual, but that author was ſoon diſmiſſed; ſeeming to him too plain and eaſy, and unworthy of taking up his time. He underſtood him almoſt before he read him; and a caſt of his eye upon the contents of his theorems, was ſufficient to make him maſter of them: and as the analytical method of Des Cartes was then much in vogue, he particularly applied to it, and Kepler's Optics, &c, making ſeveral improvements on them, which he entered upon the margins of the books as he went on, as his cuſtom was in ſtudying any author.

Thus he was employed till the year 1664, when he opened a way into his new method of Fluxions and Infinite Series; and the ſame year took the degree of bachelor of arts. In the mean time, obſerving that the mathematicians were much engaged in the buſineſs of improving teleſcopes, by grinding glaſſes into one of the figures made by the three ſections of a cone, upon the principle then generally entertained, that light was homogeneous, he ſet himſelf to grinding of optic glaſſes, of other figures than ſpherical, having as yet no diſtruſt of the homogeneous nature of light: but not hitting preſently upon any thing in this attempt to ſatisfy his mind, he procured a glaſs priſm, that he might try the celebrated phenomena of colours, diſcovered by Grimaldi not long before. He was much pleaſed at firſt with the vivid brightneſs of the colours produced by this experiment; but after a while, conſidering them in a philoſophical way, with that circumſpection which was natural to him, he was ſurpriſed to ſee them in an oblong form, which, according to the received rule of refractions, ought to be circular. At firſt he thought the irregularity might poſſibly be no more than accidental; but this was what he could not leave without further enquiry: accordingly, he ſoon invented an infallible method of deciding the queſtion, and the reſult was, his *New Theory of Light and Colours*.

However, the theory alone, unexpected and ſurpriſing as it was, did not ſatisfy him; he rather conſidered

the proper uſe that might be made of it for improving teleſcopes, which was his firſt deſign. To this end, having now diſcovered that light was not homogeneous, but an heterogeneous mixture of differently refrangible rays, he computed the errors ariſing from this different refrangibility; and, finding them to exceed ſome hundreds of times thoſe occaſioned by the circular figure of the glaſſes, he threw aſide his glaſs works, and took reflections into conſideration. He was now ſenſible that optical inſtruments might be brought to any degree of perfection deſired, in caſe there could be found a reflecting ſubſtance which would poliſh as finely as glaſs, and reflect as much light as glaſs tranſmits, and the art of giving it a parabolical figure he alſo attained: but theſe ſeemed to him very great difficulties; nay, he almoſt thought them inſuperable, when he further conſidered, that every irregularity in a reflecting ſuperficies makes the rays ſtray five or ſix times more from their due courſe, than the like irregularities in a refracting one.

Amidſt theſe ſpeculations, he was forced from Cambridge, in 1665, by the plague; and it was more than two years before he made any further progreſs in the ſubject. However, he was far from paſſing his time idly in the country; on the contrary, it was here, at this time, that he firſt ſtarted the hint that gave riſe to the ſyſtem of the world, which is the main ſubject of the *Principia*. In his retirement, he was ſitting alone in a garden, when ſome apples falling from a tree, led his thoughts upon the ſubject of gravity; and, reflecting on the power of that principle, he began to conſider, that, as this power is not found to be ſenſibly diminiſhed at the remoteſt diſtance from the centre of the earth to which we can riſe, neither at the tops of the loftieſt buildings, nor on the ſummits of the higheſt mountains, it appeared to him reaſonable to conclude, that this power muſt extend much farther than is uſually thought. "Why not as high as the moon? ſaid he to himſelf; and if ſo, her motion muſt be influenced by it; perhaps ſhe is retained in her orbit by it: however, though the power of gravity is not ſenſibly weakened in the little change of diſtance at which we can place ourſelves from the centre of the earth, yet it is very poſſible that, at the height of the moon, this power may differ in ſtrength much from what it is here." To make an eſtimate what might be the degree of this diminution, he conſidered with himſelf, that if the moon be retained in her orbit by the force of gravity, no doubt the primary planets are carried about the ſun by the like power; and, by comparing the periods of the ſeveral planets with their diſtances from the ſun, he found, that if any power like gravity held them in their courſes, its ſtrength muſt decreaſe in the duplicate proportion of the increaſe of diſtance. This he concluded, by ſuppoſing them to move in perfect circles, concentric to the ſun, from which the orbits of the greateſt part of them do not much differ. Suppoſing therefore the force of gravity, when extended to the moon, to decreaſe in the ſame manner, he computed whether that force would be ſufficient to keep the moon in her orbit.

In this computation, being abſent from books, he took the common eſtimate in uſe among the geographers and our ſeamen, before Norwood had meaſured the earth, namely that 60 miles make one degree of latitude; but as that is a very erroneous ſuppoſition, each degree containing about 69½ of our Engliſh miles, his computation upon it did not make the power of gravity, decreaſing in a duplicate proportion to the diſtance, anſwerable to the power which retained the moon in her orbit: whence he concluded, that ſome other cauſe muſt at leaſt join with the action of the power of gravity on the moon. For this reaſon he laid aſide, for that time, any further thoughts upon the matter. Mr. Whiſton (in his Memoirs, pa. 33) ſays, he told him that he thought Des Cartes's vortices might concur with the action of gravity.

Nor did he reſume this enquiry on his return to Cambridge, which was ſhortly after. The truth is, his thoughts were now engaged upon his newly projected reflecting teleſcope, of which he made a ſmall ſpecimen, with a metallic reflector ſpherically concave. It was but a rude eſſay, chiefly defective by the want of a good poliſh for the metal. This inſtrument is now in the poſſeſſion of the Royal Society. In 1667 he was choſen Fellow of his college, and took the degree of maſter of arts. And in 1669 Dr. Barrow reſigned to him the mathematical chair at Cambridge, the buſineſs of which appointment interrupted for a while his attention to the teleſcope: however, as his thoughts had been for ſome time chiefly employed upon optics, he made his diſcoveries in that ſcience the ſubject of his lectures, for the firſt three years after he was appointed Mathematical Profeſſor: and having now brought his *Theory of Light and Colours* to a conſiderable degree of perfection, and having been elected a Fellow of the Royal Society in Jan. 1672, he communicated it to that body, to have their judgment upon it; and it was afterwards publiſhed in their Tranſactions, viz, of Feb. 19, 1672. This publication occaſioned a diſpute upon the truth of it, which gave him ſo much uneaſineſs, that he reſolved not to publiſh any thing further for a while upon the ſubject; and in that reſolution he laid up his *Optical Lectures*, although he had prepared them for the preſs. And the *Analyſis by Infinite Series*, which he had intended to ſubjoin to them, unhappily for the world, underwent the ſame fate, and for the ſame reaſon.

In this temper he reſumed his teleſcope; and obſerving that there was no abſolute neceſſity for the parabolic figure of the glaſſes, ſince, if metals could be ground truly ſpherical, they would be able to bear as great apertures as men could give a poliſh to, he completed another inſtrument of the ſame kind. This anſwering the purpoſe ſo well, as, though only half a foot in length, to ſhew the planet Jupiter diſtinctly round, with his four ſatellites, and alſo Venus horned, he ſent it to the Royal Society, at their requeſt, together with a deſcription of it, with further particulars; which were publiſhed in the Philoſophical Tranſactions for March 1672. Several attempts were alſo made by that ſociety to bring it to perfection; but, for want of a proper compoſition of metal, and a good poliſh, nothing ſucceeded, and the invention lay dormant, till Hadley made his Newtonian teleſcope in 1723. At the requeſt of Leibnitz, in 1676, he explained his invention of Infinite Series, and took notice how far he had improved it by his Method of Fluxions, which however he

he ſtill concealed, and particularly on this occaſion, by a tranſpoſition of the letters that make up the two fundamental propoſitions of it, into an alphabetical order; the letters concerning which are inſerted in Collins's Commercium Epiſtolicum, printed 1712. In the winter between the years 1676 and 1677, he found out the grand propoſition, that, by a centripetal force acting reciprocally as the ſquare of the diſtance, a planet muſt revolve in an ellipſis, about the centre of force placed in its lower focus, and, by a radius drawn to that centre, deſcribe areas proportional to the times. In 1680 he made ſeveral aſtronomical obſervations upon the comet that then appeared; which, for ſome conſiderable time, he took not to be one and the ſame, but two different comets; and upon this occaſion ſeveral letters paſſed between him and Mr. Flamſteed.

He was ſtill under this miſtake, when he received a letter from Dr. Hook, explaining the nature of the line deſcribed by a falling body, ſuppoſed to be moved circularly by the diurnal motion of the earth, and perpendicularly by the power of gravity. This letter put him upon enquiring anew what was the real figure in which ſuch a body moved; and that enquiry, convincing him of another miſtake which he had before fallen into concerning that figure, put him upon reſuming his former thoughts with regard to the moon; and Picart having not long before, viz, in 1679, meaſured a degree of the earth with ſufficient accuracy, by uſing his meaſures, that planet appeared to be retained in her orbit by the ſole power of gravity; and conſequently that this power decreaſes in the duplicate ratio of the diſtance; as he had formerly conjectured. Upon this principle, he found the line deſcribed by a falling body to be an ellipſis, having one focus in the centre of the earth. And finding by this means, that the primary planets really moved in ſuch orbits as Kepler had ſuppoſed, he had the ſatisfaction to ſee that this enquiry, which he had undertaken at firſt out of mere curioſity, could be applied to the greateſt purpoſes. Hereupon he drew up about a dozen propoſitions, relating to the motion of the primary planets round the ſun, which were communicated to the Royal Society in the latter end of 1683. This coming to be known to Dr. Halley, that gentleman, who had attempted the demonſtration in vain, applied, in Auguſt 1684, to Newton, who aſſured him that he had abſolutely completed the proof. This was alſo regiſtered in the books of the Royal Society; at whoſe earneſt ſolicitation Newton finiſhed the work, which was printed under the care of Dr. Halley, and came out about midſummer 1687, under the title of, *Philoſophiæ naturalis Principia mathematica*, containing in the third book, the Cometic Aſtronomy, which had been lately diſcovered by him, and now made its firſt appearance in the world: a work which may be looked upon as the production of a celeſtial intelligence rather than of a man.

This work however, in which the great author has built a new ſyſtem of natural philoſophy upon the moſt ſublime geometry, did not meet at firſt with all the applauſe it deſerved, and was one day to receive. Two reaſons concurred in producing this effect: Des Cartes had then got full poſſeſſion of the world. His philoſophy was indeed the creature of a fine imagination, gaily dreſſed out: he had given her likewiſe ſome of nature's fine features, and painted the reſt to a ſeeming likeneſs of her. On the other hand, Newton had with an unparalleled penetration, and force of genius, purſued nature up to her moſt ſecret abode, and was intent to demonſtrate her reſidence to others, rather than anxious to deſcribe particularly the way by which he arrived at it himſelf: he finiſhed his piece in that elegant conciſeneſs, which had juſtly gained the Ancients an univerſal eſteem. In fact, the conſequences flow with ſuch rapidity from the principles, that the reader is often left to ſupply a long chain of reaſoning to connect them: ſo that it required ſome time before the world could underſtand it. The beſt mathematicians were obliged to ſtudy it with care, before they could make themſelves maſter of it; and thoſe of a lower rank durſt not venture upon it, till encouraged by the teſtimonies of the more learned. But at laſt, when its value came to be ſufficiently known, the approbation which had been ſo ſlowly gained, became univerſal, and nothing was to be heard from all quarters, but one general burſt of admiration. "Does Mr. Newton eat, drink, or ſleep like other men?" ſays the marquis de l'Hoſpital, one of the greateſt mathematicians of the age, to the Engliſh who viſited him. "I repreſent him to myſelf as a celeſtial genius intirely diſengaged from matter."

In the midſt of theſe profound mathematical reſearches, juſt before his Principia went to the preſs in 1686, the privileges of the univerſity being attacked by James the 2d, Newton appeared among its moſt ſtrenuous defenders, and was on that occaſion appointed one of their delegates to the high-commiſſion court; and they made ſuch a defence, that James thought proper to drop the affair. Our author was alſo choſen one of their members for the Convention-Parliament in 1688, in which he ſat till it was diſſolved.

Newton's merit was well known to Mr. Montague, then chancellor of the exchequer, and afterwards earl of Halifax, who had been bred at the ſame college with him; and when he undertook the great work of recoining the money, he fixed his eye upon Newton for an aſſiſtant in it; and accordingly, in 1696, he was appointed warden of the mint, in which employment, he rendered very ſignal ſervice to the nation. And three years after he was promoted to be maſter of the mint, a place worth 12 or 15 hundred pounds per annum, which he held till his death. Upon this promotion, he appointed Mr. Whiſton his deputy in the mathematical profeſſorſhip at Cambridge, giving him the full profits of the place, which appointment itſelf he alſo procured for him in 1703. The ſame year our author was choſen preſident of the Royal Society, in which chair he ſat for 25 years, namely till the time of his death; and he had been choſen a member of the Royal Academy of Sciences at Paris in 1699, as ſoon as the new regulation was made for admitting foreigners into that ſociety.

Ever ſince the firſt diſcovery of the heterogeneous mixture of light, and the production of colours thence ariſing, he had employed a good part of his time in bringing the experiment, upon which the theory is founded, to a degree of exactneſs that might ſatisfy himſelf. The truth is, this ſeems to have been his favourite invention; 30 years he had ſpent in this ardu-

ous taſk, before he publiſhed it in 1704. In infinite ſeries and fluxions, and in the power and rule of gravity in preſerving the ſolar ſyſtem, there had been ſome, though diſtant hints, given by others before him: whereas in diſſecting a ray of light into its primary conſtituent particles, which then admitted of no further ſeparation; in the diſcovery of the different refrangibility of theſe particles thus ſeparated; and that theſe conſtituent rays had each its own peculiar colour inherent in it; that rays falling in the ſame angle of incidence have alternate fits of reflection and refraction; that bodies are rendered tranſparent by the minuteneſs of their pores, and become opaque by having them large; and that the moſt tranſparent body, by having a great thinneſs, will become leſs pervious to the light: in all theſe, which make up his new theory of light and colours, he was abſolutely and entirely the firſt ſtarter; and as the ſubject is of the moſt ſubtle and delicate nature, he thought it neceſſary to be himſelf the laſt finiſher of it.

In fact, the affair that chiefly employed his reſearches for ſo many years, was far from being confined to the ſubject of light alone. On the contrary, all that we know of natural bodies, ſeemed to be comprehended in it; he had found out, that there was a natural action at a diſtance between light and other bodies, by which both the reflections and refractions, as well as inflections, of the former, were conſtantly produced. To aſcertain the force and extent of this principle of action, was what had all along engaged his thoughts, and what after all, by its extreme ſubtlety, eſcaped his moſt penetrating ſpirit. However, though he has not made ſo full a diſcovery of this principle, which directs the courſe of light, as he has in regard to the power by which the planets are kept in their courſes; yet he gave the beſt directions poſſible for ſuch as ſhould be diſpoſed to carry on the work, and furniſhed matter abundantly ſufficient to animate them to the purſuit. He has indeed hereby opened a way of paſſing from optics to an entire ſyſtem of phyſics; and, if we look upon his queries as containing the hiſtory of a great man's firſt thoughts, even in that view they muſt be always at leaſt entertaining and curious.

This ſame year, and in the ſame book with his Optics, he publiſhed, for the firſt time, his Method of Fluxions. It has been already obſerved, that theſe two inventions were intended for the public ſo long before as 1672; but were laid by then, in order to prevent his being engaged on that account in a diſpute about them. And it is not a little remarkable, that even now this laſt piece proved the occaſion of another diſpute, which continued for many years. Ever ſince 1684, Leibnitz had been artfully working the world into an opinion, that he firſt invented this method.—Newton ſaw his deſign from the beginning, and had ſufficiently obviated it in the firſt edition of the Principia, in 1687 (viz, in the Scholium to the 2d lemma of the 2d book): and with the ſame view, when he now publiſhed that method, he took occaſion to acquaint the world, that he invented it in the years 1665 and 1666. In the Acta Eruditorum of Leipſic, where an account is given of this book, the author of that account aſcribed the invention to Leibnitz, intimating that Newton borrowed it from him. Dr. Keill, the aſtronomical profeſſor at Oxford, undertook Newton's defence; and after ſeveral anſwers on both ſides, Leibnitz complaining to the Royal Society, this body appointed a committee of their members to examine the merits of the caſe. Theſe, after conſidering all the papers and letters relating to the point in controverſy, decided in favour of Newton and Keill; as is related at large in the life of this laſt mentioned gentleman; and theſe papers themſelves were publiſhed in 1712, under the title of Commercium Epiſtolicum Johannis Collins, 8vo.

In 1705, the honour of knighthood was conferred upon our author by queen Anne, in conſideration of his great merit. And in 1714 he was applied to by the Houſe of Commons, for his opinion upon a new method of diſcovering the longitude at ſea by ſignals, which had been laid before them by Ditton and Whiſton, in order to procure their encouragement; but the petition was thrown aſide upon reading Newton's paper delivered to the committee.

The following year, 1715, Leibnitz, with the view of bringing the world more eaſily into the belief that Newton had taken the method of fluxions from his Differential method, attempted to foil his mathematical ſkill by the famous problem of the trajectories, which he therefore propoſed to the Engliſh by way of challenge; but the ſolution of this, though the moſt difficult propoſition he was able to deviſe, and what might paſs for an arduous affair to any other, yet was hardly any more than an amuſement to Newton's penetrating genius: he received the problem at 4 o'clock in the afternoon, as he was returning from the Mint; and, though extremely fatigued with buſineſs, yet he finiſhed the ſolution before he went to bed.

As Leibnitz was privy-counſellor of juſtice to the elector of Hanover, ſo when that prince was raiſed to the Britiſh throne, Newton came more under the notice of the court; and it was for the immediate ſatisfaction of George the Firſt, that he was prevailed on to put the laſt hand to the diſpute about the invention of Fluxions. In this court, Caroline princeſs of Wales, afterwards queen conſort to George the Second, happened to have a curioſity for philoſophical enquiries; no ſooner therefore was ſhe informed of our author's attachment to the houſe of Hanover, than ſhe engaged his converſation, which ſoon endeared him to her. Here ſhe found in every difficulty that full ſatisfaction, which ſhe had in vain ſought for elſewhere; and ſhe was often heard to declare publicly, that ſhe thought herſelf happy in coming into the world at a juncture of time, which put it in her power to converſe with him. It was at this princeſs's ſolicitation, that he drew up an abſtract of his Chronology; a copy of which was at her requeſt communicated, about 1718, to ſignior Conti, a Venetian nobleman, then in England, upon a promiſe to keep it ſecret. But notwithſtanding this promiſe, the abbé, who while here had alſo affected to ſhew a particular friendſhip for Newton, though privately betraying him as much as lay in his power to Leibnitz, was no ſooner got acroſs the water into France, than he diſperſed copies of it, and procured an antiquary to tranſlate it into French, as well as to write a confutation of it. This, being printed at Paris in 1725, was delivered as a preſent from the bookſeller that printed it to our author, that he might obtain, as was ſaid, his conſent

to

to the publication; but though he expreſsly refuſed ſuch conſent, yet the whole was publiſhed the ſame year. Hereupon Newton found it neceſſary to publiſh a Defence of himſelf, which was inſerted in the Philoſophical Tranſactions. Thus he, who had ſo much all his life long been ſtudious to avoid diſputes, was unavoidably all his life time, in a manner, involved in them; nor did this laſt diſpute even finiſh at his death, which happened the year following. Newton's paper was republiſhed in 1726 at Paris, in French, with a letter of the abbé Conti in anſwer to it; and the ſame year ſome diſſertations were printed there by father Souciet againſt Newton's Chronological Index, an anſwer to which was inſerted by Halley in the Philoſophical Tranſactions, numb. 397.

Some time before this buſineſs, in his 80th year, our author was ſeized with an incontinence of urine, thought to proceed from the ſtone in the bladder, and deemed to be incurable. However, by the help of a ſtrict regimen and other precautions, which till then he never had occaſion for, he procured conſiderable intervals of eaſe during the five remaining years of his life. Yet he was not free from ſome ſevere paroxyſms, which even forced out large drops of ſweat that ran down his face. In theſe circumſtances he was never obſerved to utter the leaſt complaint, nor expreſs the leaſt impatience; and as ſoon as he had a moment's eaſe, he would ſmile and talk with his uſual chearfulneſs. He was now obliged to rely upon Mr. Conduit, who had married his niece, for the diſcharge of his office in the Mint. Saturday morning March 18, 1727, he read the newſpapers, and diſcourſed a long time with Dr. Mead his phyſician, having then the perfect uſe of all his ſenſes and his underſtanding; but that night he entirely loſt them all, and, not recovering them afterwards, died the Monday following, March 20, in the 85th year of his age. His corpſe lay in ſtate in the Jeruſalem-chamber, and on the 28th was conveyed into Weſtminſter-abbey, the pall being ſupported by the lord chancellor, the dukes of Montroſe and Roxburgh, and the earls of Pembroke, Suſſex, and Macclesfield. He was interred near the entrance into the choir on the left hand, where a ſtately monument is erected to his memory, with a moſt elegant inſcription upon it.

Newton's character has been attempted by M. Fontenelle and Dr. Pemberton, the ſubſtance of which is as follows. He was of a middle ſtature, and ſomewhat inclined to be fat in the latter part of his life. His countenance was pleaſing and venerable at the ſame time; eſpecially when he took off his peruke, and ſhewed his white hair, which was pretty thick. He never made uſe of ſpectacles, and loſt but one tooth during his whole life. Biſhop Atterbury ſays, that, in the whole air of Sir Iſaac's face and make, there was nothing of that penetrating ſagacity which appears in his compoſitions; that he had ſomething rather languid in his look and manner, which did not raiſe any great expectation in thoſe who did not know him.

His temper it is ſaid was ſo equal and mild, that no accident could diſturb it. A remarkable inſtance of which is related as follows. Sir Iſaac had a favourite little dog, which he called Diamond. Being one day called out of his ſtudy into the next room, Diamond was left behind. When Sir Iſaac returned, having been abſent but a few minutes, he had the mortification to find, that Diamond having overſet a lighted candle among ſome papers, the nearly finiſhed labour of many years was in flames, and almoſt conſumed to aſhes. This loſs, as Sir Iſaac was then very far advanced in years, was irretrievable; yet, without once ſtriking the dog, he only rebuked him with this exclamation, "Oh Diamond! Diamond! thou little knoweſt the miſchief thou haſt done!"

He was indeed of ſo meek and gentle a diſpoſition, and ſo great a lover of peace, that he would rather have choſen to remain in obſcurity, than to have the calm of life ruffled by thoſe ſtorms and diſputes, which genius and learning always draw upon thoſe that are the moſt eminent for them.

From his love of peace, no doubt, aroſe that unuſual kind of horror which he felt for all diſputes: a ſteady unbroken attention, free from thoſe frequent recoilings inſeparably incident to others, was his peculiar felicity; he knew it, and he knew the value of it. No wonder then that controverſy was looked on as his bane. When ſome objections, haſtily made to his diſcoveries concerning light and colours, induced him to lay aſide the deſign he had taken of publiſhing his Optical Lectures, we find him reflecting on that diſpute, into which he had been unavoidably drawn, in theſe terms: "I blamed my own imprudence for parting with ſo real a bleſſing as my quiet, to run after a ſhadow." It is true this ſhadow, as Fontenelle obſerves, did not eſcape him afterwards, nor did it coſt him that quiet which he ſo much valued, but proved as much a real happineſs to him as his quiet itſelf; yet this was a happineſs of his own making: he took a reſolution from theſe diſputes, not to publiſh any more concerning that theory, till he had put it above the reach of controverſy, by the exacteſt experiments, and the ſtricteſt demonſtrations; and accordingly it has never been called in queſtion ſince. In the ſame temper, after he had ſent the manuſcript to the Royal Society, with his conſent to the printing of it by them; yet upon Hook's injuriouſly inſiſting that he himſelf had demonſtrated Kepler's problem before our author, he determined, rather than be involved again in a controverſy, to ſuppreſs the third book; and he was very hardly prevailed upon to alter that reſolution. It is true, the public was thereby a gainer; that book, which is indeed no more than a corollary of ſome propoſitions in the firſt, being originally drawn up in the popular way, with a deſign to publiſh it in that form; whereas he was now convinced that it would be beſt not to let it go abroad without a ſtrict demonſtration.

In contemplating his genius, it preſently becomes a doubt, which of theſe endowments had the greateſt ſhare, ſagacity, penetration, ſtrength, or diligence; and, after all, the mark that ſeems moſt to diſtinguiſh it is, that he himſelf made the juſteſt eſtimation of it, declaring, that if he had done the world any ſervice, it was due to nothing but induſtry and patient thought; that he kept the ſubject of conſideration conſtantly before him, and waited till the firſt dawning opened gradually, by little and little, into a full and clear light. It is ſaid, that when he had any mathematical problems or ſolutions in his mind, he would never quit the ſubject on any account. And his ſervant has

ſaid,

ſaid, when he has been getting up in a morning, he has ſometimes begun to dreſs, and with one leg in his breeches, ſat down again on the bed, where he has remained for hours before he has got his clothes on: and that dinner has been often three hours ready for him before he could be brought to table. Upon this head ſeveral little anecdotes are related; among which is the following: Doctor Stukely coming in accidentally one day, when Newton's dinner was left for him upon the table, covered up, as uſual, to keep it warm till he ſhould find it convenient to come to table; the doctor lifting the cover, found under it a chicken, which he preſently ate, putting the bones in the diſh, and replacing the cover. Some time after Newton came into the room, and after the uſual compliments ſat down to his dinner; but on taking up the cover, and ſeeing only the bones of the fowl left, he obſerved with ſome little ſurpriſe, "I thought I had not dined, but I now find that I have."

After all, notwithſtanding his anxious care to avoid every occaſion of breaking his intenſe application to ſtudy, he was at a great diſtance from being ſteeped in philoſophy. On the contrary, he could lay aſide his thoughts, though engaged in the moſt intricate reſearches, when his other affairs required his attention; and, as ſoon as he had leiſure, reſume the ſubject at the point where he had left off. This he ſeems to have done not ſo much by any extraordinary ſtrength of memory, as by the force of his inventive faculty, to which every thing opened itſelf again with eaſe, if nothing intervened to ruffle him. The readineſs of his invention made him not think of putting his memory much to the trial; but this was the offspring of a vigorous intenſeneſs of thought, out of which he was but a common man. He ſpent therefore the prime of his age in thoſe abſtruſe reſearches, when his ſituation in a college gave him leiſure, and while ſtudy was his proper buſineſs. But as ſoon as he was removed to the mint, he applied himſelf chiefly to the duties of that office; and ſo far quitted mathematics and philoſophy, as not to engage in any purſuits of either kind afterwards.

Dr. Pemberton obſerves, that though his memory was much decayed in the laſt years of his life, yet he perfectly underſtood his own writings, contrary to what I had formerly heard, ſays the doctor, in diſcourſe from many perſons. This opinion of theirs might ariſe perhaps from his not being always ready at ſpeaking on theſe ſubjects, when it might be expected he ſhould. But on this head it may be obſerved, that great geniuſes are often liable to be abſent, not only in relation to common life, but with regard to ſome of the parts of ſcience that they are beſt informed of: inventors ſeem to treaſure up in their minds what they have found out, after another manner, than thoſe do the ſame things, who have not this inventive faculty. The former, when they have occaſion to produce their knowledge, are in ſome meaſure obliged immediately to inveſtigate part of what they want; and for this they are not equally fit at all times: from whence it has often happened, that ſuch as retain things chiefly by means of a very ſtrong memory, have appeared off-hand more expert than the diſcoverers themſelves.

It was evidently owing to the ſame inventive faculty that Newton, as this writer found, had read fewer of the modern mathematicians than one could have expected; his own prodigious invention readily ſupplying him with what he might have occaſion for in the purſuit of any ſubject he undertook. However, he often cenſured the handling of geometrical ſubjects by algebraic calculations; and his book of algebra he called by the name of *Univerſal Arithmetic*, in oppoſition to the injudicious title of *Geometry* which Des Cartes had given to the treatiſe in which he ſhews how the geometrician may aſſiſt his invention by ſuch kind of computations. He frequently praiſed Slulius, Barrow, and Huygens, for not being influenced by the falſe taſte which then began to prevail. He uſed to commend the laudable attempt of Hugo d'Omerique to reſtore the ancient analyſis; and very much eſteemed Apollonius's book *De Sectione Rationis*, for giving us a clearer notion of that analyſis than we had before. Dr. Barrow may be eſteemed as having ſhewn a compaſs of invention equal, if not ſuperior, to any of the Moderns, our author only excepted; but Newton particularly recommended Huygens's ſtyle and manner: he thought him the moſt elegant of any mathematical writer of modern times, and the trueſt imitator of the Ancients. Of their taſte and mode of demonſtration our author always profeſſed himſelf a great admirer; and even cenſured himſelf for not following them yet more cloſely than he did; and ſpoke with regret of his miſtake at the beginning of his mathematical ſtudies, in applying himſelf to the works of Des Cartes, and other algebraic writers, before he had conſidered the Elements of Euclid with that attention which ſo excellent a writer deſerves.

But if this was a fault, it is certain it was a fault to which we owe both his great inventions in ſpeculative mathematics, and the doctrine of Fluxions and Infinite Series. And perhaps this might be one reaſon why his particular reverence for the Ancients is omitted by Fontenelle, who however certainly makes ſome amends by that juſt elogium which he makes of our author's modeſty, which amiable quality he repreſents as ſtanding foremoſt in the character of this great man's mind and manners. It was in reality greater than can be eaſily imagined, or will be readily believed: yet it always continued ſo without any alteration; though the whole world, ſays Fontenelle, conſpired againſt it; let us add, though he was thereby robbed of his invention of Fluxions. Nicholas Mercator publiſhing his *Logarithmotechnia* in 1668, where he gave the quadrature of the hyperbola by an infinite ſeries, which was the firſt appearance in the learned world of a ſeries of this ſort drawn from the particular nature of the curve, and that in a manner very new and abſtracted; Dr. Barrow, then at Cambridge, where Mr. Newton, then about 26 years of age, reſided, recollected, that he had met with the ſame thing in the writings of that young gentleman; and there not confined to the hyperbola only, but extended, by general forms, to all ſorts of curves, even ſuch as are mechanical; to their quadratures, their rectifications, and their centres of gravity; to the ſolids formed by their rotations, and to the ſuperficies of thoſe ſolids; ſo that, when their determinations were poſſible, the ſeries ſtopped at a certain point, or at leaſt their ſums were given by ſtated rules: and if the abſolute determinations were impoſſible, they could yet be infinitely approximated; which is the happieſt and moſt

refined method, fays Fontenelle, of fupplying the defects of human knowledge that man's imagination could poffibly invent. To be maſter of ſo fruitful and general a theory was a mine of gold to a geometrician; but it was a greater glory to have been the diſcoverer of ſo ſurpriſing and ingenious a ſyſtem. So that Newton, finding by Mercator's book, that he was in the way to it, and that others might follow in his track, ſhould naturally have been forward to open his treaſures, and ſecure the property, which conſiſted in making the diſcovery; but he contented himſelf with his treaſure which he had found, without regarding the glory. What an idea does it give us of his unparalleled modeſty, when we find him declaring, that he thought Mercator had entirely diſcovered his ſecret, or that others would, before he ſhould become of a proper age for writing! His manuſcript upon Infinite Series was communicated to none but Mr. John Collins and the lord Brounker, then Preſident of the Royal Society, who had alſo done ſomething in this way himſelf; and even that had not been complied with, but for Dr. Barrow, who would not ſuffer him to indulge his modeſty ſo much as he deſired.

It is further obſerved, concerning this part of his character, that he never talked either of himſelf or others, nor ever behaved in ſuch a manner, as to give the moſt malicious cenſurers the leaſt occaſion even to ſuſpect him of vanity. He was candid and affable, and always put himſelf upon a level with his company. He never thought either his merit or his reputation ſufficient to excuſe him from any of the common offices of ſocial life. No ſingularities, either natural or affected, diſtinguiſhed him from other men. Though he was firmly attached to the church of England, he was averſe to the perſecution of the non-conformiſts. He judged of men by their manners; and the true ſchiſmatics, in his opinion, were the vicious and the wicked. Not that he confined his principles to natural religion, for it is ſaid he was thoroughly perſuaded of the truth of Revelation; and amidſt the great variety of books which he had conſtantly before him, that which he ſtudied with the greateſt application was the Bible, at leaſt in the latter years of his life: and he underſtood the nature and force of moral certainty as well as he did that of a ſtrict demonſtration.

Sir Iſaac did not neglect the opportunities of doing good, when the revenues of his patrimony and a profitable employment, improved by a prudent œconomy, put it in his power. We have two remarkable inſtances of his bounty and generoſity; one to Mr. Maclaurin, extra profeſſor of mathematics at Edinburgh, to encourage whoſe appointment he offered 20 pounds a year to that office; and the other to his niece Barton, upon whom he had ſettled an annuity of 100 pounds per annum. When decency upon any occaſion required expence and ſhew, he was magnificent without grudging it, and with a very good grace: at all other times, that pomp which ſeems great to low minds only, was utterly retrenched, and the expence reſerved for better uſes.

Newton never married; and it has been ſaid, that "perhaps he never had leiſure to think of it; that, being immerſed in profound ſtudies during the prime of his age, and afterwards engaged in an employment of great importance, and even quite taken up with the company which his merit drew to him, he was not ſenſible of any vacancy in life, nor of the want of a companion at home." Theſe however do not appear to be any ſufficient reaſons for his never marrying, if he had had an inclination ſo to do. It is much more likely that he had a conſtitutional indifference to the ſtate, and even to the ſex in general; and it has even been ſaid of him, that he never once knew woman.—He left at his death, it ſeems, 32 thouſand pounds; but he made no will; which, Fontenelle tells us, was becauſe he thought a legacy was no gift.—As to his works, beſides what were publiſhed in his life-time, there were found after his death, among his papers, ſeveral diſcourſes upon the ſubjects of Antiquity, Hiſtory, Divinity, Chemiſtry, and Mathematics; ſeveral of which were publiſhed at different times, as appears from the following catalogue of all his works; where they are ranked in the order of time in which thoſe upon the ſame ſubject were publiſhed.

1. Several Papers relating to his *Teleſcope*, and his *Theory of Light and Colours*, printed in the Philoſophical Tranſactions, numbs. 80, 81, 82, 83, 84, 85, 88, 96, 97, 110, 121, 123, 128; or vols 6, 7, 8, 9, 10, 11.

2. *Optics*, or a *Treatiſe of the Reflections, Refractions, and Inflections, and the Colours of Light*; 1704, 4to.—A Latin tranſlation by Dr. Clarke; 1706, 4to.—And a French tranſlation by Pet. Coſte, Amſt. 1729, 2 vols 12mo.—Beſide ſeveral Engliſh editions in 8vo.

3. *Optical Lectures*; 1728, 8vo. Alſo in ſeveral Letters to Mr. Oldenburg, ſecretary of the Royal Society, inſerted in the General Dictionary, under our author's article.

4. *Lectiones Opticæ*; 1729, 4to.

5. *Naturalis Philoſophiæ Principia Mathematica*; 1687, 4to.—A ſecond edition in 1713, with a Preface, by Roger Cotes.—The 3d edition in 1726, under the direction of Dr. Pemberton.—An Engliſh tranſlation, by Motte, 1729, 2 volumes 8vo, printed in ſeveral editions of his works, in different nations, particularly an edition, with a large Commentary, by the two learned Jeſuits, Le Seur and Jacquier, in 4 volumes 4to, in 1739, 1740, and 1742.

6. *A Syſtem of the World*, tranſlated from the Latin original; 1727, 8vo.—This, as has been already obſerved, was at firſt intended to make the third book of his Principia.—An Engliſh tranſlation by Motte, 1729, 8vo.

7. *Several Letters* to Mr. Flamſteed, Dr. Halley, and Mr. Oldenburg.—See our author's article in the General Dictionary.

8. *A Paper concerning the Longitude*; drawn up by order of the Houſe of Commons; ibid.

9. *Abregé de Chronologie*, &c; 1726, under the direction of the abbé Conti, together with ſome Obſervations upon it.

10. *Remarks upon the Obſervations made upon a Chronological Index of Sir I. Newton*, &c. Philoſ. Tranſ. vol. 33, See alſo the ſame, vol. 34 and 35, by Dr. Halley.

11. The Chronology of Ancient Kingdoms amended, &c; 1728, 4to.

12. *Arithmetica Univerſalis*, &c; under the inſpec-

tion of Mr. Whiſton, Cantab. 1707, 8vo. Printed I think without the author's conſent, and even againſt his will: an offence which it ſeems was never forgiven. There are alſo Engliſh editions of the ſame, particularly one by Wilder, with a Commentary, in 1769, 2 vols 8vo. And a Latin edition, with a Commentary, by Caſtilion, 2 vols 4to, Amſt. &c.

13. *Analyſis per Quantitatum Series, Fluxiones, et Differentias, cum Enumeratione Linearum Tertii Ordinis*; 1711, 4to; under the inſpection of W. Jones, Eſq. F. R. S.—The laſt tract had been publiſhed before, together with another on the *Quadrature of Curves*, by the Method of Fluxions, under the title of *Tractatus duo de Speciebus & Magnitudine Figurarum Curvilinearum*; ſubjoined to the firſt edition of his Optics in 1704; and other letters in the Appendix to Dr. Gregory's Catoptrics, &c, 1735, 8vo.—Under this head may be ranked *Newtoni Geneſis Curvarum per Umbras*; Leyden, 1740.

14. *Several Letters relating to his Diſpute with Leibnitz*, upon his Right to the Invention of Fluxions; printed in the *Commercium Epiſtolicum D. Johannis Collins & aliorum de Analyſi Promota, juſſu Societatis Regiæ editum*; 1712, 8vo.

15. Poſtſcript and Letter of M. Leibnitz to the Abbé Conti, with Remarks, and a Letter of his own to that Abbé; 1717, 8vo. To which was added, Raphſon's Hiſtory of Fluxions, as a Supplement.

16. *The Method of Fluxions, and Analyſis by Infinite Series*, tranſlated into Engliſh from the original Latin; to which is added, a Perpetual Commentary, by the tranſlator Mr. John Colſon; 1736, 4to.

17. *Several Miſcellaneous Pieces, and Letters*, as follow:—(1). A Letter to Mr. Boyle upon the ſubject of the Philoſopher's Stone. Inſerted in the General Dictionary, under the article BOYLE.—(2). A Letter to Mr. Aſton, containing directions for his travels; ibid. under our author's article.—(3). An Engliſh Tranſlation of a Latin Diſſertation upon the Sacred Cubit of the Jews. Inſerted among the miſcellaneous works of Mr. John Greaves, vol. 2, publiſhed by Dr. Thomas Birch, in 1737, 2 vols 8vo. This Diſſertation was found ſubjoined to a work of Sir Iſaac's, not finiſhed, intitled *Lexicon Propheticum*.—(4). Four Letters from Sir Iſaac Newton to Dr. Bentley, containing ſome arguments in proof of a Deity; 1756, 8vo.—(5). Two Letters to Mr. Clarke, &c.

18. *Obſervations on the Prophecies of Daniel and the Apocalypſe of St. John*; 1733, 4to.

19. *Is. Newtoni Elementa Perſpectivæ Univerſalis*; 1746, 8vo.

20. *Tables for purchaſing College Leaſes*; 1742, 12mo.

21. Corollaries, by Whiſton.

22. A Collection of ſeveral pieces of our author's, under the following title, *Newtoni Is. Opuſcula Mathematica Philoſ. & Philol.* collegit J. Caſtilioneus; Lauſ. 1744, 4to, 3 tomes.

23. *Two Treatiſes* of the Quadrature of Curves, and Analyſis by Equations of an Infinite Number of Terms, explained: tranſlated by John Stewart, with a large Commentary; 1745, 4to.

24. *Deſcription of an Inſtrument* for obſerving the Moon's Diſtance from the Fixed Stars at Sea. Philoſ. Tranſ. vol. 42.

25. Newton alſo publiſhed *Barrow's Optical Lectures*, in 1699, 4to: and *Bern. Varenii Geographia, &c*; 1681, 8vo.

26. The whole works of Newton, publiſhed by Dr. Horſley; 1779, 4to, in 5 volumes.

The following is a liſt of the papers left by Newton at his death, as mentioned above.

A Catalogue of Sir Iſaac Newton's Manuſcripts and Papers, as annexed to a Bond, given by Mr. Conduit, to the Adminiſtrators of Sir Iſaac; by which he obliges himſelf to account for any profit he ſhall make by publiſhing any of the papers.

Dr. Pellet, by agreement of the executors, entered into Acts of the Prerogative Court, being appointed to peruſe all the papers, and judge which were proper for the preſs.

No.

1. Viaticum Nautarum; by Robert Wright.
2. Miſcellanea; not in Sir Iſaac's hand writing.
3. Miſcellanea; part in Sir Iſaac's hand.
4. Trigonometria; about 5 ſheets.
5. Definitions.
6. Miſcellanea; part in Sir Iſaac's hand.
7. 40 ſheets in 4to, relating to Church Hiſtory.
8. 126 ſheets written on one ſide, being foul draughts of the Prophetic Stile.
9. 88 ſheets relating to Church Hiſtory.
10. About 70 looſe ſheets in ſmall 4to, of Chemical papers; ſome of which are not in Sir Iſaac's hand.
11. About 62 ditto, in folio.
12. About 15 large ſheets, doubled into 4to; Chemical.
13. About 8 ſheets ditto, written on one ſide.
14. About 5 ſheets of foul papers, relating to Chemiſtry.
15. 12 half-ſheets of ditto.
16. 104 half-ſheets, in 4to, ditto.
17. About 22 ſheets in 4to, ditto.
18. 24 ſheets, in 4to, upon the Prophecies.
19. 29 half-ſheets; being an anſwer to Mr. Hook, on Sir Iſaac's Theory of Colours.
20. 87 half-ſheets relating to the Optics, ſome of which are not in Sir Iſaac's hand.

From No. 1 to No. 20 examined on the 20th of May 1727, and judged not fit to be printed.

T. Pellet.

Witneſs, *Tho. Pilkington.*

21. 328 half-ſheets in folio, and 63 in ſmall 4to; being looſe and foul papers relating to the Revelations and Prophecies.
22. 8 half-ſheets in ſmall 4to, relating to Church Matters.
23. 24 half-ſheets in ſmall 4to; being a diſcourſe relating to the 2d of Kings.
24. 353 half-ſheets in folio, and 57 in ſmall 4to; being foul and looſe papers relating to Figures and Mathematics.
25. 201 half-ſheets in folio, and 21 in ſmall 4to; looſe and foul papers relating to the Commercium Epiſtolicum.

26. 91 half-ſheets in ſmall 4to, in Latin, upon the Temple of Solomon.
27. 37 half-ſheets in folio, upon the Hoſt of Heaven, the Sanctuary, and other Church Matters.
28. 44 half-ſheets in folio, upon Ditto.
29. 25 half-ſheets in folio; being a farther account of the Hoſt of Heaven.
30. 51 half-ſheets in folio; being an Hiſtorical Account of two notable Corruptions of Scripture.
31. 88 half-ſheets in ſmall 4to; being Extracts of Church Hiſtory.
32. 116 half-ſheets in folio; being Paradoxical Queſtions concerning Athanaſius, of which ſeveral leaves in the beginning are very much damaged.
33. 56 half-ſheets in folio, De Motu Corporum; the greateſt part not in Sir Iſaac's hand.
34. 61 half-ſheets in ſmall 4to; being various ſections on the Apocalypſe.
35. 25 half-ſheets in folio, of the Working of the Myſtery of Iniquity.
36. 20 half-ſheets in folio, of the Theology of the Heathens.
37. 24 half-ſheets in folio; being an Account of the Conteſt between the Hoſt of Heaven, and the Tranſgreſſors of the Covenant.
38. 31 half-ſheets in folio; being Paradoxical Queſtions concerning Athanaſius.
39. 107 quarter-ſheets in ſmall 4to, upon the Revelations.
40. 174 half-ſheets in folio; being looſe papers relating to Church Hiſtory.

May 22, 1727, examined from No. 21 to No. 40 incluſive, and judged them not fit to be printed; only No. 33 and No. 38 ſhould be reconſidered.

T. Pellet.

Witneſs, *Tho. Pilkington.*

41. 167 half-ſheets in folio; being looſe and foul papers relating to the Commercium Epiſtolicum.
42. 21 half-ſheets in folio; being the 3d letter upon Texts of Scripture, very much damaged.
43. 31 half-ſheets in folio; being foul papers relating to Church Matters.
44. 495 half-ſheets in folio; being looſe and foul papers relating to Calculations and Mathematics.
45. 335 half-ſheets in folio; being looſe and foul papers relating to the Chronology.
46. 112 ſheets in ſmall 4to, relating to the Revelations and other Church Matters.
47. 126 half-ſheets in folio; being looſe papers relating to the Chronology, part in Engliſh and part in Latin.
48. 400 half-ſheets in folio; being looſe Mathematical papers.
49. 109 ſheets in 4to, relating to the Prophecies, and Church Matters.
50. 127 half-ſheets in folio, relating to the Univerſity; great part not in Sir Iſaac's hand.
51. 18 ſheets in 4to; being Chemical papers.
52. 255 quarter-ſheets; being Chemical papers.
53. An Account of Corruptions of Scripture; not in Sir Iſaac's hand.
54. 31 quarter-ſheets; being Flammell's Explication of Hieroglyphical Figures.
55. About 350 half-ſheets; being Miſcellaneous papers.
56. 6 half-ſheets; being An Account of the Empires &c repreſented by St. John.
57. 9 half-ſheets folio, and 71 quarter-ſheets 4to; being Mathematical papers.
58. 140 half-ſheets, in 9 chapters, and 2 pieces in folio, titled, Concerning the Language of the Prophets.
59. 606 half-ſheets folio, relating to the Chronology; 9 more in Latin.
60. 182 half-ſheets folio; being looſe papers relating to the Chronology and Prophecies.
61. 144 quarter-ſheets, and 95 half-ſheets folio; being looſe Mathematical papers.
62. 137 half-ſheets folio; being looſe papers relating to the Diſpute with Leibnitz.
63. A folio Common-place book; part in Sir Iſaac's hand.
64. A bundle of Engliſh Letters to Sir Iſaac, relating to Mathematics.
65. 54 half-ſheets; being looſe papers found in the Principia.
66. A bundle of looſe Mathematical Papers; not Sir Iſaac's.
67. A bundle of French and Latin Letters to Sir Iſaac.
68. 136 ſheets folio, relating to Optics.
69. 22 half-ſheets folio, De Rationibus Motuum &c; not in Sir Iſaac's hand.
70. 70 half-ſheets folio; being looſe Mathematical Papers.
71. 38 half-ſheets folio; being looſe papers relating to Optics.
72. 47 half-ſheets folio; being looſe papers relating to Chronology and Prophecies.
73. 40 half-ſheets folio; Proceſtus Myſterii Magni Philoſophicus, by Wm. Yworth; not in Sir Iſaac's hand.
74. 5 half-ſheets; being a letter from Rizzetto to Martine, in Sir Iſaac's hand.
75. 41 half-ſheets; being looſe papers of ſeveral kinds, part in Sir Iſaac's hand.
76. 40 half-ſheets; being looſe papers, foul and dirty, relating to Calculations.
77. 90 half-ſheets folio; being looſe Mathematical papers.
78. 176 half-ſheets folio; being looſe papers relating to Chronology.
79. 176 half-ſheets folio; being looſe papers relating to the Prophecies.
80. { 12 half-ſheets folio; An Abſtract of the Chronology. 92 half-ſheets, folio; The Chronology.
81. 40 half-ſheets folio; The Hiſtory of the Prophecies, in 10 chapters, and part of the 11th unfiniſhed.
82. 5 ſmall bound books in 12mo, the greateſt part not in Sir Iſaac's hand, being rough Calculations.

May

May 26th 1727, Examined from No. 41 to No. 82 inclusive, and judged not fit to be printed, except No. 80, which is agreed to be printed, and part of No. 61 and 81, which are to be reconsidered.

Th. Pellet.
Witness, *Tho. Pilkington.*

It is astonishing what care and industry Sir Isaac had employed about the papers relating to Chronology, Church History, &c; as, on examining the papers themselves, which are in the possession of the family of the earl of Portsmouth, it appears that many of them are copies over and over again, often with little or no variation; the whole number being upwards of 4000 sheets in folio, or 8 reams of folio paper; beside the bound books &c in this catalogue, of which the number of sheets is not mentioned. Of these there have been published only the Chronology, and Observations on the Prophecies of Daniel and the Apocalypse of St. John.

NEWTONIAN *Philosophy*, the doctrine of the universe, or the properties, laws, affections, actions, forces, motions, &c of bodies, both celestial and terrestrial, as delivered by Newton.

This term however is differently applied; which has given occasion to some confused notions relating to it. For, some authors, under this term, include all the corpuscular philosophy, considered as it now stands reformed and corrected by the discoveries and improvements made in several parts of it by Newton. In which sense it is, that Gravesande calls his Elements of Physics, Introductio ad Philosophiam Newtonianam. And in this sense the Newtonian is the same as the new philosophy; and stands contradistinguished from the Cartesian, the Peripatetic, and the ancient Corpuscular.

Others, by Newtonian Philosophy, mean the method or order used by Newton in philosophising; viz, the reasoning and inferences drawn directly from phenomena, exclusive of all previous hypotheses; the beginning from simple principles, and deducing the first powers and laws of nature from a few select phenomena, and then applying those laws &c to account for other things. In this sense, the Newtonian Philosophy is the same with the Experimental Philosophy, or stands opposed to the ancient Corpuscular, and to all hypothetical and fanciful systems of Philosophy.

Others again, by this term, mean that Philosophy in which physical bodies are considered mathematically, and where geometry and mechanics are applied to the solution of phenomena. In which sense, the Newtonian is the same with the Mechanical and Mathematical Philosophy.

Others, by Newtonian Philosophy, understand that part of physical knowledge which Newton has handled, improved, and demonstrated.

And lastly, others, by this Philosophy, mean the new principles which Newton has brought into Philosophy; with the new system founded upon them, and the new solutions of phenomena thence deduced; or that which characterizes and distinguishes his Philosophy from all others. And this is the sense in which we shall here chiefly consider it.

As to the history of this Philosophy, consult the foregoing article. It was first published in the year 1687, the author being then professor of mathematics in the university of Cambridge; a 2d edition, with considerable additions and improvements, came out in 1713; and a 3d in 1726. An edition, with a very large Commentary, came out in 1739, by Le Seur and Jacquier; besides the complete edition of all Newton's works, with notes, by Dr. Horsley, in 1779 &c. Several authors have endeavoured to make it plainer; by setting aside many of the more sublime mathematical researches, and substituting either more obvious reasonings or experiments instead of them; particularly Whiston, in his Prælect. Phys. Mathem.; Gravesande, in Elem. & Inst.; Pemberton, in his View &c; and Maclaurin, in his Account of Newton's Philosophy.

The chief parts of the Newtonian Philosophy, as delivered by the author, except his Optical Discoveries &c, are contained in his Principia, or Mathematical Principles of Natural Philosophy. He founds his system on the following definitions.

1. Quantity of Matter, is the measure of the same, arising from its density and bulk conjointly.—Thus, air of a double density, in the same space, is double in quantity; in a double space, is quadruple in quantity; in a triple space, is sextuple in quantity, &c.

2. Quantity of Motion, is the measure of the same, arising from the velocity and quantity of matter conjunctly.—This is evident, because the motion of the whole is the motion of all its parts; and therefore in a body double in quantity, with equal velocity, the Motion is double, &c.

3. The Vis Insita, Vis Inertiæ, or innate force of matter, is a power of resisting, by which every body, as much as in it lies, endeavours to persevere in its present state, whether it be of rest, or moving uniformly forward in a right line.—This definition is proved to be just by experience, from observing the difficulty with which any body is moved out of its place, upwards, or obliquely, or even downwards when acted on by a body endeavouring to urge it quicker than the velocity given it by gravity; and any how to change its state of motion or rest. And therefore this force is the same, whether the body have gravity or not; and a cannon ball, void of gravity, if it could be, being discharged horizontally, will go the same distance in that direction, in the same time, as if it were endued with gravity.

4. An Impressed Force, is an action exerted upon a body, in order to change its state, whether of rest or motion.—This force consists in the action only; and remains no longer in the body when the action is over. For a body maintains every new state it acquires, by its vis inertiæ only.

5. A Centripetal Force, is that by which bodies are drawn, impelled, or any way tend towards a point, as to a centre.—This may be considered of three kinds, absolute, accelerative, and motive.

6. The Absolute quantity of a centripetal force, is a measure of the same, proportional to the efficacy of the cause that urges it to the centre.

7. The Accelerative quantity of a centripetal force, is the measure of the same, proportional to the velocity which it generates in a given time.

8. The

8. The Motive quantity of a centripetal force, is a meaſure of the ſame, proportional to the motion which it generates in a given time.—This is always known by the quantity of a force equal and contrary to it, that is juſt ſufficient to hinder the deſcent of the body.

After theſe definitions, follow certain Scholia, treating of the nature and diſtinctions of Time, Space, Place, Motion, Abſolute, Relative, Apparent, True, Real, &c. After which, the author propoſes to ſhew how we are to collect the true motions from their cauſes, effects, and apparent differences; and vice verſa, how, from the motions, either true or apparent, we may come to the knowledge of their cauſes and effects. In order to this, he lays down the following axioms or laws of motion.

1ſt Law. Every body perſeveres in its ſtate of reſt, or of uniform motion in a right line, unleſs it be compelled to change that ſtate by forces impreſſed upon it. —Thus, "Projectiles perſevere in their motions, ſo far as they are not retarded by the reſiſtance of the air, or impelled downwards by the force of gravity. A top, whoſe parts, by their coheſion, are perpetually drawn aſide from rectilinear motions, does not ceaſe its rotation otherwiſe than as it is retarded by the air. The greater bodies of the planets and comets, meeting with leſs reſiſtance in more free ſpaces, preſerve their motions, both progreſſive and circular, for a much longer time."

2d Law. The Alteration of motion is always proportional to the motive force impreſſed; and is made in the direction of the right line in which that force is impreſſed. Thus, if any force generate a certain quantity of motion, a double force will generate a double quantity, whether that force be impreſſed all at once, or in ſucceſſive moments.

3d Law. To every action there is always oppoſed an equal re-action: or the mutual actions of two bodies upon each other, are always equal, and directed to contrary parts. Thus, whatever draws or preſſes another, is as much drawn or preſſed by that other. If you preſs a ſtone with your finger, the finger is alſo preſſed by the ſtone: &c.

From this axiom, or law, Newton deduces the following corollaries.

1. A body by two forces conjoined will deſcribe the diagonal of a parallelogram, in the ſame time that it would deſcribe the ſides by thoſe forces apart.

2. Hence is explained the compoſition of any one direct force out of any two oblique ones, viz, by making the two oblique forces the ſides of a parallelogram, and the diagonal the direct one.

3. The quantity of motion, which is collected by taking the ſum of the motions directed towards the ſame parts, and the difference of thoſe that are directed to contrary parts, ſuffers no change from the action of bodies among themſelves; becauſe the motion which one body loſes, is communicated to another.

4. The common centre of gravity of two or more bodies does not alter its ſtate of motion or reſt by the actions of the bodies among themſelves; and therefore the common centre of gravity of all bodies, acting upon each other, (excluding external actions and impediments) is either at reſt, or moves uniformly in a right line.

5. The motions of bodies included in a given ſpace are the ſame among themſelves, whether that ſpace be at reſt, or move uniformly forward in a right line without any circular motion. The truth of this is evident from the experiment of a ſhip; where all motions are juſt the ſame, whether the ſhip be at reſt, or proceed uniformly forward in a ſtraight line.

6. If bodies, any how moved among themſelves, be urged in the direction of parallel lines by equal accelerative forces, they will all continue to move among themſelves, after the ſame manner as if they had not been urged by ſuch forces.

The mathematical part of the Newtonian Philoſophy depends chiefly on the following lemmas; eſpecially the firſt; containing the doctrine of prime and ultimate ratios.

Lem. 1. Quantities, and the ratios of quantities, which in any finite time converge continually to equality, and before the end of that time approach nearer the one to the other than by any given difference, become ultimately equal.

Lem. 2 ſhews, that in a ſpace bounded by two right lines and a curve, if an infinite number of parallelograms be inſcribed, all of equal breadth; then the ultimate ratio of the curve ſpace and the ſum of the parallelograms, will be a ratio of equality.

Lem. 3 ſhews, that the ſame thing is true when the breadths of the parallelograms are unequal.

In the ſucceeding lemmas it is ſhewn, in like manner, that the ultimate ratios of the ſine, chord, and tangent of arcs infinitely diminiſhed, are ratios of equality, and therefore that in all our reaſonings about theſe, we may ſafely uſe the one for the other:—that the ultimate form of evaneſcent triangles, made by the arc, chord, or tangent, is that of ſimilitude, and their ultimate ratio is that of equality; and hence, in reaſonings about ultimate ratios, theſe triangles may ſafely be uſed one for another, whether they are made with the ſine, the arc, or the tangent.—He then demonſtrates ſome properties of the ordinates of curvilinear figures; and ſhews that the ſpaces which a body deſcribes by any finite force urging it, whether that force is determined and immutable, or continually varied, are to each other, in the very beginning of the motion, in the duplicate ratio of the forces:—and laſtly, having added ſome demonſtrations concerning the evaneſcence of angles of contact, he proceeds to lay down the mathematical part of his ſyſtem, which depends on the following theorems.

Theor. 1. The areas which revolving bodies deſcribe by radii drawn to an immoveable centre of force, lie in the ſame immoveable planes, and are proportional to the times in which they are deſcribed.—To this prop. are annexed ſeveral corollaries, reſpecting the velocities of bodies revolving by centripetal forces, the directions and proportions of thoſe forces, &c; ſuch as, that the velocity of ſuch a revolving body, is reciprocally as the perpendicular let fall from the centre of force upon the line touching the orbit in the place of the body, &c.

Theor. 2. Every body that moves in any curve line

ſine deſcribed in a plane, and, by a radius drawn to a point either immoveable or moving forward with an uniform rectilinear motion, deſcribes about that point areas proportional to the times, is urged by a centripetal force directed to that point.—With corollaries relating to ſuch motions in reſiſting mediums, and to the direction of the forces when the areas are not proportional to the times.

THEOR. 3. Every body that, by a radius drawn to the centre of another body, any how moved, deſcribes areas about that centre proportional to the times, is urged by a force compounded of the centripetal forces tending to that other body, and of the whole accelerative force by which that other body is impelled.—With ſeveral corollaries.

THEOR. 4. The centripetal forces of bodies, which by equal motions deſcribe different circles, tend to the centres of the ſame circles; and are one to the other as the ſquares of the arcs deſcribed in equal times, applied to the radii of the circles.—With many corollaries, relating to the velocities, times, periodic forces, &c. And, in ſcholium, the author farther adds, Moreover, by means of the foregoing propoſition and its corollaries, we may diſcover the proportion of a centripetal force to any other known force, ſuch as that of gravity. For if a body by means of its gravity revolve in a circle, concentric to the earth, this gravity is the centripetal force of that body. But from the deſcent of heavy bodies, the time of one entire revolution, as well as the arc deſcribed in any given time, is given by a corol. to this prop. And by ſuch propoſitions, Mr. Huygens, in his excellent book De Horologio Oſcillatorio, has compared the force of gravity with the centrifugal forces of revolving bodies.

On theſe, and ſuch-like principles, depends the Newtonian Mathematical Philoſophy. The author farther ſhews how to find the centre to which the forces impelling any body are directed, having the velocity of the body given: and finds that the centrifugal force is always as the verſed ſine of the naſcent arc directly, and as the ſquare of the time inverſely; or directly as the ſquare of the velocity, and inverſely as the chord of the naſcent arc. From theſe premiſes, he deduces the method of finding the centripetal force directed to any given point when the body revolves in a circle; and this whether the central point be near hand, or at immenſe diſtance; ſo that all the lines drawn from it may be taken for parallels. And he ſhews the ſame thing with regard to bodies revolving in ſpirals, ellipſes, hyperbolas, or parabolas. He ſhews alſo, having the figures of the orbits given, how to find the velocities and moving powers; and indeed reſolves all the moſt difficult problems relating to the celeſtial bodies with a ſurpriſing degree of mathematical ſkill. Theſe problems and demonſtrations are all contained in the firſt book of the Principia: but an account of them here would neither be generally underſtood, nor eaſily comprized in the limits of this work.

In the ſecond book, Newton treats of the properties and motion of fluids, and their powers of reſiſtance, with the motion of bodies through ſuch reſiſting mediums, thoſe reſiſtances being in the ratio of any powers of the velocities; and the motions being either made in right lines or curves, or vibrating like pendulums. And here he demonſtrates ſuch principles as entirely overthrow the doctrine of Des Cartes's vortices, which was the faſhionable ſyſtem in his time; concluding the book with theſe words: "So that the hypotheſis of vortices is utterly irreconcileable with aſtronomical phenomena, and rather ſerves to perplex than explain the heavenly motions. How theſe motions are performed in free ſpaces without vortices, may be underſtood by the firſt book; and I ſhall now more fully treat of it in the following book Of the Syſtem of the World."—In this ſecond book he makes great uſe of the doctrine of Fluxions, then lately invented; for which purpoſe he lays down the principles of that doctrine in the 2d Lemma, in theſe words: "The moment of any Genitum is equal to the moments of each of the generating ſides drawn into the indices of the powers of thoſe ſides, and into their coefficients continually:" which rule he demonſtrates, and then adds the following ſcholium concerning the invention of that doctrine: "In a letter of mine, ſays he, to Mr. J. Collins, dated December 10, 1672, having deſcribed a method of tangents, which I ſuſpected to be the ſame with Sluſius's method, which at that time was not made public; I ſubjoined theſe words: 'This is one particular, or rather a corollary, of a general method which extends itſelf without any troubleſome calculation, not only to the drawing of tangents to any curve lines, whether geometrical or mechanical, or any how reſpecting right lines or other curves, but alſo to the reſolving other abſtruſer kinds of problems about the curvature, areas, lengths, centres of gravity of curves, &c; nor is it (as Hudden's method de Maximis & Minimis) limited to equations which are free from ſurd quantities. This method I have interwoven with that other of working in equations, by reducing them to infinite ſeries.' So far that letter. And theſe laſt words relate to a Treatiſe I compoſed on that ſubject in the year 1671." Which, at leaſt, is therefore the date of the invention of the doctrine of Fluxions.

On entering upon the 3d book of the Principia, Newton briefly recapitulates the contents of the two former books in theſe words: "In the preceding books I have laid down the principles of philoſophy; principles not philoſophical, but mathematical; ſuch, to wit, as we may build our reaſonings upon in philoſophical enquiries. Theſe principles are, the laws and conditions of certain motions, and powers or forces, which chiefly have reſpect to philoſophy. But leſt they ſhould have appeared of themſelves dry and barren, I have illuſtrated them here and there with ſome philoſophical ſcholiums, giving an account of ſuch things, as are of a more general nature, and which philoſophy ſeems chiefly to be founded on; ſuch as the denſity and the reſiſtance of bodies, ſpaces void of all matter, and the motion of light and ſounds. It remains, he adds, that from the ſame principles I now demonſtrate the frame of the ſyſtem of the world. Upon this ſubject, I had indeed compoſed the 3d book in a popular method, that it might be read by many. But afterwards conſidering that ſuch as had not ſufficiently entered into the principles could not eaſily diſcern the ſtrength of the conſequences, nor lay aſide the prejudices to which they had been many years accuſtomed; therefore to prevent the diſputes which might

might be raiſed upon ſuch accounts, I choſe to reduce the ſubſtance of that book into the form of propoſitions, in the mathematical way, which ſhould be read by thoſe only, who had firſt made themſelves maſters of the principles eſtabliſhed in the preceding books."

As a neceſſary preliminary to this 3d part, Newton lays down the following rules for reaſoning in natural philoſophy:

1. We are to admit no more cauſes of natural things, than ſuch as are both true and ſufficient to explain their natural appearances.

2. Therefore to the ſame natural effects we muſt always aſſign, as far as poſſible, the ſame cauſes.

3. The qualities of bodies which admit neither intenſion nor remiſſion of degrees, and which are found to belong to all bodies within the reach of our experiments, are to be eſteemed the univerſal qualities of all bodies whatſoever.

4. In experimental philoſophy, we are to look upon propoſitions collected by general induction from phenomena, as accurately or very nearly true, notwithſtanding any contrary hypotheſes that may be imagined, till ſuch time as other phenomena occur, by which they may either be made more accurate, or liable to exceptions.

The phenomena firſt conſidered are, 1. That the ſatellites of Jupiter, by radii drawn to his centre, deſcribe areas proportional to the times of deſcription; and that their periodic times, the fixed ſtars being at reſt, are in the ſeſquiplicate ratio of their diſtances from that centre. 2. The ſame thing is likewiſe obſerved of the phenomena of Saturn. 3. The five primary planets, Mercury, Venus, Mars, Jupiter, and Saturn, with their ſeveral orbits, encompaſs the ſun. 4. The fixed ſtars being ſuppoſed at reſt, the periodic times of the ſaid five primary planets, and of the earth, about the ſun, are in the ſeſquiplicate proportion of their mean diſtances from the ſun. 5. The primary planets, by radii drawn to the earth, deſcribe areas no ways proportional to the times: but the areas which they deſcribe by radii drawn to the ſun are proportional to the times of deſcription. 6. The moon, by a radius drawn to the centre of the earth, deſcribes an area proportional to the time of deſcription. All which phenomena are clearly evinced by aſtronomical obſervations. The mathematical demonſtrations are next applied by Newton in the following propoſitions.

Prop. 1. The forces by which the ſatellites of Jupiter are continually drawn off from rectilinear motions, and retained in their proper orbits, tend to the centre of that planet; and are reciprocally as the ſquares of the diſtances of thoſe ſatellites from that centre.

Prop. 2. The ſame thing is true of the primary planets, with reſpect to the ſun's centre.

Prop. 3. The ſame thing is alſo true of the moon, in reſpect of the earth's centre.

Prop. 4. The moon gravitates towards the earth; and by the force of gravity is continually drawn off from a rectilinear motion, and retained in her orbit.

Prop. 5. The ſame thing is true of all the other planets, both primary and ſecondary, each with reſpect to the centre of its motion.

Prop. 6. All bodies gravitate towards every planet; and the weights of bodies towards any one and the ſame planet, at equal diſtances from its centre, are proportional to the quantities of matter they contain.

Prop. 7. There is a power of gravity tending to all bodies, proportional to the ſeveral quantities of matter which they contain.

Prop. 8. In two ſpheres mutually gravitating each towards the other, if the matter in places on all ſides, round about and equidiſtant from the centres, be ſimilar; the weight of either ſphere towards the other, will be reciprocally as the ſquare of the diſtance between their centres.—Hence are compared together the weights of bodies towards different planets: hence alſo are diſcovered the quantities of matter in the ſeveral planets: and hence likewiſe are found the denſities of the planets.

Prop. 9. The force of gravity, in parts downwards from the ſurface of the planets towards their centres, decreaſes nearly in the proportion of the diſtances from thoſe centres.

Theſe, and many other propoſitions and corollaries, are proved or illuſtrated by a great variety of experiments, in all the great points of phyſical aſtronomy; ſuch as, That the motions of the planets in the heavens may ſubſiſt an exceeding long time:—That the centre of the ſyſtem of the world is immoveable:—That the common centre of gravity of the earth, the ſun, and all the planets, is immoveable:—That the ſun is agitated by a perpetual motion, but never recedes far from the common centre of gravity of all the planets:—That the planets move in ellipſes which have their common focus in the centre of the ſun; and, by radii drawn to that centre, they deſcribe areas proportional to the times of deſcription:—The aphelions and nodes of the orbits of the planets are fixt:—To find the aphelions, eccentricities, and principal diameters of the orbits of the planets:—That the diurnal motions of the planets are uniform, and that the libration of the moon ariſes from her diurnal motion:—Of the proportion between the axes of the planets and the diameters perpendicular to thoſe axes:—Of the weights of bodies in the different regions of our earth:—That the equinoctial points go backwards, and that the earth's axis, by a nutation in every annual revolution, twice vibrates towards the ecliptic, and as often returns to its former poſition:—That all the motions of the moon, and all the inequalities of thoſe motions, follow from the principles above laid down:—Of the unequal motions of the ſatellites of Jupiter and Saturn:—Of the flux and reflux of the ſea, as ariſing from the actions of the ſun and moon:—Of the forces with which the ſun diſturbs the motions of the moon; of the various motions of the moon, of her orbit, variation, inclinations of her orbit, and the ſeveral motions of her nodes:—Of the tides, with the forces of the ſun and moon to produce them:—Of the figure of the moon's body:—Of the preceſſion of the equinoxes:—And of the motions and trajectory of comets. The great author then concludes with a General Scholium, containing reflections on the principal parts of the great and beautiful ſyſtem of the univerſe, and of the infinite, eternal Creator and Governor of it.

"The hypotheſis of vortices, ſays he, is preſſed with

with many difficulties. That every planet by a radius drawn to the ſun may deſcribe areas proportional to the times of deſcription, the periodic times of the ſeveral parts of the vortices ſhould obſerve the duplicate proportion of their diſtances from the ſun. But that the periodic times of the planets may obtain the ſeſquiplicate proportion of their diſtances from the ſun, the periodic times of the parts of the vortex ought to be in the ſeſquiplicate proportion of their diſtances. That the ſmaller vortices may maintain their leſſer revolutions about Saturn, Jupiter, and other planets, and ſwim quietly and undiſturbed in the greater vortex of the ſun, the periodic times of the parts of the ſun's vortex ſhould be equal. But the rotation of the ſun and planets about their axes, which ought to correſpond with the motions of their vortices, recede far from all theſe proportions. The motions of the comets are exceeding regular, are governed by the ſame laws with the motions of the planets, and can by no means be accounted for by the hypotheſis of vortices. For comets are carried with very eccentric motions through all parts of the heavens indifferently, with a freedom that is incompatible with the notion of a vortex.

"Bodies, projected in our air, ſuffer no reſiſtance but from the air. Withdraw the air, as is done in Mr. Boyle's vacuum, and the reſiſtance ceaſes. For in this void a bit of fine down and a piece of ſolid gold deſcend with equal velocity. And the parity of reaſon muſt take place in the celeſtial ſpaces above the earth's atmoſphere; in which ſpaces, where there is no air to reſiſt their motions, all bodies will move with the greateſt freedom; and the planets and comets will conſtantly purſue their revolutions in orbits given in kind and poſition, according to the laws above explained. But though theſe bodies may indeed perſevere in their orbits by the mere laws of gravity, yet they could by no means have at firſt derived the regular poſition of the orbits themſelves from thoſe laws.

"The ſix primary planets are revolved about the ſun, in circles concentric with the ſun, and with motions directed towards the ſame parts, and almoſt in the ſame plane. Ten moons are revolved about the earth, Jupiter and Saturn, in circles concentric with them, with the ſame direction of motion, and nearly in the planes of the orbits of thoſe planets. But it is not to be conceived that mere mechanical cauſes could give birth to ſo many regular motions: ſince the comets range over all parts of the heavens, in very eccentric orbits. For by that kind of motion they paſs eaſily through the orbs of the planets, and with great rapidity; and in their aphelions, where they move the ſloweſt, and are detained the longeſt, they recede to the greateſt diſtances from each other, and thence ſuffer the leaſt diſturbance from their mutual attractions. This moſt beautiful ſyſtem of the ſun, planets, and comets, could only proceed from the counſel and dominion of an intelligent and powerful Being. And if the fixed ſtars are the centres of other like ſyſtems, theſe being formed by the like wiſe counſel, muſt be all ſubject to the dominion of one; eſpecially, ſince the light of the fixed ſtars is of the ſame nature with the light of the ſun, and from every ſyſtem light paſſes into all the other ſyſtems. And leſt the ſyſtem of the fixed ſtars ſhould, by their gravity, fall on each other mutually, he hath placed thoſe ſyſtems at immenſe diſtances one from another."

Then, after a truly pious and philoſophical deſcant on the attributes of the Being who could give exiſtence and continuance to ſuch prodigious mechaniſm, and with ſo much beautiful order and regularity, the great author proceeds,

"Hitherto we have explained the phenomena of the heavens and of our ſea, by the power of gravity, but have not yet aſſigned the cauſe of this power. This is certain, that it muſt proceed from a cauſe that penetrates to the very centres of the ſun and planets, without ſuffering the leaſt diminution of its force; that operates, not according to the quantity of the ſurfaces of the particles upon which it acts, (as mechanical cauſes uſe to do,) but according to the quantity of the ſolid matter which they contain, and propagates its virtue on all ſides, to immenſe diſtances, decreaſing always in the duplicate proportion of the diſtances. Gravitation towards the ſun, is made up out of the gravitations towards the ſeveral particles of which the body of the ſun is compoſed; and in receding from the ſun, decreaſes accurately in the duplicate proportion of the diſtances, as far as the orb of Saturn, as evidently appears from the quieſcence of the aphelions of the planets; nay, and even to the remoteſt aphelions of the comets, if thoſe aphelions are alſo quieſcent. But hitherto I have not been able to diſcover the cauſe of thoſe properties of gravity from phenomena, and I frame no hypotheſes. For whatever is not deduced from the phenomena, is to be called an hypotheſis; and hypotheſes, whether metaphyſical or phyſical, whether of occult qualities or mechanical, have no place in experimental philoſophy. In this philoſophy particular propoſitions are inferred from the phenomena, and afterwards rendered general by induction. Thus it was that the impenetrability, the mobility, and the impulſive force of bodies, and the laws of motion and of gravitation, were diſcovered. And to us it is enough, that gravity does really exiſt, and act according to the laws which we have explained, and abundantly ſerves to account for all the motions of the celeſtial bodies, and of our ſea.

"And now we might add ſomething concerning a certain moſt ſubtle ſpirit, which pervades and lies hid in all groſs bodies, by the force and action of which ſpirit, the particles of bodies mutually attract one another at near diſtances, and cohere, if contiguous, and electric bodies operate to greater diſtances, as well repelling as attracting the neighbouring corpuſcles; and light is emitted, reflected, refracted, inflected, and heats bodies; and all ſenſation is excited, and the members of animal bodies move at the command of the will, namely, by the vibrations of this ſpirit, mutually propagated along the ſolid filaments of the nerves, from the outward organs of ſenſe to the brain, and from the brain into the muſcles. But theſe are things that cannot be explained in few words, nor are we furniſhed with that ſufficiency of experiments which is required to an accurate determination and demonſtration of the laws by which this electric and elaſtic ſpirit operates."

NICHE, a cavity, or hollow part, in the thickneſs of a wall, to place a figure or ſtatue in.

NICOLE (Francis), a very celebrated French mathematician, was born at Paris December the 23d, 1683. His early attachment to the mathematics induced M. Montmort to take the charge of his education: and he opened out to him the way to the higher geometry. He firſt became publicly remarkable by detecting the fallacy of a pretended quadrature of the circle. This quadrature a M. Mathulon ſo aſſuredly thought he had diſcovered, that he depoſited, in the hands of a public notary at Lyons, the ſum of 3000 livres, to be paid to any perſon who, in the judgment of the Academy of Sciences, ſhould demonſtrate the falſity of his ſolution. M. Nicole, piqued at this challenge, undertook the taſk, and expoſing the paralogiſm, the Academy's judgment was, that Nicole had plainly proved that the rectilineal figure which Mathulon had given as equal to the circle, was not only unequal to it, but that it was even greater than the polygon of 32 ſides circumſcribed about the circle.—The prize of 3000 livres, Nicole preſented to the public hoſpital of Lyons.

The Academy named Nicole, Eleve-Mechanician, March 12, 1707; Adjunct in 1716, Aſſociate in 1718, and Penſioner in 1724; which he continued till his death, which happened the 18th of January 1758, at 75 years of age.

His works were all inſerted in the different volumes of the Memoirs of the Academy of Sciences; and are as follow:

1. A General Method for determining the Nature of Curves formed by the Rolling of other Curves upon any Given Curve; in the volume for the year 1707.

2. A General Method for Rectifying all Roulets upon Right and Circular Baſes; 1708.

3. General Method of determining the Nature of thoſe Curves which cut an Infinity of other Curves given in Poſition, cutting them always in a Conſtant Angle; 1715.

4. Solution of a Problem propoſed by M. de Lagny; 1716.

5. Treatiſe of the Calculus of Finite Differences; 1717.

6. Second Part of the Calculus of Finite Differences; 1723.

7. Second Section of ditto; 1723.

8. Addition to the two foregoing papers; 1724.

9. New Propoſition in Elementary Geometry; 1725.

10. New Solution of a Problem propoſed to the Engliſh Mathematicians, by the late M. Leibnitz; 1725.

11. Method of Summing an Infinity of New Series, which are not ſummable by any other known method; 1727.

12. Treatiſe of the Lines of the Third Order, or the Curves of the Second Kind; 1729.

13. Examination and Reſolution of ſome Queſtions relating to Play; 1730.

14. Method of determining the Chances at Play.

15. Obſervations upon the Conic Sections; 1731.

16. Manner of generating in a Solid Body, all the Lines of the Third Order; 1731.

17. Manner of determining the Nature of Roulets formed upon the Convex Surface of a Sphere; and of determining which are Geometric, and which are Rectifiable; 1732.

18. Solution of a Problem in Geometry; 1732.

19. The Uſe of Series in reſolving many Problems in the Inverſe Method of Tangents; 1737.

20. Obſervations on the Irreducible Caſe in Cubic Equations; 1738.

21. Obſervations upon Cubic Equations; 1738.

22. On the Triſection of an Angle; 1740.

23. On the Irreducible Caſe in Cubic Equations; 1741.

24. Addition to ditto; 1743.

25. His Laſt Paper upon the ſame; 1744.

26. Determination, by Incommenſurables and Decimals, the Values of the Sides and Areas of the Series in a Double Progreſſion of Regular Polygons, inſcribed in and circumſcribed about a Circle; 1747.

NIEUWENTYT (Bernard), an eminent Dutch philoſopher and mathematician, was born on the 10th of Auguſt 1654, at Weſtgraafdyk in North Holland, where his father was miniſter. He diſcovered very early a good genius and a ſtrong inclination for learning; which was carefully improved by a ſuitable education. He had alſo that prudence and ſagacity, which led him to purſue literature by ſure and proper ſteps, acquiring a kind of maſtery in one ſcience before he proceeded to another. His father had deſigned him for the miniſtry; but ſeeing his inclination did not lie that way, he prudently left him to purſue the bent of his genius. Accordingly, young Nieuwentyt apprehending that nothing was more uſeful than fixing his imagination and forming his judgment well, applied himſelf early to logic, and the art of reaſoning juſtly, in which he grounded himſelf upon the principles of Des Cartes, with whoſe philoſophy he was greatly delighted. From thence he proceeded to the mathematics, in which he made a conſiderable proficiency; though the application he gave to that branch of learning did not hinder him from ſtudying both law and phyſic. In fact he ſucceeded in all theſe ſciences ſo well, as deſervedly to acquire the character of a good philoſopher, a great mathematician, an expert phyſician, and an able and juſt magiſtrate.

Although he was naturally of a grave and ſerious diſpoſition, yet he was very affable and agreeable in converſation. His engaging manner procured the affection of every one; and by this means he often drew over to his opinion thoſe who before differed very widely from him. Thus accompliſhed, he acquired a great eſteem and credit in the council of the town of Purmerende, where he reſided; as he did alſo in the ſtates of that province, who reſpected him the more, inaſmuch as he never engaged in any cabals or factions, in order to ſecure it; regarding in his conduct, an open, honeſt, upright behaviour, as the beſt ſource of ſatisfaction, and relying ſolely on his merit. In fact, he was more attentive to cultivate the ſciences, than eager to obtain the honours of the government; contenting himſelf with being counſellor and burgomaſter, without courting or accepting any other poſts, which might interfere with his ſtudies, and draw him too much out of his library.—Nieuwentyt died the 7th of May 1730, at 76 years

years of age—having been twice married.—He was author of ſeveral works, in the Latin, French, and Dutch languages, the principal of which are the following:

1. A Treatiſe in Dutch, *proving the Exiſtence of God by the Wonders of Nature*; a much eſteemed work, and went through many editions. It was tranſlated alſo into ſeveral languages, as the French, and the Engliſh, under the title of, *The Religious Philoſopher, &c.*

2. A Refutation of Spinoza, in the Dutch language.

3. *Analyſis Infinitorum*; 1695, 4to.

4. *Conſiderationes ſecundæ circa Calculi Differentialis Principia*; 1696, 8vo.—In this work he attacked Leibnitz, and was anſwered by John Bernoulli and James Herman.

5. A Treatiſe on the New Uſe of the Tables of Sines and Tangents.

6. A Letter to Bothnia or Burmania, upon the Subject of Meteors.

NIGHT, that part of the natural day, during which the ſun is below the horizon: though ſometimes it is underſtood that the twilight is referred to the day, or time the ſun is above the horizon; the remainder only being the Night.

Under the equator, the Nights, in the former ſenſe, are always equal to the days; each being 12 hours long. But under the poles, the Night continues half a year.—The ancient Gauls and Germans divided their time not by days, but Nights; as appears from Cæſar and Tacitus; alſo the Arabs and the Icelanders do the ſame. The ſame may alſo be obſerved of our Saxon anceſtors: whence our cuſtom of ſaying, Sevennight, Fortnight, &c.

NOCTILUCA, a ſpecies of phoſphorus, ſo called becauſe it ſhines in the night, without any light being thrown on it: ſuch is the phoſphorus made of urine. By which it ſtands diſtinguiſhed from ſome other ſpecies of phoſphorus, which require to be expoſed to the ſunbeams before they will ſhine; as the Bononian-ſtone, &c.—Mr. Boyle has a particular Treatiſe on this ſubject.

NOCTURNAL *Arch*, is the arch of a circle deſcribed by the ſun, or a ſtar, in the night.

NOCTURNAL, or NOCTURLABIUM, denotes an inſtrument, chiefly uſed at ſea, to take the altitude or depreſſion of the pole ſtar, and ſome other ſtars about the pole, for finding the latitude, and the hour of the night.

There are ſeveral kinds of this inſtrument; ſome of which are projections of the ſphere; ſuch as the hemiſpheres, or planiſpheres, on the plane of the equinoctial. The ſeamen commonly uſe two kinds; the one adapted to the pole ſtar and the firſt of the guards of the Little Bear; the other to the pole ſtar and the pointers of the Great Bear.

The Nocturnal conſiſts of two circular plates (fig. 15, pl. xiii) applied over each other. The greater, which has a handle to hold the inſtrument, is about 2½ inches diameter, and is divided into 12 parts, anſwering to the 12 months; alſo each month ſubdivided into every 5th day; and in ſuch manner, that the middle of the handle correſponds to that day of the year in which the ſtar here reſpected has the ſame right aſcenſion with the ſun.

When the inſtrument is fitted for two ſtars, the handle is made moveable. The upper circle is divided into 24 equal parts, for the 24 hours of the day, and each hour ſubdivided into quarters, as in the figure. Theſe 24 hours are noted by 24 teeth; to be told in the night. In the centre of the two circular plates is adjuſted a long index A, moveable upon the upper plate. And the three pieces, viz, the two circles and index, are joined by a rivet which is pierced through the centre, with a hole 2 inches in diameter, for the ſtar to be obſerved through.

To Uſe the NOCTURNAL. Turn the upper plate till the longeſt tooth, marked 12, be againſt the day of the month on the under plate; and bringing the inſtrument near the eye, ſuſpend it by the handle, with the plane nearly parallel to the equinoctial; then viewing the pole-ſtar through the hole in the centre, turn the index about till, by the edge coming from the centre, you ſee the bright ſtar or guard of the Little Bear, if the inſtrument be fitted to that ſtar: then that tooth of the upper circle, under the edge of the index, is at the hour of the night on the edge of the hour-circle: which may be known without a light, by counting the teeth from the longeſt, which is for the hour of 12.

NODATED *Hyperbola*, one, ſo called by Newton, which by turning round decuſſates or croſſes itſelf: as in the 2d, and ſeveral other ſpecies, of his Enumeratio Linearum Tertii Ordinis.

NODES, the two oppoſite points where the orbit of a planet interſects the ecliptic. That, where the planet aſcends from the ſouth to the north ſide of the ecliptic, is called the Aſcending Node, or the Dragon's Head, and marked thus ☊: and the oppoſite point, where the planet deſcends from the north to the ſouth ſide of the ecliptic, is called the Deſcending Node, or Dragon's Tail, and is thus marked ☋. Alſo the right line drawn from the one Node to the other, is called the Line of the Nodes.

By obſervation it appears that, in all the planets, the Line of the Nodes continually changes its place, its motion being *in antecedentia*; i. e. contrary to the order of the ſigns, or from eaſt to weſt; with a peculiar degree of motion for each planet. Thus, by a retrograde motion, the line of the moon's nodes completes its circuit in 18 years and 225 days, in which time the Node returns again to the ſame point of the ecliptic. Newton has not only ſhewn, that this motion ariſes from the action of the ſun, but, from its cauſe, he has with great ſkill calculated all the elements and varieties in this motion. See his Princip. lib. 3, prop. 30, 31, &c.

The moon muſt be in or near one of the Nodes to make an eclipſe either of the ſun or moon.

NODUS, or *Node*, in Dialling, denotes a point or hole in the gnomon of a dial, by the ſhadow or light of which is ſhewn, either the hour of the day in dials without furniture, or the parallels of the ſun's declination, and his place in the ecliptic, &c, in dials with furniture.

NOLLET (the Abbé JOHN ANTHONY), a conſiderable French philoſopher, and a member of moſt of the philoſophical ſocieties and academies of Europe, was born at Pimpré, in the diſtrict of Noyon, the 19th of November 1700. From the profound retreat, in which the mediocrity of his fortune obliged him to live, his reputation continually increaſed from day to day.

M. Dufay aſſociated him in his Electrical Reſearches; and M. de Reaumur reſigned to him his laboratory. It was under theſe maſters that he developed his talents. M. Dufay took him along with him in a journey he made into England; and Nollet profited ſo well of this opportunity, as to inſtitute a friendly and literary correſpondence with ſome of the moſt celebrated men in this country.

The king of Sardinia gave him an invitation to Turin, to perform a courſe of experimental philoſophy to the duke of Savoy. From thence he travelled into Italy, where he collected ſome good obſervations concerning the natural hiſtory of the country.

In France he was maſter of philoſophy and natural hiſtory to the royal family; and profeſſor royal of experimental philoſophy to the college of Navarre, and to the ſchools of artillery and engineers. The Academy of Sciences appointed him adjunct-mechanician in 1739, aſſociate in 1742, and penſioner in 1757. Nollet died the 24th of April 1770, regretted by all his friends, but eſpecially by his relations, whom he always ſuccoured with an affectionate attention. The works publiſhed by Nollet, are the following:

1. Recueils de Lettres ſur l'Electricité; 1753, 3 vols in 12mo.

2. Eſſai ſur l'Electricité des Corps; 1 vol. in 12mo.

3. Recherches ſur les Cauſes particulieres des Phenomenes Electriques; 1 vol. in 12mo.

4. L'Art des Expériences; 1770, 3 vols in 12mo.

His papers printed in the different volumes of the Memoirs of the Academy of Sciences, are much too numerous to be particularized here; they are inſerted in all or moſt of the volumes from the year 1740 to the year 1767 incluſive, moſtly ſeveral papers in each volume.

NONAGESIMAL, or Nonagesimal *Degree*, called alſo the Mid-heaven, is the higheſt point, or 90th degree of the ecliptic, reckoned from its interſection with the horizon at any time; and its altitude is equal to the angle that the ecliptic makes with the horizon at their interſection, or equal to the diſtance of the zenith from the pole of the ecliptic. It is much uſed in the calculation of ſolar eclipſes.

NONAGON, a figure having nine ſides and angles.—In a regular Nonagon, or that whoſe angles, and ſides, are all equal, if each ſide be 1, its area will be $6{\cdot}1818242 = \frac{2}{4}$ of the tangent of 70°, to the radius 1. See my Menſuration, p. 114, 2d edit.

NONES, in the Roman Calendar, the 5th day of the months January, February, April, June, Auguſt, September, November, and December; and the 7th of the other months March, May, July, and October: theſe laſt four months having 6 days before the Nones, and the others only four.—They had this name probably, becauſe they were always 9 days incluſively, from the firſt of the Nones to the Ides, i. e. reckoning incluſively both thoſe days.

NONIUS, or Nunez (Peter), a very eminent Portugueſe mathematician and phyſician, was born in 1497, at Alcazar in Portugal, anciently a remarkable city, known by the name of Salacia, from whence he was ſurnamed Salacienſis. He was profeſſor of mathematics in the univerſity of Coimbra, where he publiſhed ſome pieces which procured him great reputation. He was mathematical preceptor to Don Henry, ſon to king Emanuel of Portugal, and principal coſmographer to the king. Nonius was very ſerviceable to the deſigns, which this court entertained of carrying on their maritime expeditions into the Eaſt, by the publication of his book *Of the Art of Navigation*, and various other works. He died in 1577, at 80 years of age.

Nonius was the author of ſeveral ingenious works and inventions, and juſtly eſteemed one of the moſt eminent mathematicians of his age. Concerning his *Art of Navigation*, father Dechales ſays, "In the year 1530, Peter Nonius, a celebrated Portugueſe mathematician, upon occaſion of ſome doubts propoſed to him by Martinus Alphonſus Sofa, wrote a Treatiſe on Navigation, divided into two books; in the firſt, he anſwers ſome of thoſe doubts, and explains the nature of Loxodromic lines. In the ſecond book, he treats of rules and inſtruments proper for navigation, particularly ſea-charts, and inſtruments ſerving to find the elevation of the pole; but ſays he is rather obſcure in his manner of writing."—Furetiere, in his Dictionary, takes notice that Peter Nonius was the firſt who, in 1530, invented the angles which the Loxodromic curves make with each meridian, calling them in his language Rhumbs, and which he calculated by ſpherical triangles.—Stevinus acknowledges, that Peter Nonius was ſcarce inferior to the very beſt mathematicians of the age. And Schottus ſays, he explained a great many problems, and particularly the mechanical problem of Ariſtotle on the motion of veſſels by oars. His Notes upon Purbach's Theory of the Planets, are very much to be eſteemed: he there explains ſeveral things, which had either not been noticed before, or not rightly underſtood.

In 1542 he publiſhed a Treatiſe on the Twilight, which he dedicated to John the 3d, king of Portugal; to which he added what Alhazen, an Arabian author, has compoſed on the ſame ſubject. In this work he deſcribes the method or inſtrument called, from him, a Nonius, a particular account of which ſee in the following article.—He corrected ſeveral mathematical miſtakes of Orontius Finæus.—But the moſt celebrated of all his works, or that at leaſt he appeared moſt to value, was his *Treatiſe of Algebra*, which he had compoſed in Portugueſe, but tranſlated it into the Caſtilian tongue, when he reſolved upon making it public, which he thought would render his book more uſeful, as this language was more generally known than the Portugueſe. The dedication, to his former pupil, prince Henry, was dated from Liſbon, Dec. 1, 1564. This work contains 341 pages in the Antwerp edition of 1567, in 8vo.

The catalogue of his works, chiefly in Latin, is as follows:

1. *De Arte Navigandi*, libri duo; 1530.
2. *De Crepuſculis*; 1542.
3. *Annotationes in Ariſtotelem.*
4. Problema Mechanicum de Motu Navigii ex Remis.
5. Annotationes in Planetarum Theorias Georgii Purbachii, &c.
6. Libro de Algebra en Arithmetica y Geometra; 1564.

NONIUS, is a name alſo erroneouſly given to the method of graduation now generally uſed in the diviſion of the ſcales of various inſtruments, and which ſhould be called Vernier, from its real inventor. The method of Nonius, ſo called from its inventor Pedro Nunez, or Nonius, and deſcribed in his treatiſe De Crepuſculis, printed at Liſbon in 1542, conſiſts in deſcribing within the ſame quadrant, 45 concentric circles, dividing the outermoſt into 90 equal parts, the next within into 89, the next into 88, and ſo on, till the innermoſt was divided into 46 only. By this means, in moſt obſervations, the plumb-line or index muſt croſs one or other of thoſe circles in or very near a point of diviſion; whence by calculation the degrees and minutes of the arch might eaſily be obtained. This method is alſo deſcribed by Nunez, in his treatiſe De Arte et Ratione Navigandi, lib. 2, cap. 6, where he imagines it was not unknown to Ptolomy. But as the degrees are thus divided unequally, and it is very difficult to attain exactneſs in the diviſion, eſpecially when the numbers, into which the arches are to be divided, are incompoſite, of which there are no leſs than nine, the method of diagonals, firſt publiſhed by Thomas Digges, Eſq. in his treatiſe Alæ ſeu Scalæ Mathematicæ, printed at Lond. in 1573, and ſaid to be invented by one Richard Chanſeler, a very ſkilful artiſt, was ſubſtituted in its ſtead. However, Nonius's method was improved at different times; but the admirable diviſion now ſo much in uſe, is the moſt conſiderable improvement of it. See VERNIER.

NORMAL, is uſed ſometimes for a perpendicular.

NORTH *Star*, called alſo the Pole-ſtar, is the laſt in the tail of the Little Bear.

NORTHERN *Signs*, are thoſe ſix that are in the north ſide of the equator; viz, Aries, Taurus, Gemini, Cancer, Leo, Virgo.

NORTHING, in Navigation, is the difference of latitude, which a ſhip makes in ſailing northwards.

NOSTRADAMUS (MICHEL), an able phyſician and celebrated aſtrologer, was born at St. Remy in Provence in the dioceſe of Avignon, December 14, 1503. His father was a notary public, and his grandfather a phyſician, from whom he received ſome tincture of the mathematics. He afterwards completed his courſes of languages and philoſophy at Avignon. From hence, going to Montpelier, he there applied himſelf to phyſic; but being forced away by the plague, he travelled through different places till he came to Bourdeaux, undertaking all ſuch patients as were willing to put themſelves under his care. This courſe occupied him five years; after which he returned to Montpelier, and was created doctor of his faculty in 1529; after which he reviſited the ſame places where he had practiſed phyſic before. At Agen he formed an acquaintance with Julius Cæſar Scaliger, and married his firſt wife; but having buried her, and two children which ſhe brought him, he quitted Agen after a reſidence of about four years. He fixed next at Marſeilles; but, his friends having provided an advantageous match for him at Salon, he repaired thither about the year 1544, and married accordingly his ſecond wife, by whom he had ſeveral children.

In 1546, Aix being afflicted with the plague, he went thither at the ſolicitation of the inhabitants, to whom he rendered great ſervice, particularly by a powder of his own invention: ſo that the town, in gratitude, gave him a conſiderable penſion for ſeveral years after the contagion ceaſed. In 1547 the city of Lyons, being viſited with the ſame diſtemper, had recourſe to our phyſician, who attended them alſo. Afterwards returning to Salon, he began a more retired courſe of life, and in this time of leiſure applied himſelf cloſely to his ſtudies. He had for a long time followed the trade of a conjurer occaſionally; and now he began to fancy himſelf inſpired, and miraculouſly illuminated with a proſpect into futurity. As faſt as theſe illuminations had diſcovered to him any future event, he entered it in writing, in ſimple proſe, though in enigmatical ſentences; but reviſing them afterwards, he thought the ſentences would appear more reſpectable, and ſavour more of a prophetic ſpirit, if they were expreſſed in verſe. This opinion determined him to throw them all into quatrains, and he afterward ranged them into centuries. For ſome time he could not venture to publiſh a work of this nature; but afterwards perceiving that the time of many events foretold in his quatrains was very near at hand, he reſolved to print them, as he did, with a dedication addreſſed to his ſon Cæſar, an infant only ſome months old, and dated March 1, 1555. To this firſt edition, which compriſes but ſeven centuries, he prefixed his name in Latin, but gave to his ſon Cæſar the name as it is pronounced in French, Notradame.

The public were divided in their ſentiments of this work: many looked upon the author as a ſimple viſionary; by others he was accuſed of magic or the black art, and treated as an impious perſon who held a commerce with the devil; while great numbers believed him to be really endued with the ſupernatural gift of prophecy. However, Henry the 2d, and queen Catharine of Medicis, his mother, were reſolved to ſee our prophet, who receiving orders to that effect, he preſently repaired to Paris. He was very graciouſly received at court, and received a preſent of 200 crowns. He was ſent afterwards to Blois, to viſit the king's children there, and report what he ſhould be able to diſcover concerning their deſtinies. It is not known what his ſentence was; however he returned to Salon loaded with honour, and good preſents.

Animated with this ſucceſs, he augmented his work to the number of 1000 quatrains, and publiſhed it with a dedication to the king in 1558. That prince dying the next year of a wound which he received at a tournament, our prophet's book was immediately conſulted; and this unfortunate event was found in the 35th quatrain of the firſt century, which runs thus in the London edition of 1672:

Le Lion jeune le vieux ſurmontera,
En champ bellique, par ſingulier duelle,
Dans cage d'or l'œil il lui crevera,
Deux playes une, puis mourir mort cruelle.

In

In Engliſh thus, from the ſame edition:

The young Lion ſhall overcome the old one,
In martial field by a ſingle duel,
In a golden cage he ſhall put out his eye,
Two wounds from one, then he ſhall die a cruel death.

So remarkable a prediction added new wings to his fame; and he was honoured ſoon after with a viſit from Emanuel duke of Savoy, and the princeſs Margaret of France, his conſort. From this time Noſtradamus found himſelf even overburdened with viſitors, and his fame made every day new acquiſitions. Charles the 9th, coming to Salon, was eager above all things to have a ſight of him: Noſtradamus, who then was in waiting as one of the retinue of the magiſtrates, being inſtantly preſented to the king, complained of the little eſteem his countrymen had for him; upon which the monarch publicly declared that he would hold the enemies of Noſtradamus to be his enemies, and deſired to ſee his children. Nor did that prince's favour ſtop here; in paſſing, not long after, through the city of Arles, he ſent for Noſtradamus, and preſented him with a purſe of 200 crowns, together with a brevet, conſtituting him his phyſician in ordinary, with the ſame appointment as the reſt. But our prophet enjoyed theſe honours only a ſhort time, as he died 16 months after, viz, July 2, 1566, at Salon, being then in his grand climacteric, or 63d year.—He had publiſhed ſeveral other pieces, chiefly relating to medicine.

He left three ſons and three daughters. Cæſar the eldeſt ſon was born at Salon in 1555, and died in 1629: he left a manuſcript, giving an account of the moſt remarkable events in the hiſtory of Provence, from 1080 to 1494, in which he inſerted the lives of the poets of that country. Theſe memoirs falling into the hands of his nephew Cæſar Noſtradamus, gentleman to the duke of Guiſe, he undertook to complete the work; and being encouraged by the eſtates of the country, he carried the account up to the Celtic Gauls: the impreſſion was finiſhed at Lyons in 1614, and publiſhed under the title of Chronique de l'Hiſtoire de Provence.—The ſecond ſon, John, exerciſed with reputation the buſineſs of a proctor in the parliament of Provence.—He wrote the Lives of the Ancient Provençal Poets, called Troubadours, and the work was printed at Lyons in 1575, 8vo.—The youngeſt ſon it is ſaid undertook the trade of peeping into futurity after his father.

NOTATION, is the repreſenting of numbers, or any other quantities, by Notes, characters, or marks.

The choice of arithmetical, and other, characters, is arbitrary; and hence they are various in various nations: the figures 0, 1, 2, 3, &c, in common uſe, are derived from the Arabs and Indians, from whom they have their name, and the Notation by them, which forms the decimal or decuple ſcale, is perhaps the moſt convenient of any for arithmetical computations.

The Greeks, Hebrews, and other eaſtern nations, as alſo the Romans, expreſſed numbers by the letters of their common alphabet. See CHARACTER.

In Algebra, the quantities are repreſented moſtly by the letters of the alphabet, &c; and that as early as the time of Diophantus. See ALGEBRA.

NOTES, in Muſic, are characters which mark the tones, i. e. the elevations and fallings of the voice, or ſound, and the ſwiftneſs or ſlowneſs of its motions, &c; and theſe have undergone various alterations and improvements, before they arrived at their preſent ſtate of perfection.

NOVEMBER, the eleventh month in the Julian year, but the ninth in the year of Romulus, beginning with March; whence its name. In this month, which contains 30 days, the ſun enters the ſign ♐, viz, uſually about the 21ſt day of the month.

NUCLEUS, the kernel, is uſed by Hevelius, and ſome other aſtronomers, for the body of a comet, which others call its head, as diſtinguiſhed from its tail, or beard.

NUCLEUS is alſo uſed by ſome writers for the central parts of the earth, and other planets, which they ſuppoſe firmer, and as it were ſeparated from them, conſidered as a cortex or ſhell.

NUEL, the ſame as NEWEL of a Staircaſe.

NUMBER, a collection or aſſemblage of ſeveral units, or ſeveral things of the ſame kind; as 2, 3, 4, &c, excluſive of the number 1: which is Euclid's definition of Number.—Stevinus defines Number as that by which the quantity of anything is expreſſed: agreeably to which Newton conceives a Number to conſiſt, not in a multitude of units, as Euclid defines it, but in the abſtract ratio of a quantity of any kind to another quantity of the ſame kind, which is accounted as unity: and in this ſenſe, including all theſe three ſpecies of Number, viz, Integers, Fractions, and Surds.

Wolfius defines Number to be ſomething which refers to unity, as one right line refers to another. Thus, aſſuming a right line for unity, a Number may likewiſe be expreſſed by a right line. And in this way alſo Des Cartes conſiders numbers as expreſſed by lines, where he treats of the arithmetical operations as performed by lines, in the beginning of his Geometry.

For the manner of characterizing NUMBERS, ſee NOTATION. And

For reading and expreſſing NUMBERS in combination, ſee NUMERATION.

Mathematicians conſider Number under a great many circumſtances, and different relations, accidents, &c.

NUMBERS, *Abſolute*, *Abſtract*, *Abundant*, *Amicable*, *Applicate*, *Binary*, *Cardinal*, *Circular*, *Compoſite*, *Concrete*, *Defective*, *Fractional*, *Homogeneal*, *Irrational* or *Surd*, *Linear* or *Mixt*, *Ordinal*, *Polygonal*, *Prime*, *Pyramidal*, *Rational*, *Similar*, &c, ſee the reſpective adjectives.

Broken NUMBERS, or Fractions, are certain parts of unity, or of ſome other Number.

Cubic NUMBER, is the product of a ſquare Number multiplied by its root, or the continual product of a Number twice multiplied by itſelf;

as the Numbers - - 1, 8, 27, 64, 125, &c,
which are the cubes of - 1, 2, 3, 4, 5, &c.

This ſeries of the cubes of the ordinal Numbers, may be raiſed by addition only, viz, adding always the differences; as was firſt ſhewn by Peletarius, at the end of his Algebra, firſt printed in 1558, where he gives a table of the ſquares and Cubes of the firſt 140 numbers. See CUBE.

Every Cubic Number whoſe root is leſs than 6, viz, the Cubic Numbers 1, 8, 27, 64, 125, being divided by 6, the remainder is the root itſelf:

Thus,

Thus,

$\frac{8}{8} = 0\frac{1}{6}$; $\frac{9}{8} = 1\frac{2}{6}$; $\frac{27}{8} = 4\frac{3}{8}$; $\frac{64}{8} = 10\frac{4}{8}$; $\frac{125}{8} = 20\frac{5}{6}$;

where the remainders, or the numerators of the ſmall fractions, are 0, 1, 2, 3, 4, 5, the ſame as the roots of the Cubes 0, 1, 8, 27, 64, 125. After theſe, the next ſix Cubic Numbers being divided by 6, the remainders will be reſpectively the ſame arithmetical ſeries, viz - - - 0, 1, 2, 3, 4, 5;
to each of which adding 6, gives 6, 7, 8, 9, 10, 11,
for the roots of the next ſix cubes 216, 343, &c.

Then, again dividing the next ſet of ſix Cubic Numbers, viz, - - 1728, 2197, &c,
by 6, the remainders are again the ſame ſeries, viz, 0, 1, 2, 3, 4, 5,
to each of which adding 12, gives 12, 13, 14, 15, 16, 17, for the roots of the ſaid next ſix cubes. And ſo on in infinitum, the ſeries of remainders 0, 1, 2, 3, 4, 5, continually recurring, and to each ſet of theſe remainders the reſpective Numbers 0, 6, 12, 18, 24, &c, being added, the ſums will be the whole ſeries of roots, 0, 1, 2, 3, 4, 5, 6, &c.

M. de la Hire, from conſidering this property of the Number 6, with regard to Cubic Numbers, found that all other Numbers, raiſed to any power whatever, had each their diviſor, which had the ſame effect with regard to them, that 6 has with regard to Cubes. And the general rule he has diſcovered is this: if the exponent of the power of a number be even, i. e. if that number be raiſed to the 2d, 4th, 6th, &c power, it muſt be divided by 2, then the remainder added to 2, or to a multiple of 2, gives the root of the Number correſponding to its power, i. e. the 2d, or 4th, &c, root. But if the exponent of the power of the Number be uneven, viz the 3d, 5th, 7th, &c power, the double of that exponent ſhall be the diviſor, which ſhall have the property here required.

A Determinate NUMBER, is that which is referred to ſome given unit; as a ternary or three.

An *Even* NUMBER, is that which may be divided into two equal parts, without remainder or fraction, as the Numbers 2, 4, 6, 8, 10, &c.—The ſums, differences, products, and powers of Even Numbers, are alſo Even Numbers.

An *Evenly-Even* NUMBER, is ſuch as being divided by an even Number, the quotient is alſo an Even Number without a remainder: as 16, which divided by 8 gives 2 for the quotient.

An *Unevenly-Even* NUMBER, is ſuch as being divided by an Even Number, the quotient is an Uneven one: as 20, which divided by 4, gives 5 for the quotient.

Figurate or *Figural* NUMBERS, are certain ranks of Numbers found by adding together firſt a rank of units, which is the firſt order, which gives the 2d order; then theſe added give the 3d order; and ſo on. Hence, the ſeveral orders of Figurate Numbers, are as follow:

Firſt order	-	1 . 1 . 1 . 1 . 1 . &c.
2d order	-	1 . 2 . 3 . 4 . 5 . &c.
3d order	-	1 . 3 . 6 . 10 . 15 . &c.
4th order	-	1 . 4 . 10 . 20 . 35 . &c.
5th order	-	1 . 5 . 15 . 35 . 70 . &c.

The firſt order conſiſts all of equals, and the 2d order of the natural arithmetical progreſſion; the 3d order is alſo called triangular Numbers, the 4th order pyramidals, &c.

See FIGURATE *Numbers*.

Heterogeneal NUMBERS, are ſuch as are referred to different units. As three men and 4 trees.

Homogeneal NUMBERS, are ſuch as are referred to the ſame unit. As 3 men and 4 men.

Imperfect NUMBERS, are thoſe whoſe aliquot parts added together, make either more or leſs than the whole of the number itſelf; and are diſtinguiſhed into Abundant and Defective.

Indeterminate NUMBER, is that which is referred to unity in the general; which is what we call Quantity.

Irrational or *Surd* NUMBER, is one that is not commenſurable with unity; as $\sqrt{2}$, or $\sqrt[3]{4}$, &c

Perfect NUMBER, that which is juſt equal to the ſum of its aliquot parts, added together. As, 6, 28, &c: for the aliquot parts of 6 are 1, 2, 3, whoſe ſum is the ſame 6; and the aliquot parts of 28, are 1, 2, 4, 7, 14, whoſe ſum is 28. See PERFECT *Number*.

Plane NUMBER, that which ariſes from the multiplication of two other Numbers: ſo 6 is a plane or rectangle, whoſe two ſides are 2 and 3, for $2 \times 3 = 6$.

Square NUMBER, is a Number produced by multiplying any given Number by itſelf; as the
Square Numbers - - 1, 4, 9, 16, 25, &c,
produced from the roots - 1, 2, 3, 4, 5, &c.

Every Square Number added to its root makes an even Number. See SQUARE.

Uneven NUMBER, or *Odd* NUMBER, that which differs from an even Number by one, or which cannot be divided into two equal integer parts; ſuch as 1, 3, 5, 7, &c. The ſums and differences of Uneven Numbers are even; but all the products and powers of them are Uneven Numbers. On the other hand, the ſum or difference of an even and Uneven Number are both Uneven, but their product is even.

Whole NUMBER, or *Integer*, is unit, or a collection of units.

Golden NUMBER. See GOLDEN *Number* and CYCLE.

NUMBER *of Direction*, in Chronology, ſome one of the 35 Numbers between the Eaſter limits, or between the earlieſt and lateſt day on which it can fall, i. e. between March 22 and April 25, which are 35 days; being ſo called, becauſe it ſerves as a Direction for finding Eaſter for any year; being indeed the Number that expreſſes how many days after March 21, Eaſter-day falls. Thus, Eaſter-day falling as in the firſt line below, the Number of Direction will be as on the lower line:

	March											April										
Eaſter-day,	22,	23,	24,	25,	26,	27,	28,	29,	30,	31,	1,	2,	&c.
N° of Dir.	1,	2,	3,	4,	5,	6,	7,	8,	9,	10,	11,	12,	&c

and ſo on, till the Number of Direction on the lower line be 35, which will anſwer to April 25, being the lateſt that Eaſter can happen. Therefore add 21 to the Number of Direction, and the ſum will be ſo many days in March for the Eaſter-day: if the ſum exceed 31, the exceſs will be the day of April.

To find the NUMBER *of Direction*. Enter the following table (which is adapted to the New Style), with the Dominical Letter on the left hand, and the Golden Number at the top, then where the columns meet is the

the Number of Direction for that year. See Ferguſon's Aſtron. pa. 381, ed. 8vo.

G. N.	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19
Dom. Let.																			
A	29	19	5	26	12	33	19	12	26	19	5	26	12	5	26	12	33	19	12
B	27	13	6	27	13	34	20	13	27	20	6	27	13	6	20	13	34	20	6
C	8	14	7	21	14	35	21	7	28	21	7	28	14	7	21	14	28	21	7
D	19	15	8	22	15	29	22	8	29	15	8	29	15	1	22	15	29	22	8
E	30	16	2	23	16	30	23	9	30	16	9	2	16	2	23	9	30	23	9
F	24	17	3	24	10	31	24	10	31	17	10	2	17	3	24	10	31	17	10
G	25	18	4	25	11	32	18	11	32	18	4	2	8	4	25	11	32	18	11

Thus, for the year 1790, the Dominical Letter being C, and the Golden Number 5; on the line of C, and below 5, is 14 for the Number of Direction. To this add 21, the ſum is 35 days from the 1ſt of March, which, deducting the 31 days of March, leaves 4 for the day of April, for Eaſter-day that year.

NUMERAL *Characters*. See CHARACTERS.

NUMERAL *Figures*. The antiquity of theſe in England has, for ſeveral reaſons, been ſuppoſed as high as the eleventh century; in France about the middle of the tenth century; having been introduced into both countries from Spain, where they had been brought by the Moors or Saracens. See Wallis's Algebra, pa. 9 &c, and pa. 153 of additions at the end of the ſame. See alſo Philoſ. Tranſ. numb. 439 and 475.

NUMERAL *Letters*, thoſe letters of the alphabet that are commonly uſed for figures or numbers, as I, V, X, L, C, D, M.

NUMERATION, in Arithmetic, the art of eſtimating or pronouncing any number, or ſeries of numbers.

Numbers are uſually expreſſed by the ten following characters, 1, 2, 3, 4, 5, 6, 7, 8, 9, and 0; the firſt nine denoting reſpectively the firſt nine ordinal numbers; and the laſt, or cipher 0, joined to any of the others, denotes ſo many tens. In like manner, two ciphers joined to any one of the firſt nine ſignificant figures, make it become ſo many hundreds, three ciphers make it thouſands, and ſo on.

Weigelius indeed ſhews how to number without going beyond a quaternary; i. e. by beginning to repeat at each fourth. And Leibnitz and De Lagny, in what they call their binary arithmetic, begin to repeat at every 2d place; uſing only the two figures 1 and 0. But theſe are rather matters of curioſity than any real uſe.

That the nine ſignificant figures may expreſs not only units, but alſo tens, hundreds, thouſands, &c, they have a local value given them, as hinted above; ſo that, though when alone, or in the right-hand place, they denote only units or ones, yet in the 2d place they denote tens, in the 3d place hundreds, in the 4th place thouſands, &c; as the number 5555 is five thouſand five hundred fifty and five.

Hence then, to expreſs any written number, or aſſign the proper value to each character; beginning at the right hand, divide the propoſed number into claſſes, of three characters to each claſs; and conſider two claſſes as making up a period of ſix figures or places. Then every period, of ſix figures, has a name common to all the figures in it; the firſt being primes or units; the 2d is millions; the 3d is millions-of-millions, or billions; the 4th is millions-of-millions-of-millions or trillions; and ſo on; alſo every claſs, or half-period, of three figures, is read ſeparately by itſelf, ſo many hundreds, tens, and units; only, after the left-hand half of each period, the word thouſands is added; and at the end of the 2d, 3d, 4th &c period, its common name millions, billions, &c, is expreſſed.

Thus the number 4,591, is 4 thouſand 5 hundred and 91.

The number 210,463, is 2 hundred and 10 thouſands, and 463.

The number 281,427,307, is 281 millions, 427 thouſands, and 307.

NUMERATOR, of a Fraction, is the number which ſhews how many of thoſe parts, which the integer is ſuppoſed to be divided into, are denoted by the fraction. And, in the notation the Numerator is ſet over the denominator, or number that ſhews into how many parts the integer is divided, in the fraction. So, ex. gr. $\frac{3}{4}$ denotes three-fourths, or 3 parts out of 4; where 3 is the numerator, and 4 the denominator.

NUMERICAL, NUMEROUS, or *Numeral*, ſomething that relates to number.

NUMERAL *Algebra*, is that which makes uſe of numbers, in contradiſtinction from literal algebra, or that in which the letters of the alphabet are uſed.

O.

OBE

OBELISK, a kind of quadrangular pyramid, very tall and ſlender, raiſed as an ornament in ſome public place, or to ſerve as a memorial of ſome remarkable tranſaction.

OBJ

OBJECT, ſomething preſented to the mind, by ſenſation, or by imagination. Or ſomething that affects us by its preſence, that affects the eye, ear, or ſome other of the organs of ſenſe.

The

The objects of the eye, or vision, are painted on the retina; though not there erect, but inverted, according to the laws of optics. This is eaſily ſhewn from Des Cartes's experiment, of laying bare the vitreous humour on the back part of the eye, and putting over it a bit of white paper, or the ſkin of an egg, and then placing the fore part of the eye to the hole of a darkened room. By this means there is obtained a pretty landſcape of the external objects, painted inverted on the back of the eye. In this caſe, how the Objects thus painted invertedly ſhould be ſeen erect, is matter of controverſy.

OBJECT is alſo uſed for the ſubject, or matter of an art or ſcience; being that about which it is employed or concerned.

OBJECT-*Glaſs*, of a teleſcope or microſcope, is the glaſs placed at the end of the tube which is next or towards the Object to be viewed.

To prove the goodneſs and regularity of an Object-glaſs; on a paper deſcribe two concentric circles, the one having its diameter the ſame with the breadth of the Object-glaſs, and the other half that diameter; divide the ſmaller circumference into 6 equal parts, pricking the points of diviſion through with a fine needle; cover one ſide of the glaſs with this paper, and, expoſing it to the ſun, receive the rays through theſe 6 holes upon a plane; then by moving the plane nearer to or farther from the glaſs, it will be found whether the ſix rays unite exactly together at any diſtance from the glaſs; if they do, it is a proof of the regularity and juſt form of the glaſs; and the ſaid diſtance is alſo the focal diſtance of the glaſs.

A good way of proving the excellency of an Object-glaſs, is by placing it in a tube, and trying it with ſmall eye-glaſſes, at ſeveral diſtant objects; for that Object-glaſs is always the beſt, which repreſents objects the brighteſt and moſt diſtinct, and which bears the greateſt aperture, and the moſt convex and concave eye-glaſſes, without colouring or hazineſs.

A circular Object-glaſs is ſaid to be truly centred, when the centre of its circumference falls exactly in the axis of the glaſs; and to be ill centred, when it falls out of the axis.

To prove whether Object-glaſſes be well centred, hold the glaſs at a due diſtance from the eye, and obſerve the two reflected images of a candle, varying the diſtance till the two images unite, which is the true centre point: then if this fall in the middle, or central point of the glaſs, it is known to be truly centred.

As Object-glaſſes are commonly included in cells that ſcrew upon the end of the tube of a teleſcope, it may be proved whether they be well centred, by fixing the tube, and obſerving while the cell is unſcrewed, whether the croſs-hairs keep fixed upon the ſame lines of an object ſeen through the teleſcope.

For various methods of finding the true centre of an Object-glaſs, ſee Smith's Optics, book 3, chap. 3; alſo the Philoſ. Tranſ. vol. 48, pa. 177.

OBJECTIVE *Line*, in Perſpective, is any line drawn on the geometrical plane, whoſe repreſentation is ſought for in a draught or picture.

OBJECTIVE *Plane*, in Perſpective, is any plane ſituated in the horizontal plane, whoſe perſpective repreſentation is required.

OBLATE, flatted, or ſhortened; as an Oblate ſpheroid, having its axis ſhorter than its middle diameter; being formed by the rotation of an ellipſe about the ſhorter axis.

OBLATENESS, of the earth, the flatneſs about the poles, or the diminution of the polar axis in reſpect of the equatorial. The ratio of theſe two axes has been determined in various ways; ſometimes by the meaſures of different degrees of latitude, and ſometimes by the length of pendulums vibrating ſeconds in different latitudes, &c; the reſults of all which, as well as accounts of the means of determining them, ſee under the articles EARTH and DEGREE. To what is there ſaid, may be added the following, from An Account of the Experiments made in Ruſſia concerning the Length of a Pendulum which ſwings Seconds, by Mr. Krafft, contained in the 6th and 7th volumes of the New Peterſburgh Tranſactions, for the years 1790 and 1793. Theſe experiments were made at different times, and in various parts of the Ruſſian empire: Mr. Krafft has collected and compared them, with a view to inveſtigate the conſequences that may be deduced from them. From the whole he concludes, that the length p of a pendulum, which ſwings ſeconds in any given latitude l, and in a temperature of 10 degrees of Reaumur's thermometer, may be determined by the following equation, in lines of a French foot: viz,

$$p = 439{\cdot}178 + 2{\cdot}321 \text{ fine}^2 l.$$

This expreſſion agrees, very nearly, not only with all the experiments made on the pendulum in Ruſſia, but alſo with thoſe of Mr. Graham, and thoſe of Mr. Lyons in 79° 50′ north latitude, where he found its length to be 441·38 lines.

It alſo ſhews the augmentation of gravity from the equator to the parallel of a given latitude l: for, putting g for the gravity under the equator, G for that under the pole, and z for that under the latitude l; Mr. Krafft finds $z = (1 + 0{\cdot}0052848 \text{ fine}^2 l) \times g$; and conſequently $G = 1{\cdot}0052848g$:

From this proportion of Gravity under different latitudes, Mr. Krafft deduces, that on the hypotheſis of the earth's being a homogeneous ellipſoid, its oblateneſs muſt be $\frac{1}{178}$; inſtead of $\frac{1}{230}$, which ought to be the reſult of this hypotheſis: but on adopting the ſuppoſition that the earth is a heterogeneous ellipſoid, he finds its Oblateneſs, as deduced from theſe experiments, to be $\frac{1}{297}$; which agrees with that reſulting from the meaſurement of degrees of the meridian.

This confirms an obſervation of M. De la Place, that, if the hypotheſis of the earth's homogeneity be given up, then do theory, the meaſurement of degrees of latitude, and experiments with the pendulum, all agree in their reſult with reſpect to the Oblateneſs of the earth.

OBLIQUE, aſlant, indirect, or deviating from the perpendicular. As,

OBLIQUE *Angle*, one that is not a right angle, but is either greater or leſs than this, being either obtuſe or acute.

OBLIQUE-*angled Triangle*, that whoſe angles are all oblique.

OBLIQUE *Aſcenſion*, is that point of the equinoctial which riſes with the centre of the ſun, or ſtar, or any other point of the heavens, in an Oblique ſphere.

OBLIQUE *Circle*, in the ſtereographic projection,

is any circle that is Oblique to the plane of projection.

OBLIQUE *Deſcenſion*, that point of the equinoctial which ſets with the centre of the ſun, or ſtar, or other point of the heavens in an Obliqne ſphere.

OBLIQUE *Direction*, that which is not perpendicular to a line or plane.

OBLIQUE *Force*, or Percuſſion, or *Power*, or Stroke, is that made in a direction Oblique to a body or plane. It is demonſtrated that the effect of ſuch Oblique force &c, upon the body, is to an equal perpendicular one, as the ſine of the angle of incidence is to radius.

OBLIQUE *Line*, that which makes an Oblique angle with ſome other line.

OBLIQUE *Planes*, in Dialling, are ſuch as recline from the zenith, or incline towards the horizon.

OBLIQUE *Projection*, is that where a body is projected or impelled in a line of direction that makes an oblique angle with the horizontal line.

OBLIQUE *Sailing*, in Navigation, is that part which includes the application and calculation of Oblique-angled triangles.

OBLIQUE *Sphere*, in Geography, is that in which the axis is Oblique to the horizon of a place.—In this ſphere, the equator and parallels of declination cut the horizon obliquely. And it is this obliquity that occaſions the inequality of days and nights, and the variation of the ſeaſons. See SPHERE.

OBLIQUITY, that which denotes a thing Oblique.

OBLIQUITY *of the Ecliptic*, is the angle which the ecliptic makes with the equator. See ECLIPTIC.

OBLONG, ſometimes means any figure that is longer than it is broad; but more properly it denotes a rectangle, or a right-angled parallelogram, whoſe length exceeds its breadth.

OBLONG, is alſo uſed for the quality or ſpecies of a figure that is longer than it is broad: as an Oblong ſpheroid; formed by an ellipſe revolved about its longer or tranſverſe axis; in contradiſtinction from the oblate ſpheroid, or that which is flatted at its poles, being generated by the revolution of the ellipſe about its conjugate or ſhorter axis.

OBSCURA *Camera*. See CAMERA *Obſcura*.

OBSCURA *Clara*. See CLARA *Obſcure*.

OBSERVATION, in Aſtronomy and Navigation, is the obſerving with an inſtrument ſome celeſtial phenomenon; as, the altitude of the ſun, moon, or ſtars, or their diſtances aſunder, &c. But by this term the ſeamen commonly mean only the taking the meridian altitudes, in order to find the latitude. And the finding the latitude from ſuch obſerved altitude, they call *working an obſervation*.

OBSERVATORY, a place deſtined for obſerving the heavenly bodies; or a building, uſually in form of a tower, erected on ſome eminence, and covered with a terrace, for making aſtronomical obſervations.

Moſt nations, at almoſt all times, have had their obſervatories, either public or private ones, and in various degrees of perfection. A deſcription of a great many of them may be ſeen in a diſſertation of Weidler's, De præſenti Specularum Aſtronomicarum Statu, printed in 1727, and in different articles of his Hiſtory of Aſtronomy, printed in 1741, viz, pa. 86 &c; as alſo in La Lande's Aſtronomy, the preface pa. 34. The chief among theſe are the following:

I. The Greenwich Obſervatory, or Royal Obſervatory of England. This was built and endowed in the year 1676, by order of King Charles the 2d, at the inſtance of Sir Jonas Moore, and Sir Chriſtopher Wren: the former of theſe gentlemen being Surveyor General of the Ordnance, the office of Aſtronomer Royal was placed under that department, in which it has continued ever ſince.

This obſervatory was at firſt furniſhed with ſeveral very accurate inſtruments; particularly a noble ſextant of 7 feet radius, with teleſcopic ſights. And the firſt Aſtronomer Royal, or the perſon to whom the province of obſerving was firſt committed, was Mr. John Flamſteed; a man who, as Dr. Halley expreſſes it, ſeemed born for the employment. During 14 years he watched the motions of the planets with unwearied diligence, eſpecially thoſe of the moon, as was given him in charge; that a new theory of that planet being found, ſhewing all her irregularities, the longitude might thence be determined.

In the year 1690, having provided himſelf with a mural arch of near 7 feet radius, made by his Aſſiſtant Mr. Abraham Sharp, and fixed in the plane of the meridian, he began to verify his catalogue of the fixed ſtars, which had hitherto depended altogether on the diſtances meaſured with the ſextant, after a new and very different manner, viz, by taking the meridian altitudes, and the moments of culmination, or in other words the right aſcenſion and declination. And he was ſo well pleaſed with this inſtrument, that he diſcontinued almoſt entirely the uſe of the ſextant.

Thus, in the ſpace of upwards of 40 years, the Aſtronomer Royal collected an immenſe number of good obſervations; which may be found in his Hiſtoria Cœleſtis Britannica, publiſhed in 1725; the principal part of which is the Britannic catalogue of the fixed ſtars.

Mr. Flamſteed, on his death in 1719, was ſucceeded by Dr. Halley, and he by Dr. Bradley in 1742, and this laſt by Mr. Bliſs in 1762; but none of the obſervations of theſe gentlemen have yet been given to the public.

On the demiſe of Mr. Bliſs, in 1765, he was ſucceeded by Dr. Nevil Maſkelyne, the preſent worthy aſtronomer royal, whoſe valuable obſervations have been publiſhed, from time to time, under the direction of the Royal Society, in ſeveral folio volumes.

The Greenwich Obſervatory is found, by very accurate obſervations, to lie in 51° 28′ 40″ north latitude, as ſettled by Dr. Maſkelyne, from many of his own obſervations, as well as thoſe of Dr. Bradley.

II. The Paris Obſervatory was built by Louis the 14th, in the fauxbourg St. Jaques, being begun in 1664, and finiſhed in 1672. It is a ſingular but magnificent building, of 80 feet in height, with a terrace at top; and here M. De la Hire, M. Caſſini, &c, the king's aſtronomers, have made their obſervations. Its latitude is 48° 50′ 14″ north, and its longitude 9′ 20″ eaſt of Greenwich Obſervatory.

In the Obſervatory of Paris is a cave, or pit, 170 feet deep, with ſubterraneous paſſages, for experiments that are to be made out of the reach of the ſun, eſpecially ſuch as relate to congelations, refrigerations, &c. In this cave there is an old thermometer of M. De la Hire, which ſtands always at the ſame height; thereby

ſhewing that the temperature of the place remains always the ſame. From the top of the platform to the bottom of the cave is a perpendicular well or pit, uſed formerly for experiments on the fall of bodies; being alſo a kind of long teleſcopical tube, through which the ſtars are ſeen at mid-day.

III. Tycho Brahe's Obſervatory was in the little iſland Ween, or the Scarlet Iſland, between the coaſts of Schonen and Zealand, in the Baltic ſea. This Obſervatory was not well ſituated for ſome kinds of obſervations, particularly the riſings and ſettings; as it lay too low, and was landlocked on all the points of the compaſs except three; and the land horizon being very rugged and uneven.

IV. Pekin Obſervatory. Father Le Compte deſcribes a very magnificent Obſervatory, erected and furniſhed by the late emperor of China, in his capital, at the interceſſion of ſome Jeſuit miſſionaries, chiefly father Verbieſt, whom he appointed his chief obſerver. The inſtruments here are exceeding large; but the diviſions are leſs accurate, and in ſome reſpects the contrivance is leſs commodious than in thoſe of the Europeans. The chief are, an armillary zodiacal ſphere, of 6 Paris feet diameter, an azimuthal horizon 6 feet diameter, a large quadrant 6 feet radius, a ſextant 8 feet radius, and a celeſtial globe 6 feet diameter.

V. Bramins' Obſervatory at Benares, in the Eaſt Indies, which is ſtill one of the principal ſeminaries of the Bramins or prieſts of the original Gentoos of Hindoſtan. This Obſervatory at Benares it is ſaid was built about 200 years ſince, by order of the emperor Ackbar: for as this wiſe prince endeavoured to improve the arts, ſo he wiſhed alſo to recover the ſciences of Hindoſtan; and therefore ordered that three ſuch places ſhould be erected; one at Delhi, another at Agra, and the third at Benares.

Wanting the uſe of optical glaſſes, to magnify very diſtant or very ſmall objects, theſe people directed their attention to the increaſing the ſize of their inſtruments, for obtaining the greater accuracy and number of the diviſions and ſubdiviſions in their inſtruments. Accordingly, the Obſervatory contains ſeveral huge inſtruments, of ſtone, very nicely erected and divided, conſiſting of circles, columns, gnomons, dials, quadrants, &c, ſome of them of 20 feet radius, the circle divided firſt into 360 equal parts, and ſometimes each of theſe into 20 other equal parts, each anſwering to 3′, and of about two-tenths of an inch in extent. And although theſe wonderful inſtruments have been built upwards of 200 years, the graduations and diviſions on the ſeveral arcs appear as well cut, and as accurately divided, as if they had been the performance of a modern artiſt. The execution, in the conſtruction of theſe inſtruments, exhibits an extraordinary mathematical exactneſs in the fixing, bearing, ſitting of the ſeveral parts, in the neceſſary and ſufficient ſupports to the very large ſtones that compoſe them, and in the joining and faſtening them into each other by means of lead and iron.

See a farther deſcription, and drawing, of this Obſervatory, by Sir Robert Barker, in the Philoſ. Tranſ. vol. 67, pa. 598.

Observatory *Portable*. See Equatorial.

OBTUSE *Angle*, one that is greater than a right-angle.

Obtuse-*angled Triangle*, is a triangle that has one of its angles Obtuſe: and it can have only one ſuch.

Obtuse *Cone*, or Obtuse-*Angled Cone*, one whoſe angle at the vertex, by a ſection through the axis, is Obtuſe.

Obtuse *Hyperbola*, one whoſe aſymptotes form an Obtuſe angle.

Obtuse-*angular Section of a Cone*, a name given to the hyperbola by the ancient geometricians, becauſe they conſidered this ſection only in the Obtuſe cone.

OCCIDENT, or Occidental, weſt, or weſtward, in Aſtronomy; a planet is ſaid to be Occident, when it ſets after the ſun.

Occident, in Geography, the weſtward quarter of the horizon, or that part of the horizon where the ecliptic, or the ſun's place in it, deſcends into the lower hemiſphere.

Occident *Equinoctial*, that point of the horizon where the ſun ſets, when he croſſes the equinoctial, or enters the ſign Aries or Libra.

Occident *Eſtival*, that point of the horizon where the ſun ſets at his entrance into the ſign Cancer, or in our ſummer when the days are longeſt.

Occident *Hybernal*, that point of the horizon where the ſun ſets at midwinter, when entering the ſign Capricorn.

Occidental *Horizon*. See Horizon.

OCCULT, in Geometry, is uſed for a line that is ſcarce perceivable, drawn with the point of the compaſſes, or a black-lead pencil. Occult or dry lines, are uſed in ſeveral operations; as the raiſing of plans, deſigns of building, pieces of perſpective, &c. They are to be effaced or rubbed out when the work is finiſhed.

OCCULTATION, the obſcuration, or hiding from our ſight, any ſtar or planet, by the interpoſition of the body of the moon, or of ſome other planet.—The Occultation of a ſtar by the moon, if obſerved in a place whoſe latitude and longitude are well determined, may be applied to the correction of the lunar tables; but if obſerved in a place whoſe latitude only is well known, may be applied to the determining the longitude of the place.

Circle of Perpetual Occultation. See Circle.

OCEAN, the vaſt collection of ſalt and navigable water, which encompaſſes moſt parts of the earth.

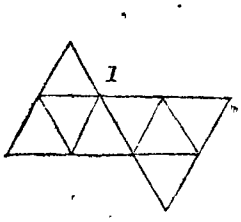
By computation it appears that the Ocean takes up conſiderably more of what we know of the terreſtrial globe, than the dry land does. This is perhaps eaſieſt known, by taking a good map of the world, and with a pair of ſciſſars clipping out all the water from the land, and weighing the two parts ſeparately: by which means it has been found, that the water occupies about two-thirds of the whole ſurface of the globe.

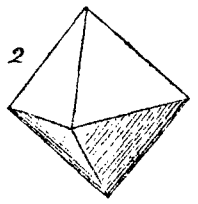
The great and univerſal Ocean is ſometimes, by geographers, divided into three parts. As, 1ſt, the Atlantic and European Ocean, lying between part of Europe, Africa, and America; 2d, the Indian Ocean, lying between Africa, the Eaſt-Indian iſlands, and New Holland; 3d, the Pacific Ocean, or great ſouth ſea, which lies between the Philippine iſlands, China, Japan, and New Holland on the weſt, and the coaſt of America on the eaſt. The Ocean alſo takes divers other names, according

cording to the different countries it borders upon: as the Britiſh Ocean, German Ocean, &c. Alſo according to the poſition on the globe; as the northern, ſouthern, eaſtern, and weſtern Oceans.

The Ocean, penetrating the land at ſeveral ſtreights, quits its name of Ocean, and aſſumes that of ſea or gulph; as the Mediterranean ſea, the Perſian gulph, &c. In very narrow places, it is called a ſtreight, &c.

OCTAEDRON, or OCTAHEDRON, one of the five regular bodies; contained under 8 equal and equilateral triangles.—It may be conceived as conſiſting of two quadrilateral pyramids joined together at their baſes.





To form an Octaedron. Join together 8 equal and equilateral triangles, as in fig. 1; then cut the lines half through, and fold the figure up by theſe cut lines, till the extreme edges meet, and form the Octaedron, as in figure 2.

In an Octaedron, if

A be the linear edge or ſide,
B its whole ſurface,
C its ſolidity, or ſolid content,
R the radius of the circumſcribed ſphere, and
r the radius of the inſcribed ſphere: Then

$$A = r\sqrt{6} = R\sqrt{2} = \frac{B\sqrt{3}}{6} = \sqrt[3]{\frac{3C\sqrt{2}}{2}}.$$

$$B = 12r^2\sqrt{3} = 4R^2\sqrt{3} = 2A^2\sqrt{3} = 6\sqrt[3]{\frac{C^2\sqrt{3}}{2}}.$$

$$C = 4r^3\sqrt{3} = \tfrac{4}{3}R^3 = \tfrac{1}{3}A^3\sqrt{2} = \frac{B\sqrt{B\sqrt{3}}}{18}.$$

$$R = r\sqrt{3} = \tfrac{1}{2}A\sqrt{2} = \sqrt{\frac{B\sqrt{3}}{12}} = \sqrt[3]{\tfrac{3}{4}C}.$$

$$r = \tfrac{1}{3}R\sqrt{3} = \tfrac{1}{6}A\sqrt{6} = \tfrac{1}{6}\sqrt{B\sqrt{3}} = \sqrt[3]{\frac{C\sqrt{3}}{12}}.$$

See my Menſuration, pa. 251 &c, 2d edition.

OCTAGON, is a figure of 8 ſides and angles; which, when theſe are all equal, is alſo called a regular one, or may be inſcribed in a circle.

If the ſide of a regular Octagon be *s*; then

Its area $= 2s^2 \times 1 + \sqrt{2} = 4{\cdot}828427s^2$; and the Radius of its circumſc. circle $= \frac{s}{\sqrt{2-\sqrt{2}}}$.

OCTAGON, in Fortification, denotes a place that has 8 ſides, or 8 baſtions.

OCTANT, the 8th part of a circle.

OCTANT, or OCTILE, means alſo an aſpect, or poſition of two planets, when their places are diſtant by the 8th part of a circle, or 45 degrees.

OCTAVE, or 8th, in Muſic, is an interval of 8 ſounds; every 8th note in the ſcale of the gamut being the ſame, as far as the compaſs of muſic requires.

Tones, or ſounds, that are Octaves to each other, or at an Octave's diſtance, are alike, or the ſame nearly as the uniſon. In this caſe, the more acute of the two makes exactly two vibrations while the deeper or graver makes but one; whence, they coincide at every two vibrations of the acuter, which, being more frequent, makes this concord more perfect than any other, and as it were an uniſon. Hence alſo, it happens, that two chords or ſtrings, of the ſame matter, thickneſs, and tenſion, but the one double the length of the other, produce the Octave.

The Octave containing in it all the other ſimple concords, and the degrees being the differences of theſe concords; it is evident, that the diviſion of the Octave comprehends the diviſion of all the reſt.

By joining therefore all the ſimple concords to a common fundamental, we have the following ſeries:

$$1 : \tfrac{5}{6} : \tfrac{4}{5} : \tfrac{3}{4} : \tfrac{2}{3} : \tfrac{3}{5} : \tfrac{1}{2}$$

Fund. 3d *l*, 3d *g*, 4th, 5th, 6th *l*, 6th *g*, 8ve.

Mr. Malcolm obſerves, that any wind inſtrument being over-blown, the ſound will riſe to an Octave, and no other concord; which he aſcribes to the perfection of the Octave, and its being next to uniſon.

Des Cartes, from an obſervation of the like kind, viz, that the ſound of a whiſtle, or organ pipe, will riſe to an Octave, if forcibly blown, concludes, that no ſound is heard, but its acute Octave ſeems ſome way to echo or reſound in the ear.

OCTILE. See OCTANT.

OCTOBER, the 8th month of the year, in Romulus's calendar; but the tenth in that of Numa, Julius Cæſar, &c, after the addition of January and February. This month contains 31 days; about the 22d of which, the ſun enters the ſign Scorpio ♏.

OCTOGON. See OCTAGON.

OCTOSTYLE, in Architecture, the face of a building adorned with 8 columns.

ODD, in Arithmetic, is ſaid of a number that is not even. The ſeries of Odd numbers is 1, 3, 5, 7, &c.

ODDLY-ODD. A number is ſaid to be Oddly-Odd, when an Odd number meaſures it by an Odd number. So 15 is a number Oddly-odd, becauſe the Odd number 3 meaſures it by the Odd number 5.

OFFING, or OFFIN, in Navigation, that part of the ſea which is at a good diſtance from ſhore; where there is deep water, and no need of a pilot to conduct the ſhip into port.

OFFSETS, in Surveying are the perpendiculars let fall, and meaſured from the ſtation lines, to the corners or bends in the hedge, fence, or boundary of any ground.

OFFSET-*Staff*, a ſlender rod or ſtaff, of 10 links, or other convenient length. Its uſe is for meaſuring the Offsets, and other ſhort lines and diſtances.

OFFWARD, in Navigation, the ſame with from the ſhore, &c.

OGEE, or OG, an ornamental moulding in the ſhape of an S; conſiſting of two members, the one concave and the other convex.

OLDENBURG (HENRY), who wrote his name ſometimes GRUBENDOL, reverſing the letters, was a learned German gentleman, and born in the Duchy of Bremen in the Lower Saxony, about the year 1626, being deſcended from the counts of Aldenburg in Weſtphalia; whence his name. During the long Engliſh parliament in the time of Charles the 1ſt, he came to England as conſul for his countrymen; in which capacity he remained at London in Cromwell's adminiſtration. But being diſcharged of that employment, he was engaged as tutor to the lord Henry Obryan, an Iriſh nobleman, whom he attended to the univerſity of Oxford; and in 1656 he entered himſelf a ſtudent in that univerſity, chiefly to have the benefit of conſulting the Bodleian library. He was afterwards appointed tutor to lord William Cavendiſh, and became intimately acquainted with Milton the poet. During his reſidence at Oxford, he became alſo acquainted with the members of that ſociety there, which gave birth to the Royal Society; and upon the foundation of this latter, he was elected a member of it: and when the Society found it neceſſary to have two ſecretaries, he was choſen aſſiſtant to Dr. Wilkins. He applied himſelf with extraordinary diligence to the duties of this office, and began the publication of the Philoſophical Tranſactions with No. 1, in 1664. In order to diſcharge this taſk with more credit to himſelf and the Society, he held a correſpondence with more than ſeventy learned perſons, and others, upon a great variety of ſubjects, in different parts of the world. This fatigue would have been inſupportable, had he not, as he told Dr. Liſter, managed it ſo as to make one letter anſwer another; and that, to be always freſh, he never read a letter before he was ready immediately to anſwer it: ſo that the multitude of his letters did not clog him, nor ever lie upon his hands. Among others, he was a conſtant correſpondent of Mr. Robert Boyle, and he tranſlated many of that ingenious gentleman's works into Latin.

About the year 1674 he was drawn into a diſpute with Mr. Hook, who complained, that the ſecretary had not done him juſtice, in the Hiſtory of the Tranſactions, with reſpect to the invention of the ſpiral ſpring for pocket watches; the conteſt was carried on with ſome warmth on both ſides, but was at length terminated to the honour of Mr. Oldenburg; for, purſuant to an open repreſentation of the affair to the Royal Society, the council thought fit to declare, in behalf of their ſecretary, that they knew nothing of Mr. Hook having printed a book intitled *Lampas*, &c; but that the publiſher of the Tranſactions had conducted himſelf faithfully and honeſtly in managing the intelligence of the Royal Society, and given no juſt cauſe for ſuch reflections.

Mr. Oldenburg continued to publiſh the Tranſactions as before, to No. 136, June 25, 1677; after which the publication was diſcontinued till the January following; when they were again reſumed by his ſucceſſor in the ſecretary's office, Mr. Nehemiah Grew, who carried them on till the end of February 1678. Mr. Oldenburg died at his houſe at Charlton, between Greenwich and Woolwich, in Kent, Auguſt 1678, and was interred there, being 52 years of age.

He publiſhed, beſides what has been already mentioned, 20 tracts, chiefly on theological and political ſubjects; in which he principally aimed at reconciling differences, and promoting peace.

OLYMPIAD, in Chronology, a revolution or period of four years, by which the Greeks reckoned their time: ſo called from the Olympic games, which were celebrated every fourth year, during 5 days, near the ſummer ſolſtice, upon the banks of the river Alpheus, near Olympia, a town of Elis. As each Olympiad conſiſted of 4 years, theſe were called the 1ſt, 2d, 3d, and 4th year of each Olympiad; the firſt year commencing with the neareſt new moon to the ſummer ſolſtice.

The firſt Olympiad began the 3938 year of the Julian period, the 3208 of the creation, 776 years before the birth of Chriſt, and 24 years before the foundation of Rome. And the computation by theſe, ended with the 404th Olympiad, being the 440th year of the preſent vulgar Chriſtian era.

OMBROMETER, a name given by Mr. Roger Pickering (Philoſ. Tranſ. No. 473, or Abridg. V, 456) to what is more commonly, though leſs properly, called a Pluviameter or Rain gage. See PLUVIAMETER.

OMPHALOPTER, or OMPHALOPTIC, in Optics, a glaſs that is convex on both ſides, popularly called a Convex Lens.

OPACITY, a quality of bodies which renders them opake, or the contrary of tranſparency.

The Carteſians make opacity to conſiſt in this; that the pores of the body are not all ſtraight, or directly before each other; or rather not pervious every way.

This doctrine however is deficient: for though, to have a body tranſparent, its pores muſt be ſtraight, or rather open every way; yet it is inconceivable how it ſhould happen, that not only glaſs and diamonds, but even water, whoſe parts are ſo very moveable, ſhould have all their pores open and pervious every way; while the fineſt paper, or the thinneſt gold leaf, ſhould exclude the light, for want of ſuch pores. So that another cauſe of Opacity muſt be ſought for.

Now all bodies have vaſtly more pores or vacuities than are neceſſary for an infinite number of rays to paſs freely through them in right lines, without ſtriking on any of the parts themſelves. For ſince water is 19 times lighter or rarer than gold; and yet gold itſelf is ſo very rare, that magnetic effluvia paſs freely through it, without any oppoſition; and quickſilver is readily received within its pores, and even water itſelf by compreſſion; it muſt have much more pores than ſolid parts: conſequently water muſt have at leaſt 40 times as much vacuity as ſolidity.

The cauſe therefore, why ſome bodies are opake, does not conſiſt in the want of rectilinear pores, pervious every way; but either in the unequal denſity of the parts, or in the magnitude of the pores; and to their being either empty, or filled with a different matter; by means of which, the rays of light, in their paſſage,

ſage, are arreſted by innumerable refractions and reflections, till at length falling on ſome ſolid part, they become quite extinct, and are utterly abſorbed.

Hence cork, paper, wood, &c, are opake; while glaſs, diamonds, &c, are pellucid. For in the confines or joining of parts alike in denſity, ſuch as thoſe of glaſs, water, diamonds, &c, among themſelves, no refraction or reflection takes place, becauſe of the equal attraction every way; ſo that ſuch of the rays of light as enter the firſt ſurface, paſs ſtraight through the body, excepting ſuch as are loſt and abſorbed, by ſtriking on ſolid parts: but in the bordering of parts of unequal denſity, ſuch as thoſe of wood and paper, both with regard to themſelves, and with regard to the air or empty ſpace in their larger pores, the attraction being unequal, the reflections and refractions will be very great; and thus the rays will not be able to paſs through ſuch bodies, being continually driven about, till they become extinct.

That this interruption or diſcontinuity of parts is the chief cauſe of Opacity, Sir Iſaac Newton argues, appears from hence; that all opake bodies immediately begin to be tranſparent, when their pores become filled with a ſubſtance of nearly equal denſity with their parts. Thus, paper dipped in water or oil, ſome ſtones ſteeped in water, linen cloth dipped in oil or vinegar, &c, become more tranſparent than before.

OPAKE, not tranſlucent, nor tranſparent, or not admitting a free paſſage to the rays of light.

OPEN *Flank*, in Fortification, is that part of the flank which is covered by the orillon or ſhoulder.

OPENING *of the Trenches*, is the firſt breaking of ground by the beſiegers, in order to carry on their approaches towards a place.

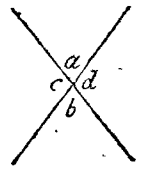
Opening *of Gates*, in Aſtrology, is when one planet ſeparates from another, and preſently applies to a third, bearing rule in a ſign oppoſite to that ruled by the planet with which it was before joined.

OPERA-*Glaſs*, in Optics, is ſo called from its uſe in play-houſes, and ſometimes a *Diagonal Perſpective*, from its conſtruction, which is as follows. ABCD (fig. 5, pl. xvii) repreſents a tube about 4 inches long; in each ſide of which there is a hole EF and GH, exactly againſt the middle of a plane mirror IK, which reflects the rays falling upon it to the convex glaſs LM; through which they are refracted to the concave eye-glaſs NO, whence they emerge parallel to the eye at the hole *rs*, in the end of the tube. Let P*a*Q be an object to be viewed, from which proceed the rays P*c*, *ab*, and Q*d*: theſe rays, being reflected by the plane mirror IK, will ſhew the object in the direction *cp*, *ba*, *dq*, in the image *pq*, equal to the object PQ, and as far behind the mirror as the object is before it: the mirror being placed ſo as to make an angle of 45 degrees with the ſides of the tube. And as, in viewing near objects, it is not neceſſary to magnify them, the focal diſtances of both the glaſſes may be nearly equal; or if that of LM be 3 inches, and that of NO one inch, the diſtance between them will be but 2 inches, and the object will be magnified 3 times, being ſufficient for the purpoſes to which this glaſs is applied.

When the object is very near, as XY, it is viewed through a hole *xy*, at the other end of the tube AB, without an eye glaſs; the upper part of the mirror being poliſhed for that purpoſe, as well as the under. The tube unſcrews near the object-glaſs LM, for taking out and cleanſing the glaſſes and mirror. The poſition of the object will be erect through the concave eye-glaſs.

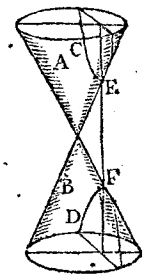
The peculiar artifice of this glaſs is to view a perſon at a ſmall diſtance, ſo that no one ſhall know who is obſerved; for the inſtrument points to a different object from that which is viewed; and as there is a hole on each ſide, it is impoſſible to know on which hand the object is ſituated, which you are viewing.

OPHIUCUS, a conſtellation of the northern hemiſphere; called alſo Serpentarius.



OPPOSITE *Angles*, or Vertical Angles, are thoſe oppoſite to each other, made by two interſecting lines; as *a* and *b*, or *c* and *d*.—The oppoſite angles are equal to each other.

Opposite *Cones*, denote two ſimilar cones vertically oppoſite, having the ſame common vertex and axis, and the ſame ſides produced; as the cones A and B.



Opposite *Sections*, or *Hyperbolas*, are thoſe made by cutting the Oppoſite cones by the ſame plane; as the hyperbolas C and D.—Theſe are always equal and ſimilar, and have the ſame tranſverſe axis EF, as alſo the ſame conjugate axis.

OPPOSITION, is that aſpect or ſituation of two planets or ſtars, when they are diametrically oppoſite to each other; being 180°, or a ſemi-circle apart; and marked thus ☍.

The moon is in Oppoſition to the ſun when ſhe is at the full.

OPTIC, or Optical, ſomething that relates to viſion, or the ſenſe of ſeeing, or the ſcience of optics.

Optic *Angle*. See Angle.

Optic *Axis*. See Axis.

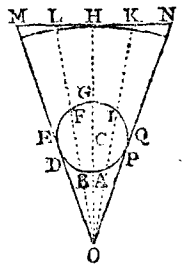
Optic *Chamber*. See Camera *Obſcura*.

Optic *Glaſſes*, are glaſſes ground either concave or convex; ſo as either to collect or diſperſe the rays of light; by which means viſion is improved, and the eye ſtrengthened, preſerved, &c.

Among theſe, the principal are ſpectacles, reading glaſſes, teleſcopes, microſcopes, magic lanterns, &c.

Optic *Inequality*, in Aſtronomy, is an apparent irregularity in the motions of far diſtant bodies; ſo called, becauſe it is not really in the moving bodies, but ariſing from the ſituation of the obſerver's eye. For if the eye were in the centre, it would always ſee the motions as they really are.

The



The Optic Inequality may be thus illuſtrated. Suppoſe a body revolving with a real uniform motion, in the periphery of a circle ABD &c; and ſuppoſe the eye in the plane of the ſame circle, but at a diſtance from it, viewing the motion of the body from O. Now when the body goes from A to B; its apparent motion is meaſured by the angle AOB or the arch or line HL, which it will ſeem to deſcribe. But while it moves through the arch BD in an equal time, its apparent motion will be determined by the angle BOD, or the arch or line LM, which is leſs than the former LH. But it ſpends the ſame time in deſcribing DE, as it does in AB or BD; during all which time of deſcribing DE it appears ſtationary in the point M. When it really deſcribes EFGIQ, it will appear to paſs over MLHKN; ſo that it will ſeem to have gone retrograde. And laſtly, from Q to P it will again appear ſtationary in the point N.

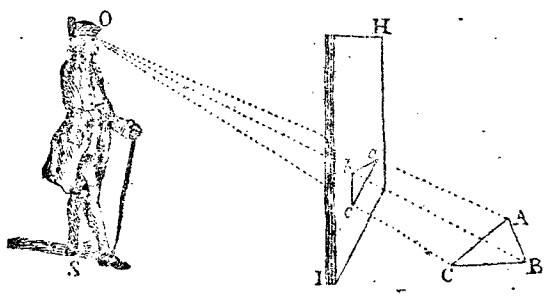
Optic *Nerves*, the ſecond pair of nerves, ſpringing from the crura of the medulla oblongata, and paſſing thence to the eye.

Theſe are covered with two coats, which they take from the dura and pia mater; and which, by their expanſions, form the two membranes of the eye, called the uvea and cornea. And the retina, which is a third membrane, and the immediate organ of ſight, is only an expanſion of the fibrous, or inner, and medullary part of theſe nerves.

Optic *Pencil*. See Pencil *of Rays*.

Optic *Place*, of a ſtar &c, is that point or part of its orbit, which is determined by our ſight, when the ſtar is ſeen there. This is either true or apparent; true, when the obſerver's eye is ſuppoſed to be at the centre of the motion; or apparent, when his eye is at the circumference of the earth. See alſo Place.

Optic *Pyramid*, in Perſpective, is the pyramid ABCO, whoſe baſe is the viſible object ABC, and the vertex is in the eye at O; being formed by rays



drawn from the ſeveral points of the perimeter to the eye.

Hence alſo may appear what is meant by Optic triangle.

Optic *Rays*, particularly means thoſe by which an Optic pyramid, or Optic triangle, is terminated. As OA, OB, OC, &c.

OPTICS, the ſcience of viſion; including Catoptrics, and Dioptrics; and even Perſpective; as alſo the whole doctrine of light and colours, and all the phenomena of viſible objects.

Optics, in its more extenſive acceptation, is a mixed mathematical ſcience; which explains the manner in which viſion is performed in the eye; treats of ſight in general; gives the reaſons of the ſeveral modifications or alterations, which the rays of light undergo in the eye; and ſhews why objects appear ſometimes greater, ſometimes ſmaller, ſometimes more diſtinct, ſometimes more confuſed, ſometimes nearer and ſometimes more remote. In this extenſive ſignification it is conſidered by Newton, in his excellent work called Optics.

Indeed Optics makes a conſiderable branch of natural philoſophy; both as it explains the laws of nature, according to which viſion is performed, and as it accounts for abundance of phyſical phenomena, otherwiſe inexplicable.

The Principal Authors and Diſcoveries in Optics, are the following:

Euclid ſeems to be the earlieſt author on Optics that we have. He compoſed a treatiſe on the ancient Optics and catoptrics; dioptrics being leſs known to the Ancients; though it was not quite unnoticed by them, for among the phenomena, at the beginning of that work, Euclid remarks the effect of bringing an object into view, by refraction, in the bottom of a veſſel, by pouring water into it, which could not be ſeen over the edge of the veſſel, before the water was poured in; and other authors ſpeak of the then known effects of glaſs globes &c, both as burning glaſſes, and as to bodies ſeen through them. Euclid's work however is chiefly on catoptrics, or reflected rays; in which he ſhews, in 31 propoſitions, the chief properties of them, both in plane, convex, and concave ſurfaces, in his uſual geometrical manner; beginning with that concerning the equality of the angles of incidence and reflection, which he demonſtrates; and in the laſt propoſition, ſhewing the effect of a concave ſpeculum, as a burning glaſs, when expoſed to the rays of the ſun.

The effects of burning glaſſes, both by refraction and reflection, are noticed by ſeveral others of the Ancients, and it is probable that the Romans had a method of lighting their ſacred fire by ſome ſuch means. Ariſtophanes, in one of his comedies, introduces a perſon as making uſe of a globe filled with water to cancel a bond that was againſt him, by thus melting the wax of the ſeal. And if we give but a ſmall degree of credit to what ſome ancient hiſtorians are ſaid to have written concerning the exploits of Archimedes, we ſhall be induced to think that he conſtructed ſome very powerful burning mirrors. It is even allowed that this eminent geometrician wrote a treatiſe on the ſubject of them, though it be not now extant; as alſo concerning the appearance of a ring or circle under water, and therefore could not have been ignorant of the common phenomena of refraction. We find many queſtions concerning ſuch optical appearances in Ariſtotle. This author was alſo ſenſible that it is the reflection of light from the atmoſphere which prevents total darkneſs after the ſun ſets, and in places where he does not ſhine in the day time. He was alſo of opinion, that rainbows, halos,

halos, and mock suns, were all occasioned by the reflection of the sunbeams in different circumstances, by which an imperfect image of his body was produced, the colour only being exhibited, and not his proper figure.

The Ancients were not only acquainted with the more ordinary appearances of refraction, but knew also the production of colours by refracted light. Seneca says, that when the light of the sun shines through an angular piece of glass, it shews all the colours of the rainbow. These colours however, he says, are false, such as are seen in a pigeon's neck when it changes its position; and of the same nature he says is a speculum, which, without having any colour of its own, assumes that of any other body.

It appears also, that the Ancients were not unacquainted with the magnifying power of glass globes filled with water, though it does not appear that they knew any thing of the reason of this power: and it is supposed that the ancient engravers made use of a glass globe filled with water to magnify their figures, that they might work to more advantage.

Ptolomy, about the middle of the second century, wrote a considerable treatise on Optics. The work is lost; but from the accounts of others, it appears that he there treated of astronomical refractions. The first astronomers were not aware that the intervals between stars appear less when near the horizon than in the meridian; and on this account they must have been much embarrassed in their observations: but it is evident that Ptolomy was aware of this circumstance by the caution which he gives to allow something for it, whenever recourse is had to ancient observations. This philosopher also advances a very sensible hypothesis to account for the remarkably great apparent size of the sun and moon when seen near the horizon. The mind, he says, judges of the size of objects by means of a preconceived idea of their distance from us: and this distance is fancied to be greater when a number of objects are interposed between the eye and the body we are viewing; which is the case when we see the heavenly bodies near the horizon. In his Almagest, however, he ascribes this appearance to a refraction of the rays by vapours, which actually enlarge the angle under which the luminaries appear; just as the angle is enlarged by which an object is seen from under water.

Alhazen, an Arabian writer, was the next author of consequence, who wrote about the year 1100. Alhazen made many experiments on refraction, at the surface between air and water, air and glass, and water and glass; and hence he deduced several properties of atmospherical refraction; such as, that it increases the altitudes of all objects in the heavens; and he first advanced that the stars are sometimes seen above the horizon by means of refraction, when they are really below it: which observation was confirmed by Vitello, Walther, and especially by the observations of Tycho Brahe. Alhazen observed, that refraction contracts the diameters and distances of the heavenly bodies, and that it is the cause of the twinkling of the stars. This refractive power he ascribed, not to the vapours contained in the air, but to its different degrees of transparency. And it was his opinion, that so far from being the cause of the heavenly bodies appearing larger near the horizon, that it would make them appear less; observing that two stars appear nearer together in the horizon, than near the meridian. This phenomenon he ranks among optical deceptions. We judge of distance, he says, by comparing the angle under which objects appear, with their supposed distance; so that if these angles be nearly equal, and the distance of one object be conceived greater than that of the other, this will be imagined to be the larger. And he farther observes, that the sky near the horizon is always imagined to be farther from us than any other part of the concave surface.

In the writings of Alhazen too, we find the first distinct account of the magnifying power of glasses; and it is not improbable that his writings on this head gave rise to the useful invention of spectacles: for he says, that if an object be applied close to the base of the larger segment of a sphere of glass, it will appear magnified. He also treats of the appearance of an object through a globe, and says that he was the first who observed the refraction of rays into it.

In 1270, Vitello, a native of Poland, published a treatise on Optics, containing all that was valuable in Alhazen, and digested in a better manner. He observes, that light is always lost by refraction, which makes objects appear less luminous. He gave a table of the results of his experiments on the refractive powers of air, water, and glass, corresponding to different angles of incidence. He ascribes the twinkling of the stars to the motion of the air in which the light is refracted; and he illustrates this hypothesis, by observing that they twinkle still more when viewed in water put in motion. He also shews, that refraction is necessary as well as reflection, to form the rainbow; because the body which the rays fall upon is a transparent substance, at the surface of which one part of the light is always reflected, and another refracted. And he makes some ingenious attempts to explain refraction, or to ascertain the law of it. He also considers the foci of glass spheres, and the apparent size of objects seen through them; though with but little accuracy.

To Vitello may be traced the idea of seeing images in the air. He endeavours to shew, that it is possible, by means of a cylindrical convex speculum, to see the images of objects in the air, out of the speculum, when the objects themselves cannot be seen.

The Optics of Alhazen and Vitello were published at Basil in 1572, by Fred. Risner.

Contemporary with Vitello, was Roger Bacon, a man of very extensive genius, who wrote upon almost every branch of science; though it is thought his improvements in Optics were not carried far beyond those of Alhazen and Vitello. He even assents to the absurd notion, held by all philosophers down to his time, that visible rays proceed *from* the eye, instead of *towards* it. From many stories related of him however, it would seem, that he made greater improvements than appear in his writings. It is said he had the use of spectacles: that he had contrivances, by reflection from glasses, to see what was doing at a great distance, as in an enemy's camp. And lord chancellor Bacon relates a story, of his having apparently walked in the air between two steeples, and which he supposed was effected by

by reflection from glaſſes while he walked upon the ground.

About 1279 was written a treatiſe on Optics by Peccam, archbiſhop of Canterbury.

One of the next who diſtinguiſhed himſelf in this way, was Maurolycus, teacher of mathematics at Meſſina. In a treatiſe, De Lumine et Umbra, publiſhed in 1575, he demonſtrates, that the cryſtalline humour of the eye is a lens that collects the rays of light iſſuing from the objects, and throws them upon the retina, where the focus of each pencil is. From this principle he diſcovered the reaſon why ſome people are ſhort-ſighted, and others long-ſighted; alſo why the former are relieved by concave glaſſes, and the others by convex ones.

Contemporary with Maurolycus, was John Baptiſta Porta, of Naples. He diſcovered the Camera Obſcura, which throws conſiderable light on the nature of viſion. His houſe was the conſtant reſort of all the ingenious perſons at Naples, whom he formed into what he called An Academy of Secrets; each member being obliged to contribute ſomething that was not generally known, and might be uſeful. By this means he was furniſhed with materials for his Magia Naturalis, which contains his account of the Camera Obſcura, and the firſt edition of which was publiſhed, as he informs us, when he was not quite 15 years old. He alſo gave the firſt hint of the Magic Lantern; which Kircher afterwards followed and improved. His experiments with the camera obſcura convinced him, that viſion is performed by the intromiſſion of ſomething into the eye, and not by viſual rays proceeding from it, as had been formerly imagined; and he was the firſt who fully ſatisfied himſelf and others upon this ſubject. He juſtly conſidered the eye as a camera obſcura, and the pupil the hole in the window-ſhutter; but he was miſtaken in ſuppoſing that the cryſtalline humour correſponds to the wall which receives the images; nor was it diſcovered till the year 1604, that this office is performed by the retina. He made a variety of juſt remarks concerning viſion; and particularly explained ſeveral caſes in which we imagine things to be without the eye, when the appearances are occaſioned by ſome affection of the eye itſelf, or by ſome motion within the eye. —He remarked alſo that, in certain circumſtances, viſion will be aſſiſted by convex or concave glaſſes; and he ſeems even to have made ſome ſmall advances towards the diſcovery of teleſcopes.

Other treatiſes on Optics, with various and gradual improvements, were afterwards ſucceſſively publiſhed by ſeveral authors: as Aguilon, Opticorum libr. 6, Antv. 1613; L'Optique, Catoptrique, & Dioptrique of Herigone, in his Curſus Math. Paris 1637; the Dioptries of Des Cartes, 1637; L'Optique & Catoptrique of Merſenne, Paris 1651: Scheiner, Optica, Lond. 1652: Mañchini, Dioptrica Practica, Bologna, 1660: Barrow, Lectiones Opticæ, London 1663: James Gregory, Optica Promota, Lond. 1663: Grimaldi, Phyſico-matheſis de Lumine, Coloribus, & Iride, Bononia, 1665: Scaphuſa, Cogitationes Phyſico-mechanicæ de Natura Viſionis, Heidel. 1670: Kircher, Ars Magna Lucis & Umbræ, Rome 1671: Cherubin, Dioptrique Oculaire, Paris 1671: Leibnitz, Principe Generale de l'Optique, Leipſic Acts 1682: Newton's Optics and Lectiones Opticæ, 4to and 8vo, 1704 &c: Molyneux, Dioptrics, Lond. 1692: Dr. Jurin's Theory of Diſtinct and Indiſtinct Viſion.—There is alſo a large and excellent work on Optics, by Dr. Smith, 2 vols 4to; and an elaborate Hiſtory of the Preſent State of Diſcoveries relating to Viſion, Light, and Colours, by Dr. Prieſtley, 4to, 1772; with a multitude of other authors of inferior note; beſides leſſer and occaſional tracts and papers in the Memoirs of the ſeveral learned Academies and Societies of Europe; with improvements by many other perſons, among whom are the reſpectable names of Sneil, Fermat, Kepler, Huygens, Hortenſius, Boyle, Hook, De la Hire, Lowthorp, Caſſini, Halley, Deliſle, Euler, Dollond, Clairaut, D'Alembert, Zeiher, Bouguer, Buffon, Nollet, Baume; but the particular improvements by each author muſt be referred to the hiſtory of his life, under the article of their names; while the hiſtory and improvements of the ſeveral branches are to be found under the various particular articles, as, Light, Colours, Reflection, Refraction, Inflection, Tranſmiſſion, &c, Spectacles, Teleſcope, Microſcope, &c, &c.

ORB, a ſpherical ſhell, hollow ſphere, or ſpace contained between two concentric ſpherical ſurfaces.—The ancient aſtronomers conceived the heavens as conſiſting of ſeveral vaſt azure tranſparent Orbs or ſpheres, incloſing one another, and including the bodies of the planets.

The Orbis *Magnus*, or *Great* Orb, is that in which the ſun is ſuppoſed to revolve; or rather it is that in which the earth makes its annual circuit.

Orb, in Aſtrology, or Orb *of Light*, is a certain ſphere or extent of light, which the aſtrologers allow a planet beyond its centre. They pretend that, provided the aſpects do but fall within this Orb, they have almoſt the ſame effect as if they pointed directly againſt the centre of the planet.—The Orb of Saturn's light they make to be 10 degrees; that of Jupiter 12 degrees; that of Mars $7\frac{1}{2}$; that of the Sun 17 degrees; that of Venus 8 degrees; that of Mercury 7 degrees; and that of the Moon $12\frac{1}{2}$ degrees.

ORBIT, is the path of a planet or comet; being the curve line deſcribed by its centre, in its proper motion in the heavens. So the earth's Orbit, is the ecliptic, or the curve it deſcribes in its annual revolution about the ſun.

The ancient aſtronomers made the planets deſcribe circular Orbits, with an uniform velocity. Copernicus himſelf could not believe they ſhould do otherwiſe; being unable to diſentangle himſelf entirely from the excentrics and epicycles to which they had recourſe, to account for the inequalities in their motions.

But Kepler found, from obſervations, that the Orbit of the earth, and that of every primary planet, is an ellipſis, having the ſun in one of its foci; and that they all move in theſe ellipſes by this law, that a radius drawn from the centre of the ſun to the centre of the planet, always deſcribes equal areas in equal times; or, which is the ſame thing, in unequal times, it deſcribes areas that are proportional to thoſe times. And Newton has ſince demonſtrated, from the nature of univerſal gravitation, and projectile motion, that the Orbits muſt of neceſſity be ellipſes, and the motions obſerve that law,

law, both of the primary and ſecondary planets; excepting in ſo far as their motions and paths are diſturbed by their mutual actions upon one another; as the Orbit of the earth by that of the moon; or that of Saturn by the action of Jupiter; &c.

Of theſe elliptic Orbits, there have been two kinds aſſigned: the firſt that of Kepler and Newton, which is the common or conical ellipſe; for which Seth Ward, though he himſelf keeps to it, thinks we might venture to ſubſtitute circular Orbits, by uſing two points, taken at equal diſtances from the centre, on one of the diameters, as is done in the foci of the ellipſis, and which is called his Circular Hypotheſis. The ſecond is that of Caſſini, of this nature, viz, that the products of the two lines drawn from the two foci, to any point in the circumference, are everywhere equal to the ſame conſtant quantity; whereas, in the common ellipſe, it is the ſum of thoſe two lines that is always a conſtant quantity.

The Orbits of the planets are not all in the ſame plane with the ecliptic, which is the earth's Orbit round the ſun, but are variouſly inclined to it, and to each other: but ſtill the plane of the ecliptic, or earth's Orbit, interſects the plane of the Orbit of every other planet, in a right line which paſſes through the ſun, called the line of the nodes, and the points of interſection of the Orbits themſelves are called the nodes.

The mean ſemidiameters of the ſeveral Orbits, or the mean diſtances of the planets from the ſun, with the excentricities of the Orbits, their inclination to the ecliptic, and the places of their nodes, are as in the following table; where the 2d column contains the proportions of ſemidiameters of the Orbits, the true ſemidiameter of that of the earth being 95 millions of miles; and the 3d column ſhews what part of the ſemidiameters the excentricities are equal to.

	Propor. ſemid.	Excentr. pts. of ſemidiam.	Inclina. of Orbit.	Aſcending Node, 1790.
Mercury	387	$\frac{1}{5}$	6° 54′	♉ 14° 43
Venus	723	$\frac{1}{138}$	3 20	♊ 13 59
Earth	1000	$\frac{1}{39}$	0 0	- -
Mars	1524	$\frac{1}{11}$	1 52	♉ 17 17
Jupiter	5201	$\frac{1}{21}$	1 20	♋ 7 29
Saturn	9539	$\frac{1}{18}$	2 30	♋ 21 13
Georgian	19634	$\frac{1}{17}$	0 48	♊ 12 54

The Orbits of the comets are alſo very excentric ellipſes.

ORDER, in Architecture, a ſyſtem of the ſeveral members, ornaments, and proportions of a column and pilaſter.

There are five Orders of columns, of which three are Greek, viz, the Doric, Ionic, and Corinthian; and two Italic, viz, the Tuſcan and Compoſite. The three Greek Orders repreſent the three different manners of building, viz, the ſolid, the delicate, and the middling: the two Italic ones are imperfect productions of theſe.

ORDER, in Aſtronomy. A planet is ſaid to go according to the order of the ſigns, when it is direct; proceeding from Aries to Taurus, thence to Gemini, &c. As, on the contrary, it goes contrary to the Order of the ſigns, when it is retrograde, or goes backward, from Piſces to Aquarius, &c.

ORDER, in the Geometry of Curve Lines, is denominated from the rank or Order of the equation by which the geometrical line is expreſſed; ſo the ſimple equation, or 1ſt power, denotes the 1ſt Order of lines, which is the right line; the quadratic equation, or 2d power, defines the 2d Order of lines, which are the conic ſections and circle; the cubic equation, or 3d power, defines the 3d Order of lines; and ſo on.

Or, the Orders of lines are denominated from the number of points in which they may be cut by a right line. Thus, the right line is of the 1ſt Order, becauſe it can be cut only in one point by a right line; the circle and conic ſections are of the 2d Order, becauſe they can be cut in two points by a right line; while thoſe of the 3d Order, are ſuch as can be cut in 3 points by a right line; and ſo on.

It is to be obſerved, that the Order of curves is always one degree lower than the correſponding line; becauſe the 1ſt Order, or right line, is no curve; and the circle and conic ſections, which are the 2d Order of lines, are only the 1ſt Order of curves; &c.

See Newton's Enumeratio Linearum Tertii Ordinis.

ORDINATES, in the Geometry of Curve Lines, are right lines drawn parallel to each other, and cutting the curve in a certain number of points.

The parallel Ordinates are uſually all cut by ſome other line, which is called the abſciſs, and commonly the Ordinates are perpendicular to the abſciſſal line. When this line is a diameter of the curve, the property of the Ordinates is then the moſt remarkable; for, in the curves of the firſt kind, or the conic ſections and circle, the Ordinates are all biſected by the diameter, making the part on one ſide of it equal to the part on the other ſide of it; and in the curves of the 2d order, which may be cut in three points by an Ordinate, then of the three parts of the Ordinate, lying between theſe three interſections of the curve and the interſection with the diameter, the part on one ſide the diameter is equal to both the two parts on the other ſide of it. And ſo for curves of any order, whatever the number of interſections may be, the ſum of the parts of any Ordinate, on one ſide of the diameter, is equal to the ſum of the parts on the other ſide of it.

The uſe of Ordinates in a curve, and their abſciſſes, is to define or expreſs the nature of a curve, by means of the general relation or equation between them; and the greateſt number of factors, or the dimenſions of the higheſt term, in ſuch equation, is always the ſame as the order of the line; that equation being a quadratic, or its higheſt term of two dimenſions, in the lines of the 2d order, being the circle and conic ſections; and a cubic equation, or its higheſt term containing 3 dimenſions, in the lines of the 3d order; and ſo on.

Thus,

Thus, y denoting an Ordinate BC, and x its abſciſs AB; alſo a, b, c, &c, given quantities: then $y^2 = ax^2 + bx + c$ is the general equation for the lines of the 2d order; and $xy^2 - ey = ax^3 + bx^2 + cx + d$ is the equation for the lines of the 3d order; and ſo on.

ORDNANCE, are all ſorts of great guns, uſed in war; ſuch as cannon, mortars, howitzers, &c.

ORFFYREUS's *Wheel*, in Mechanics, is a machine ſo called from its inventor, which he aſſerted to be a perpetual motion. This machine, according to the account given of it by Graveſande, in his Oeuvres Philoſophiques, publiſhed by Allemand, Amſt. 1774, conſiſted externally of a large circular wheel, or rather drum, 12 feet in diameter, and 14 inches deep; being very light, as it was formed of an aſſemblage of deals, having the intervals between them covered with waxed cloth, to conceal the interior parts of it. The two extremities of an iron axis, on which it turned, reſted on two ſupports. On giving a ſlight impulſe to the wheel, in either direction, its motion was gradually accelerated; ſo that after two or three revolutions it acquired ſo great a velocity as to make 25 or 26 turns in a minute. This rapid motion it actually preſerved during the ſpace of 2 months, in a chamber of the landgrave of Heſſe, the door of which was kept locked, and ſealed with the landgrave's own ſeal. At the end of that time it was ſtopped, to prevent the wear of the materials. The profeſſor, who had been an eye-witneſs to theſe circumſtances, examined all the external parts of it, and was convinced that there could not be any communication between it and any neighbouring room. Orffyreus however was ſo incenſed, or pretended to be ſo, that he broke the machine in pieces, and wrote on the wall, that it was the impertinent curioſity of profeſſor Graveſande which made him take this ſtep. The prince of Heſſe, who had ſeen the interior parts of this wheel, but ſworn to ſecreſy, being aſked by Graveſande, whether, after it had been in motion for ſome time, there was any change obſervable in it, and whether it contained any pieces that indicated fraud or deception, anſwered both queſtions in the negative, and declared that the machine was of a very ſimple conſtruction.

ORGANICAL *Deſcription of Curves*, is the deſcription of them upon a plane, by means of inſtruments, and commonly by a continued motion. The moſt ſimple conſtruction of this kind, is that of a circle by means of a pair of compaſſes. The next is that of an ellipſe by means of a thread and two pins in the foci, or the ellipſe and hyperbola, by means of the elliptical and hyperbolic compaſſes.

A great variety of deſcriptions of this ſort are to be found in Schooten De Organica Conic. Sect. in Plano Deſcriptione; in Newton's Arithmetica Univerſalis, De Curvarum Deſcriptione Organica; Maclaurin's Geometria Organica; Brackenridge's Deſcriptio Linearum Curvarum; &c.

ORGUES, or ORGANS, in Fortification, long and thick pieces of wood, ſhod with pointed iron, and hung each by a ſeparate rope over the gate-way of a town, ready on any ſurpriſe or attempt of the enemy to be let down to ſtop up the gate. The ends of the ſeveral ropes are wound about a windlaſs, ſo as to be let down all together.

ORGUES is alſo uſed for a machine compoſed of ſeveral harquebuſſes or muſket-barrels, bound together; ſo as to make ſeveral exploſions at the ſame time. They are uſed to defend breaches and other places attacked.

ORIENT, the eaſt, or the eaſtern point of the horizon.

ORIENT *Equinoctial*, is uſed for that point of the horizon where the ſun riſes when he is in the equinoctial, or when he enters the ſigns Aries and Libra.

ORIENT *Aeſtival*, is the point where the ſun riſes in the middle of ſummer, when the days are longeſt.

ORIENT *Hibernal*, is the point where the ſun riſes in the middle of winter, when the days are ſhorteſt.

ORIENTAL, ſituated towards the eaſt with regard to us: in oppoſition to occidental or the weſt.

ORIENTAL *Aſtronomy*, *Philoſophy*, &c. uſed for thoſe of the eaſt, or of the Arabians, Chaldeans, Perſians, Indians, &c.

ORILLON, in Fortification, a ſmall rounding of earth, lined with a wall, raiſed on the ſhoulder of thoſe baſtions that have caſemates, to cover the cannon in the retired flank, and prevent their being dismounted by the enemy.

There are other ſorts of Orillons, properly called Epaulements, or Shoulderings, which are almoſt of a ſquare figure.

ORION, a conſtellation of the ſouthern hemiſphere, with reſpect to the ecliptic, but half in the northern, and half on the ſouthern ſide of the equinoctial, which runs acroſs the middle of his body.

The ſtars in this conſtellation are, 38 in Ptolomy's catalogue, 42 in Tycho's, 62 in Hevelius's, and 78 in Flamſteed's. But ſome teleſcopes have diſcovered ſeveral thouſands of ſtars in this conſtellation.

Of theſe ſtars, there are no leſs than two of the firſt magnitude, and four of the ſecond, beſide a great many of the third and fourth. One of thoſe two ſtars of the firſt magnitude is upon the middle of the left foot, and is called *Regel*; the other is on the right ſhoulder, and called *Betelgueſe*; of the four of the ſecond magnitude, one is on the left ſhoulder, and called *Bellatrix*, and the other three are in the belt, lying nearly in a right line and at equal diſtances from each other, forming what is popularly called the *Yardwand*.

This conſtellation is one of the 48 old aſteriſms, and one of the moſt remarkable in the heavens. It is in the figure of a man, having a ſword by his ſide, and ſeems attacking the bull with a club in his right hand, his left bearing a ſhield.

This conſtellation is particularly mentioned by many of the ancient authors, and even in the Scriptures themſelves. The Greeks, according to their cuſtom, give ſeveral fabulous accounts of him. One is, that this Orion was a ſon of their ſea-god Neptune by Euryale, the famous huntreſs. The ſon poſſeſſed the diſpoſition of his mother, and became the greateſt hunter in the world: and Neptune gave him the ſingular privilege, that he ſhould walk upon the ſurface of the ſea as well

as if it were on dry land. Another account of his origin is, that one Hyreius in Thebes, having entertained Jupiter and Mercury with great hoſpitality, requeſted of them the favour that he might have a ſon. The ſkin of the ox which he had ſacrificed to them, was buried in the ground, with certain ceremonies, and the ſon ſo much deſired was produced from it, a youth of promiſing ſpirit, and named Orion.

They farther tell us, that he viſited Chios when grown up, and raviſhed Penelope the daughter of Œnopion, for which the father put out his eyes, and baniſhed him the iſland: he thence went to Lemnos, where Vulcan received him, and gave him Cedalion for a companion. Afterwards, being reſtored to ſight by the ſun, he returned to Chios, and would have revenged himſelf on the king, but the people hid him. After this it ſeems he hunted with Diana, and was ſo exalted with his ſucceſs, that he uſed to ſay he would deſtroy every creature on the earth: the Earth, irritated at this, produced a Scorpion, which ſtung him to death, and both he and the reptile were taken up to the ſkies, the Scorpion making one of the twelve ſigns of the zodiac.

Others give a different account of his deſtruction: they tell us that he would have raviſhed the goddeſs of chaſtity Diana herſelf, and that ſhe killed him with her arrow. All the writers, however, are not agreed about this: they who make him the ſacrifice to the vengeance of the offended goddeſs, ſay, that herſelf afterwards placed his figure in the ſkies as a memorial of the attempt, and a terror to all ages. But there are ſome who ſay ſhe loved him ſo well that ſhe had thoughts of marrying him: theſe add, that Apollo could not bear ſo diſhonourable an alliance for his ſiſter, for which reaſon he killed him; and that Diana, after ſhedding ſhowers of tears over his corps, obtained of Jupiter a place for him in the heavens.

No conſtellation was ſo terrible to the mariners of the early periods, as this of Orion. He is mentioned in this way by all the Greek and Latin poets, and even by their hiſtorians; his riſing and ſetting being attended by ſtorms and tempeſts: and as the northern conſtellations are made the followers of the Pleiades; ſo are the ſouthern ones made the attendants of Orion.

The name of this conſtellation is alſo met with in Scripture ſeveral times, viz, in the books of Job, Amos, and Iſaiah. In Job it is aſked, "Canſt thou bind the ſweet influence of the Pleiades, or looſe the bands of Orion?" And Amos ſays, "Seek him that maketh the Seven Stars and Orion, and turneth the ſhadow of death into morning."

ORION's *River*, the ſame as the conſtellation Eridanus.

ORLE, ORLET, or ORLO, in Architecture, a fillet under the ovolo, or quarter-round of a capital.—When it is at the top or bottom of the ſhaft, it is called the cincture.—Palladio alſo uſes Orlo for the plinth of the baſes of columns and pedeſtals.

ORRERY, an aſtronomical machine, for exhibiting the various motions and appearances of the ſun and planets; and hence often called a Planetarium.

The reaſon of the name Orrery was this: Mr. Rowley, a mathematical inſtrument-maker, having got one from Mr. George Graham, the original inventor, to be ſent abroad with ſome of his own inſtruments, he copied it, and made the firſt for the earl of Orrery, Sir Richard Steel, who knew nothing of Mr. Graham's machine, thinking to do juſtice to the firſt encourager, as well as to the inventor of ſuch a curious inſtrument, called it an Orrery, and gave Rowley the praiſe due to Mr. Graham. Deſaguliers' Experim. Philoſ. vol. 1, pa. 430. The figure of this grand Orrery is exhibited at fig. 1, pl. 19. It is ſince made in various other figures.

ORTEIL, in Fortification. See BERME.

ORTELIUS (ABRAHAM), a celebrated geographer, was born at Antwerp, in 1527. He was well ſkilled in the languages and mathematics, and acquired ſuch reputation by his ſkill in geography, that he was ſurnamed the *Ptolomy of his time*. Juſtus Lipſius, and moſt of the great men of the 16th century, were our author's intimate friends. He paſſed ſome time at Oxford in the reign of Edward the 6th; and he viſited England a ſecond time in 1577.

His *Theatrum Orbis Terræ* was the completeſt work of the kind that had ever been publiſhed, and gained our author a reputation adequate to his immenſe labour in compiling it. He wrote alſo ſeveral other excellent geographical works; the principal of which are, his *Theſaurus*, and his *Synonyma Geographica*.—The world is alſo obliged to him for the *Britannia*, which was undertaken by Cambden at his requeſt.—He died at Antwerp, 1598, at 71 years of age.

ORTHODROMICS, in Navigation, is Great-circle ſailing, or the art of ſailing in the arch of a great circle, which is the ſhorteſt courſe: For the arch of a great circle is Orthodromia, or the ſhorteſt diſtance between two points or places.

ORTHOGONIAL, in Geometry, is the ſame as rectangular, or right-angled.—When the term refers to a plane figure, it ſuppoſes one leg or ſide to ſtand perpendicular to the other: when ſpoken of ſolids, it ſuppoſes their axis to be perpendicular to the plane of the horizon.

ORTHOGRAPHIC or ORTHOGRAPHICAL *Projection of the Sphere*, is the projection of its ſurface or of the ſphere on a plane, paſſing through the middle of it, by an eye vertically at an infinite diſtance. See PROJECTION.

ORTHOGRAPHY, in Geometry, is the drawing or delineating the fore-right plan or ſide of any object, and of expreſſing the heights or elevations of every part. Being ſo called from its determining things by perpendicular right lines falling on the geometrical plan; or rather, becauſe all the horizontal lines are here ſtraight and parallel, and not oblique as in repreſentations of perſpective.

ORTHOGRAPHY, in Architecture, is the profile or elevation of a building, ſhewing all the parts in their true proportion. This is either external or internal.

External ORTHOGRAPHY, is a delineation of the outer face or front of a building; ſhewing the principal wall with its apertures, roof, ornaments, and every thing viſible to an eye placed before the building. And

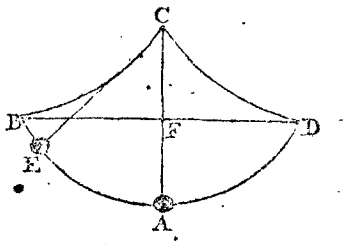
Internal ORTHOGRAPHY, called alſo a Section, is a delineation or draught of a building, ſuch as it would appear if the external wall were removed.

ORTHOGRAPHY, in Fortification, is the profile, or repreſentation

repreſentation of a work; or a draught ſo conducted, as that the length, breadth, height, and thickneſs of the ſeveral parts are expreſſed, ſuch as they would appear, if it were perpendicularly cut from top to bottom.

ORTIVE, or *Eaſtern Amplitude*, in Aſtronomy, is an arch of the horizon intercepted between the point where a ſtar riſes, and the eaſt point of the horizon.

OSCILLATION, in Mechanics, vibration, or the reciprocal aſcent and deſcent of a pendulum.



If a ſimple pendulum be ſuſpended between two ſemicycloids BC, CD, that have the diameter CF of the generating circle equal to half the length of the ſtring, ſo that the ſtring, as the body E Oſcillates, folds about them, then will the body Oſcillate in another cycloid BEAD, ſimilar and equal to the former. And the time of the Oſcillation in any arc AE, meaſured from the loweſt point A, is always the ſame conſtant quantity, whether that arc be larger or ſmaller. But the Oſcillations in a circle are unequal, thoſe in the ſmaller arcs being leſs than thoſe in the larger; and ſo always leſs and leſs as the arcs are ſmaller, but ſtill greater than the time of Oſcillation in a cycloidal arc; till the circular arc becomes very ſmall, and then the time of Oſcillation in it is very nearly equal to the time in the cycloid, becauſe the circle and cycloid have the ſame curvature at the vertex, the length of the ſtring being the common radius of curvature to them there.

The time of one whole Oſcillation in the cycloid, or of an aſcent and deſcent in any arch of it, is to the time in which a heavy body would fall freely through CF or FA, the diameter of the generating circle, or through half the length of the pendulum ſtring, as the circumference of a circle is to its diameter, that is as 3·1416 to 1. So that if l denote the length of the pendulum CA, and $g = 16\frac{1}{12}$ feet $= 193$ inches, the ſpace a heavy body falls in the 1ſt ſecond of time, and $p = 3{\cdot}1416$ the circumference of a circle whoſe diameter is 1; then by the laws of falling bodies,

it is $\sqrt{g} : \sqrt{\frac{1}{2}l} :: 1'' : \sqrt{\frac{l}{2g}}$, the time of falling through CF or $\frac{1}{2}l$; therefore $1 : p :: \sqrt{\frac{l}{2g}} : p\sqrt{\frac{l}{2g}}$, which is the time of one vibration in any arch of the cycloid which has the diameter of its generating circle equal to $\frac{1}{2}l$. Or, by extracting the known numbers, the ſame time of an Oſcillation becomes barely $\frac{6}{25}\sqrt{l}$ or $\frac{16}{100}\sqrt{l}$ very nearly, l being the length of the pendulum in inches. And therefore this is alſo very nearly the time of an Oſcillation in a ſmall circular arc, whoſe radius is l inches.

Hence the times of the Oſcillation of pendulums of different lengths, are directly in the ſubduplicate ratio of their lengths, or as the ſquare roots of their lengths.

The more exact time of Oſcillating in a circular arc, when this is of ſome finite ſmall length, is $\frac{4}{25}\sqrt{l} \times (1 + \frac{h}{8l})$; where h is the height of the vibration, or the verſed ſine of the ſingle arc of aſcent, or deſcent, to the radius l.

The celebrated Huygens firſt reſolved the problem concerning the Oſcillations of pendulums, in his book De Horologio Oſcillatorio, reducing compound pendulums to ſimple ones. And his doctrine is founded on this hypotheſis, that the common centre of gravity of ſeveral bodies, connected together, muſt aſcend exactly to the ſame height from which it fell, whether thoſe bodies be united, or ſeparated from one another in aſcending again, provided that each begin to aſcend with the velocity acquired by its deſcent.

This ſuppoſition was oppoſed by ſeveral, and very much ſuſpected by others. And thoſe even who believed the truth of it, yet thought it too daring to be admitted without proof into a ſcience which demonſtrates every thing.

At length Mr. James Bernoulli demonſtrated it, from the nature of the lever; and publiſhed his ſolution in the Mem. Acad. of Scienc. of Paris, for the year 1703. After his death, which happened in 1705, his brother John Bernoulli gave a more eaſy and ſimple ſolution of the ſame problem, in the ſame Memoirs for 1714; and about the ſame time, Dr. Brook Taylor publiſhed a ſimilar ſolution in his Methodus Incrementorum: which gave occaſion to a diſpute between theſe two mathematicians, who accuſed each other of having ſtolen their ſolutions. The particulars of which diſpute may be ſeen in the Leipſic Acts for 1716, and in Bernoulli's works, printed in 1743.

Axis of OSCILLATION, is a line parallel to the horizon, ſuppoſed to paſs through the centre or fixed point about which the pendulum oſcillates, and perpendicular to the plane in which the Oſcillation is made.

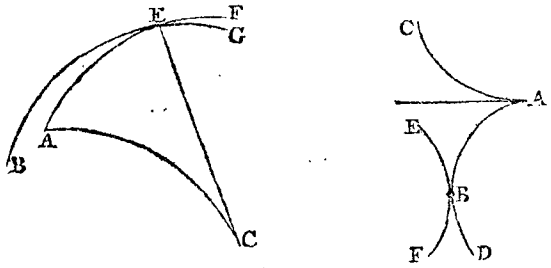
Centre of OSCILLATION, in a ſuſpended body, is a certain point in it, ſuch that the Oſcillations of the body will be made in the ſame time as if that point alone were ſuſpended at that diſtance from the point of ſuſpenſion. Or it is the point into which if the whole weight of the body be collected, the ſeveral Oſcillations will be performed in the ſame time as before: the Oſcillations being made only by the force of gravity of the oſcillating body. See CENTRE *of Oſcillation*.

OSCULATION, in Geometry, denotes the contact between any curve and its oſculatory circle, that is, the circle of the ſame curvature with the given curve, at the point of contact or of Oſculation. If AC be the evolute of the involute curve AEF, and the tangent CE the radius of curvature at the point E, with which, and the centre C, if the circle BEG be deſcribed; this circle is ſaid to oſculate or kiſs the curve AEF in the point E, which point E Mr. Huygens calls the point of Oſculation, or kiſſing point.

The line CE is called the oſculatory radius, or the radius of curvature; and the circle BEG the oſculatory or kiſſing circle.

The

The evolute AC is the locus of the centres of all the circles that oſculate the involute curve AEF.



OSCULATION alſo means the point of concourſe of two branches of a curve which touch each other. For example, if the equation of a curve be $y = \sqrt{x} + \sqrt[4]{x^3}$, it is eaſy to ſee that the curve has two branches touching one another at the point where $x = 0$, becauſe the roots have each the ſigns + and −.

The point of Oſculation differs from the cuſp or point of retroceſſion (which is alſo a kind of point of contact of two branches) in this, that in this latter caſe the two branches terminate, and paſs no farther, but in the former the two branches exiſt on both ſides of the point of Oſculation. Thus, in the ſecond figure above, the point B is the Oſculation of the two branches ABD, EBF; but C, though it is alſo a tangent point, is a cuſp or point of retroceſſion, of AC and AB, the branches not paſſing beyond the point A.

OSCULATORY *Circle*, or *Kiſſing Circle*, is the ſame as the circle of curvature; that is, the circle having the ſame curvature with any curve at a given point. See the foregoing article, Oſculation, where BEG, in the laſt figure but one, is the Oſculatory circle of the curve AEF at the point E; and CE the Oſculatory radius, or the radius of curvature.

This circle is called Oſculatory, or kiſſing, becauſe that, of all the circles that can touch the curve in the ſame point, that one touches it the cloſeſt, in ſuch manner that no other ſuch tangent circle can be drawn between it and the curve; ſo that, in touching the curve, it embraces it as it were, both touching and cutting it at the ſame time, being on one ſide at the convex part of the curve, and on the other at the concave part of it.

In a circle, all the Oſculatory radii are equal, being the common radius of the circle; the evolute of a circle being only a point, which is its centre. See ſome properties of the Oſculatory circle in Maclaurin's Algebra, Appendix De Linearum Geometricarum Proprietatibus generalibus Tractatus, Theor. 2, § 15 &c, treated in a pure geometrical manner.

OSCULATORY *Parabola*. See PARABOLA.

OSCULATORY *Point*, the Oſculation, or point of contact between a curve and its Oſculatory circle.

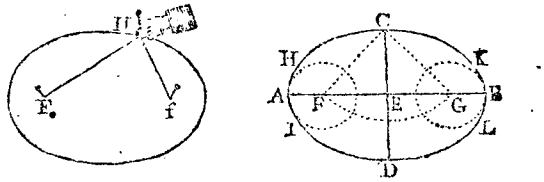
OSTENSIVE *Demonſtrations*, ſuch as plainly and directly demonſtrate the truth of any propoſition. In which they ſtand diſtinguiſhed from Apagogical ones, or reductions ad abſurdum, or ad impoſſibile, which prove the truth propoſed by demonſtrating the abſurdity or impoſſibility of the contrary.

OTACOUSTIC, an inſtrument that aids or improves the ſenſe of hearing. See ACOUSTICS.

OVAL, an oblong curvilinear figure, having two unequal diameters, and bounded by a curve line returning into itſelf. Or a figure contained by a ſingle curve line, imperfectly round, its length being greater than its breadth, like an egg: whence its name.

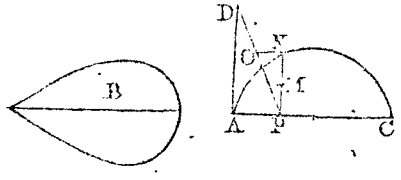
The proper Oval, or egg-ſhape, is an irregular figure, being narrower at one end than the other; in which it differs from the ellipſe, which is the mathematical Oval, and is equally broad at both ends.—The common people confound the two together: but geometricians call the Oval a Falſe Ellipſe.

The method of deſcribing an Oval chiefly uſed among artificers, is by a cord or ſtring, as FH*f*, whoſe length is equal to the greater diameter of the intended Oval, and which is faſtened by its extremes to two points or pins, F and *f*, planted in its longer diameter; then, holding it always ſtretched out as at H, with a pin or pencil carried round the inſide, the Oval is deſcribed: which will be ſo much the longer and narrower as the two fixed points are farther apart. This Oval ſo deſcribed is the true mathematical ellipſe, the points F and *f* being the two foci.



Another popular way to deſcribe an Oval of a given length and breadth, is thus: Set the given length and breadth, AB and CD, to biſect each other perpendicularly at E; with the centre C, and radius AE, deſcribe an arc to croſs AB in F and G; then with theſe centres, F and G, and radii AF and BG, deſcribe two little arcs HI and KL for the ſmaller ends of the Oval; and laſtly, with the centres C and D, and radius CD, deſcribe the arcs HK and IL, for the flatter or longer ſides of the Oval.— Sometimes other points, inſtead of C and D, are to be taken by trial, as centres in the line CD, produced if neceſſary, ſo as to make the two laſt arcs join beſt with the two former ones.

OVAL denotes alſo certain roundiſh figures, of various and pleaſant ſhapes, among curve lines of the higher kinds. Theſe figures are expreſſed by equations of all dimenſions above the 2d, and more eſpecially the even dimenſions, as the 4th, 6th, &c. Of this kind is the equation $a^2y^2 = -x^4 + ax^3$, which denotes the



Oval B, in ſhape of the ſection of a pear through the middle, and is eaſily deſcribed by means of points. For, if

a circle be described whose diameter AC is $= a$, and AD be perpendicular and equal to AC; then taking any point P in AC, joining DP, and drawing PN parallel to AD, and NO parallel to AC; and lastly taking PM $=$ NO, the point M will be one point of the Oval sought.

In like manner the equation

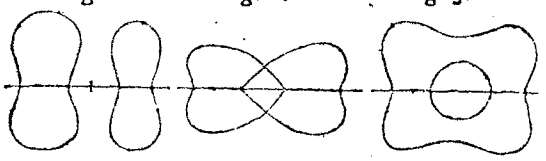
$$y^4 - 4y^2 = -ax^4 + bx^3 + cx^2 + dx + e$$

expresses several very pretty Ovals, among which the following 12 are some of the most remarkable. For when the equation

$$ax^4 = bx^3 + cx^2 + dx + e$$

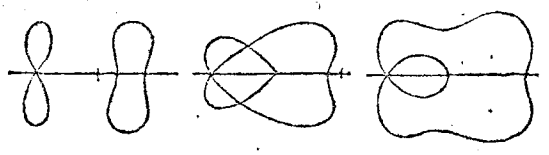
has four real unequal roots, the given equation will denote the three following species, in fig. 1, 2, 3:

Fig. 1. Fig. 2. Fig. 3.



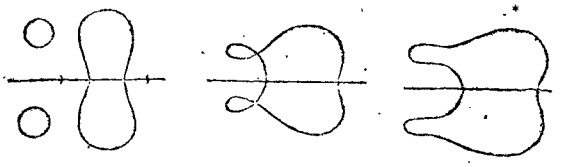
When the two less roots are equal, the three species will be expressed as in fig. 4, 5, 6, thus:

Fig. 4. Fig. 5. Fig. 6.



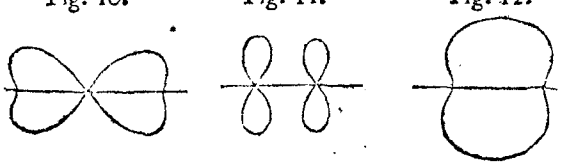
When the two less roots become imaginary, it will denote the three species as exhibited in fig. 7, 8, 9:

Fig. 7. Fig. 8. Fig. 9.



When the two middle roots are equal, the species will be as appears in fig. 10: when two roots are equal, and two more so, the species will be as in fig. 11: and when the two middle roots become imaginary, the species will be as appears in fig. 12:

Fig. 10. Fig. 11. Fig. 12.



OUGHTRED (William), an eminent English mathematician and divine, was born at Eton in Buckinghamshire, 1573, and educated in the school there; whence he was elected to King's-college in Cambridge in 1592, where he continued about 12 years, and became a fellow; employing his time in close application to useful studies, particularly the mathematical sciences, which he contributed greatly, by his example and exhortation, to bring into vogue among his acquaintances there.

About 1603 he quitted the university, and was presented to the rectory of Aldbury, near Guildford in Surry, where he lived a long retired and studious life, seldom travelling so far as London once a year; his recreation being a diversity of studies: "as often, says he, as I was tired with the labours of my own profession, I have allayed that tediousness by walking in the pleasant, and more than Elysian Fields of the diverse and various parts of human learning, and not of the mathematics only." About the year 1628 he was appointed by the earl of Arundel tutor to his son lord William Howard, in the mathematics, and his Clavis was drawn up for the use of that young nobleman. He always kept up a correspondence by letters with some of the most eminent scholars of his time, upon mathematical subjects: the originals of which were preserved, and communicated to the Royal Society, by William Jones, Esq. The chief mathematicians of that age owed much of their skill to him; and his house was always full of young gentlemen who came from all parts to receive his instruction: nor was he without invitations to settle in France, Italy, and Holland. "He was as facetious, says Mr. David Lloyd, in Greek and Latin, as solid in arithmetic, geometry, and the sphere, of all measures, music, &c; exact in his style as in his judgment; handling his tube and other instruments at 80 as steadily as others did at 30; owing this, as he said, to temperance and exercise; principling his people with plain and solid truths, as he did the world with great and useful arts; advancing new inventions in all things but religion, which he endeavoured to promote in its primitive purity, maintaining that prudence, meekness, and simplicity were the great ornaments of his life.

Notwithstanding Oughtred's great merit, being a strong royalist, he was in danger, in 1646, of a sequestration by the committee for plundering ministers; several articles being deposed and sworn against him: but upon his day of hearing, William Lilly, the famous astrologer, applied to Sir Bulstrode Whitlocke and all his old friends; who appeared so numerous in his behalf, that though the chairman and many other Presbyterian members were active against him, yet he was cleared by the majority. This is told us by Lilly himself, in the History of his own Life, where he styles Oughtred the most famous mathematician then of Europe.—He died in 1660, at 86 years of age, and was buried at Aldbury. It is said he died of a sudden ecstasy of joy, about the beginning of May, on hearing the news of the vote at Westminster, which passed for the restoration of Charles the 2d.—He left one son, whom he put apprentice to a watch-maker, and wrote a book of instructions in that art for his use.

He published several works in his life time; the principal of which are the following:

1. *Arithmeticæ*

1. *Arithmeticæ in Numero & Speciebus Inſtitutio*, in 8vo, 1631. This treatiſe he intended ſhould ſerve as a general Key to the Mathematics. It was afterwards reprinted, with conſiderable alterations and additions, in 1648, under the title of *A Key to the Mathematics*. It was alſo publiſhed in Engliſh, with ſeveral additional tracts; viz, one on the Reſolution of all ſorts of Affected Equations in Numbers; a ſecond on Compound Intereſt; a third on the eaſy Art of Delineating all manner of Plain Sun-dials; alſo a Demonſtration of the Rule of Falſe-Poſition. A 3d edition of the ſame work was printed in 1652, in Latin, with the ſame additional tracts, together with ſome others, viz, On the Uſe of Logarithms; A Declaration of the 10th book of Euclid's Elements; a treatiſe of Regular Solids; and the Theorems contained in the books of Archimedes.

2. *The Circles of Proportion*, and a *Horizontal Inſtrument*; in 1633, 4to; publiſhed by his ſcholar Mr. William Foſter.

3. *Deſcription and Uſe of the Double Horizontal Dial*; 1636, 8vo.

4. *Trigonometria*: his treatiſe on Trigonometry, in Latin, in 4to, 1657: And another edition in Engliſh, together with Tables of Sines, Tangents, and Secants.

He left behind him a great number of papers upon mathematical ſubjects; and in moſt of his Greek and Latin mathematical books, there were found notes in his own hand writing, with an abridgment of almoſt every propoſition and demonſtration in the margin, which came into the muſeum of the late William Jones Eſq. F. R. S. Theſe books and manuſcripts then paſſed into the hands of his friend Sir Charles Scarborough the phyſician; the latter of which were carefully looked over, and all that were found fit for the preſs, printed at Oxford in 1676, in 8vo, under the title of

5. *Opuſcula Mathematica hactenus inedita*. This collection contains the following pieces: (1), Inſtitutiones Mechanicæ: (2), De Variis Corporum Generibus Gravitate & Magnitudine comparatis: (3), Automata: (4), Quæſtiones Diophanti Alexandrini, libri tres: (5), De Triangulis Planis Rectangulis: (6), De Diviſione Superficierum: (7), Muſicæ Elementa: (8), De Propugnaculorum Munitionibus: (9), Sectiones Angulares.

6. In 1660, Sir Jonas Moore annexed to his Arithmetic a treatiſe entitled, "*Conical Sections*; or, The ſeveral Sections of a Cone; being an Analyſis or Methodical Contraction of the two firſt books of Mydorgius, and whereby the nature of the Parabola, Hyperbola, and Ellipſis, is very clearly laid down. Tranſlated from the papers of the learned William Oughtred."

Oughtred, though undoubtedly a very great mathematician, was yet far from having the happieſt method of treating the ſubjects he wrote upon. His ſtyle and manner were very conciſe, obſcure, and dry; and his rules and precepts ſo involved in ſymbols and abbreviations, as rendered his mathematical writings very troubleſome to read, and difficult to be underſtood. Beſide the characters and abbreviations before made uſe of in Algebra, he introduced ſeveral others; as

× to denote multiplication;

:: for proportion or ſimilitude of ratios;

÷ for continued proportion;

⊐ } for greater and leſs; &c.
⊏ }

OUNCE, a ſmall weight, being the 16th part of a pound avoirdupois; and the 12th part of a pound troy.—The avoirdupois Ounce is divided into 16 drachms or drams; alſo the Ounce troy into 24 pennyweights, and the pennyweight into 24 grains.

OVOLO, in Architecture, a round moulding, whoſe profile or ſweep, in the Ionic and Compoſite capital, is uſually a quadrant of a circle; whence it is alſo popularly called the Quarter round.

OUTWARD *Flanking Angle*, or the *Angle of the Tenaille*, is that comprehended by the two flanking lines of defence.

OUTWORKS, in Fortification, all thoſe works made on the outſide of the ditch of a fortified place, to cover and defend it.

Outworks, called alſo Advanced and Detached Works, are thoſe which not only ſerve to cover the body of the place, but alſo to keep the enemy at a diſtance, and prevent them from taking advantage of the cavities and elevations uſually found in the places about the counterſcarp; which might ſerve them either as lodgments, or as rideaux, to facilitate the carrying on their trenches, and planting their batteries againſt the place. Such are ravelins, tenailles, hornworks, queue d'arondes, envelopes, and crownworks. Of theſe, the moſt uſual are ravelins, or halfmoons, formed between the two baſtions, on the flanking angle of the counterſcarp, and before the curtain, to cover the gates and bridges.

It is a general rule in all Outworks, that if there be ſeveral of them, one before another, to cover one and the ſame tenaille of a place, the nearer ones muſt gradually, and one after another, command thoſe which are fartheſt advanced out into the campagne; that is, muſt have higher ramparts, that ſo they may overlook and fire upon the beſiegers, when they are maſters of the more outward works.

The gorges alſo of all Outworks ſhould be plain, and without parapets; leſt, when taken, they ſhould ſerve to ſecure the beſiegers againſt the fire of the rêtiring beſieged; whence the gorges of Outworks are only palliſadoed, to prevent a ſurprize.

OX-EYE, in Optics. See SCIOPTIC, and CAMERA *Obſcura*.

OXGANG, or OXGATE, of land, is uſually taken for 15 acres; being as much land as it is ſuppoſed one ox can plow in a year. In Lincolnſhire they ſtill corruptly call it Oſkin of land.—In Scotland, the term is uſed for a portion of arable land, containing 13 acres.

OXYGONE, in Geometry, is acute-angled, meaning a figure conſiſting wholly of acute angles, or ſuch as are leſs than 90 degrees each.—The term is chiefly applied to triangles, where the three angles are all acute.

OXYGONIAL, is acute-angular.

OZANAM (JAMES), an eminent French mathematician, was deſcended from a family of Jewiſh extraction, but which had long been converts to the Romiſh faith; and ſome of whom had held conſiderable places in the parliaments of Provence. He was born at Boligneux in Breſſia, in the year 1640; and being a younger

ſon,

ſon, though his father had a good eſtate, it was thought proper to breed him to the church, that he might enjoy ſome ſmall benefices which belonged to the family, to ſerve as a proviſion for him. Accordingly he ſtudied divinity four years; but then, on the death of his father, he devoted himſelf entirely to the mathematics, to which he had always been ſtrongly attached. Some mathematical books, which fell into his hands, firſt excited his curioſity; and by his extraordinary genius, without the aid of a maſter, he made ſo great a progreſs, that at the age of 15 he wrote a treatiſe of that kind.

For a maintenance, he firſt went to Lyons to teach the mathematics; which anſwered very well there; and after ſome time his generous diſpoſition procured him ſtill better ſucceſs elſewhere. Among his ſcholars were two foreigners, who expreſſing their uneaſineſs to him, at being diſappointed of ſome bills of exchange for a journey to Paris; he aſked them how much would do, and being told 50 piſtoles, he lent them the money immediately, even without their note for it. Upon their arrival at Paris, mentioning this generous action to M. Dagueſſeau, father of the chancellor, this magiſtrate was touched with it; and engaged them to invite Ozanam to Paris, with a promiſe of his favour. The opportunity was eagerly embraced; and the buſineſs of teaching the mathematics here ſoon brought him in a conſiderable income: but he wanted prudence for ſome time to make the beſt uſe of it. He was young, handſome, and ſprightly; and much addicted both to gaming and gallantry, which continually drained his purſe. Among others, he had a love intrigue with a woman, who lodged in the ſame houſe with him, and gave herſelf out for a perſon of condition. However, this expence in time led him to think of matrimony, and he ſoon after married a young woman without a fortune. She made amends for this defect however by her modeſty, virtue, and ſweet temper; ſo that though the ſtate of his purſe was not amended, yet he had more home-felt enjoyment than before, being indeed completely happy in her, as long as ſhe lived. He had twelve children by her, who moſtly all died young; and he was laſtly rendered quite unhappy by the death of his wife alſo, which happened in 1701. Neither did this misfortune come ſingle: for the war breaking out about the ſame time, on account of the Spaniſh ſucceſſion, it ſwept away all his ſcholars, who, being foreigners, were obliged to leave Paris. Thus he ſunk into a very melancholy ſtate; under which however he received ſome relief, and amuſement, from the honour of being admitted this ſame year an eleve of the Royal Academy of Sciences.

He ſeems to have had a pre-ſentiment of his death, from ſome lurking diſorder within, of which no outward ſymptoms appeared. In that perſuaſion he refuſed to engage with ſome foreign noblemen, who offered to become his ſcholars; alleging that he ſhould not live long enough to carry them through their intended courſe. Accordingly he was ſeized ſoon after with an apoplexy, which terminated his exiſtence in leſs than two hours, on the 3d of April 1717, at 77 years of age.

Ozanam was of a mild and calm diſpoſition, a chearful and pleaſant temper, endeared by a generoſity almoſt unparalleled. His manners were irreproachable after marriage; and he was ſincerely pious, and zealouſly devout, though ſtudiouſly avoiding to meddle in theological queſtions. He uſed to ſay, that it was the buſineſs of the Sorbonne to diſcuſs, of the pope to decide, and of a mathematician to go ſtraight to heaven in a perpendicular line. He wrote a great number of uſeful books; a liſt of which is as follows:

1. A treatiſe of Practical Geometry; 12mo, 1684.
2. Tables of Sines, Tangents and Secants; with a treatiſe of Trigonometry; 8vo, 1685.
3. A treatiſe of Lines of the Firſt Order; of the Conſtruction of Equations; and of Geometric Lines, &c; 4to, 1687.
4. The Uſe of the Compaſſes of Proportion, &c; with a treatiſe on the Diviſion of Lands; 8vo, 1688.
5. An Univerſal Inſtrument for readily reſolving Geometrical Problems without calculation; 12mo, 1688.
6. A Mathematical Dictionary; 4to, 1690.
7. A General Method for drawing Dials, &c; 12mo, 1693.
8. A Courſe of Mathematics, in 5 volumes, 8vo, 1693.
9. A treatiſe on Fortification, Ancient and Modern; 4to, 1693.
10. Mathematical and Philoſophical Recreations; 2 vols 8vo, 1694; and again with additions in 4 vols, 1724.
11. New Treatiſe on Trigonometry; 12mo, 1699.
12. Surveying, and meaſuring all ſorts of Artificers Works; 12mo, 1699.
13. New Elements of Algebra; 2 vols 8vo, 1702.
14. Theory and Practice of Perſpective; 8vo, 1711.
15. Treatiſe of Coſmography and Geography; 8vo, 1711.
16. Euclid's Elements, by De Chales, corrected and enlarged; 12mo, 1709.
17. Boulanger's Practical Geometry enlarged, &c; 12mo, 1691.
18. Boulanger's treatiſe on the Sphere corrected and enlarged; 12mo.

Ozanam has alſo the following pieces in the *Journal des Sçavans*: viz, (1), Demonſtration of this theorem, that neither the Sum nor the Difference of two Fourth Powers, can be a Fourth Power; Journal of May 1680.—(2), Anſwer to a Problem propoſed by M. Comiers; Journal of Nov. 17, 1681.—(3), Demonſtration of a Problem concerning Falſe and Imaginary Roots; Journal of April 2 and 9, 1685.—(4), Method of finding in Numbers the Cubic and Surſolid Roots of a Binomial, when it has one; Journal of April 9, 1691.

Alſo in the *Memoires de Trevoux*, of December 1703, he has this piece, viz, Anſwer to certain articles of Objection to the firſt part of his Algebra.

And laſtly, in the Memoirs of the Academy of Sciences, of 1707, he has Obſervations on a Problem of Spherical Trigonometry.

P.

PAG

PAGAN (Blaise François Comte de), an eminent French mathematician and engineer, was born at Avignon in Provence, 1604; and took to the profeſſion of a ſoldier at 14 years of age. In 1620 he was employed at the ſiege of Caen, in the battle of Pont de Cé, and the reduction of the Navareins, and the reſt of Béarn; where he ſignalized himſelf, and acquired a reputation far above his years. He was preſent, in 1621, at the ſiege of St. John d'Angeli, as alſo that of Clarac and Montauban, where he loſt an eye by a muſket-ſhot. After this time, there happened neither ſiege, battle, nor any other occaſion, in which he did not ſignalize himſelf by ſome effort of courage and conduct. At the paſſage of the Alps, and the barricade of Suza, he put himſelf at the head of the Forlorn Hope, compoſed of the braveſt youths among the guards; and undertook to arrive the firſt at the attack, by a private way which was extremely dangerous; when, having gained the top of a very ſteep mountain, he cried out to his followers, "There lies the way to glory!" Upon which, ſliding along this mountain, they came firſt to the attack; when immediately commencing a furious onſet, and the army coming to their aſſiſtance, they forced the barricades. When the king laid ſiege to Nancy in 1633, Pagan attended him, in drawing the lines and forts of circumvallation.—In 1642 he was ſent to the ſervice in Portugal, as field-marſhal; and the ſame year he unfortunately loſt the ſight of his other eye by a diſtemper, and thus became totally blind.

But though he was thus prevented from ſerving his country with his conduct and courage in the field, he reſumed the vigorous ſtudy of fortification and the mathematics; and in 1645 he gave the public a treatiſe on the former ſubject, which was eſteemed the beſt extant.—In 1651 he publiſhed his *Geometrical Theorems*, which ſhewed an extenſive and critical knowledge of his ſubject.—In 1655 he printed a *Paraphraſe of the Account of the River of Amazons*, by father de Rennes; and, though blind, it is ſaid he drew the chart of the river and the adjacent parts of the country, as in that work.—In 1657 he publiſhed *The Theory of the Planets*, cleared from that multiplicity of eccentric cycles and epicycles, which the aſtronomers had invented to explain their motions. This work diſtinguiſhed him among aſtronomers as much as that of Fortification had among engineers. And in 1658 he printed his *Aſtronomical Tables*, which are plain and ſuccinct.

Few great men are without ſome foible: Pagan's was that of a prejudice in favour of judicial aſtrology; and though he is more reſerved than moſt others on that head, yet we cannot place what he did on that ſubject among thoſe productions which do honour to his underſtanding. He was beloved and reſpected by all perſons illuſtrious for rank as well as ſcience; and his houſe was the rendezvous of all the polite and learned both in city and court.—He died at Paris, univerſally regretted, Nov. 18, 1665.

PAL

Pagan had an univerſal genius; and, having turned his attention chiefly to the art of war, and particularly to the branch of Fortification, he made extraordinary progreſs and improvements in it. He underſtood mathematics not only better than is uſual for a gentleman whoſe view is to puſh his fortune in the army, but even to a degree of perfection ſuperior to that of the ordinary maſters who teach that ſcience. He had ſo particular a genius for this kind of learning, that he acquired it more readily by meditation than by reading authors upon it; and accordingly he ſpent leſs time in ſuch books than he did in thoſe of hiſtory and geography. He had alſo made morality and politics his particular ſtudy; ſo that he may be ſaid to have drawn his own character in his *Homme Heroïque*, and to have been one of the completeſt gentlemen of his time.—Having never married, that branch of his family, which removed from Naples to France in 1552, became extinct in his perſon.

PALILICUM, the ſame as Aldebaran, a fixed ſtar of the firſt magnitude, in the eye of the Bull, or ſign Taurus.

PALISADES, or Palisadoes, in Fortification, ſtakes or ſmall piles driven into the ground, in various ſituations, as ſome defence againſt the ſurprize of an enemy. They are uſually about 6 or 7 inches ſquare, and 9 or 10 feet long, driven about 3 feet into the ground, and 6 inches apart from each other, being braced together by pieces nailed acroſs them near the tops; and ſecured by thick poſts at the diſtance of every 4 or 5 yards.

Palisades are placed in the covert-way, parallel to and at 3 feet diſtance from the parapet or ridge of the glacis, to ſecure it againſt a ſurprize. They are alſo uſed to fortify the avenues of open forts, gorges, half-moons, the bottoms of ditches, the parapets of covert-ways; and in general all places liable to ſurprize, and eaſy of acceſs.

Palisades are uſually planted perpendicularly; though ſome make an angle inclining out towards the enemy, that the ropes caſt over them, to tear them up, may ſlip.

PALLADIO (Andrew), a celebrated Italian architect in the 16th century, was a native of Vicenza in Lombardy, and the diſciple of Triffin, a learned man, who was a Patrician, or Roman nobleman, of the ſame

town of Vicenza. Palladio was one of thoſe, who laboured particularly to reſtore the ancient beauties of architecture, and contributed greatly to revive a true taſte in that art. Having learned the principles of it, he went to Rome; where, applying himſelf with great diligence to ſtudy the ancient monuments, he entered into the ſpirit of their architects, and poſſeſſed himſelf with all their beautiful ideas. This enabled him to reſtore their rules, which had been corrupted by the barbarous Goths. He made exact drawings of the principal works of antiquity which were to be met with at Rome; to which he added *Commentaries*, which went through ſeveral impreſſions, with the figures. This, though a very uſeful work, yet is greatly exceeded by the four books of architecture, which he publiſhed in 1570. The laſt book treats of the Roman temples, and is executed in ſuch a manner, as gives him the preference to all his predeceſſors upon that ſubject. It was tranſlated into French by Roland Friatt, and into Engliſh by ſeveral authors. Inigo Jones wrote ſome excellent remarks upon it, which were publiſhed in an edition of Palladio by Leoni, 1742, in 2 volumes folio.

PALLETS, in Clock and Watch Work, are thoſe pieces or levers which are connected with the pendulum or balance, and receive the immediate impulſe of the ſwing-wheel, or balance-wheel, ſo as to maintain the vibrations of the pendulum in clocks, and of the balance in watches.—The Pallets in all the ordinary conſtructions of clocks and watches, are formed on the verge or axis of the pendulum or balance, and are of various lengths and ſhapes, according to the conſtruction of the piece, or the fancy of the artiſt.

PALLIFICATION, or PILING, in Architecture, denotes the piling of the ground-work, or the ſtrengthening it with piles, or timber driven into the ground; which is practiſed when buildings are erected upon a moiſt or marſhy ſoil.

PALLISADES. See PALISADES.

PALM, an ancient long meaſure, taken from the extent of the hand.

The Roman Palm was of two kinds: the great Palm, taken from the length of the hand, anſwered to our ſpan, and contained 12 fingers, digits, or fingers breadths, or 9 Roman inches, equal to about $8\frac{1}{2}$ Engliſh inches. The ſmall Palm, taken from the breadth of the hand, contained 4 digits or fingers, equal to about 3 Engliſh inches.

The Greek Palm, or Doron, was alſo of two kinds. The ſmall contained 4 fingers, equal to little more than 3 inches. The great Palm contained 5 fingers. The Greek double Palm, called Dichas, contained alſo in proportion.

The Modern Palm is different in different places where it is uſed. It contains,

	Inc.	Lines
At Rome - - -	8	$3\frac{1}{2}$
At Naples, according to Riccioli,	8	0
Ditto, according to others, -	8	7
At Genoa - - -	9	9
At Morocco and Fez - -	7	2
Languedoc, and ſome other parts of France,	9	9
The Engliſh Palm is - - -	3	0

PALM-SUNDAY, the laſt Sunday in Lent, or the Sunday next before Eaſter-Day. So called, from the primitive days, on account of a pious ceremony then in uſe, of bearing Palms, in memory of the triumphant entry of Jeſus Chriſt into Jeruſalem, eight days before the feaſt of the paſſover.

PAPPUS, a very eminent Greek mathematician of Alexandria towards the latter part of the 4th century, particularly mentioned by Suidas, who ſays he flouriſhed under the emperor Theodoſius the Great, who reigned from the year 379 to 395 of Chriſt. His writings ſhew him to have been a conſummate mathematician. Many of his works are loſt, or at leaſt have not yet been diſcovered. Suidas mentions ſeveral of his works, as alſo Voſſius *de Scientiis Mathematicis*. The principal of theſe are, his *Mathematical Collections*, in 8 books, the firſt and part of the ſecond being loſt. He wrote alſo a *Commentary upon Ptolomy's Almageſt*; an *Univerſal Chorography*; *A Deſcription of the Rivers of Libya*; A Treatiſe of *Military Engines*; *Commentaries upon Ariſtarchus of Samos, concerning the Magnitude and Diſtance of the Sun and Moon*; &c. Of theſe, there have been publiſhed, The Mathematical Collections, in a Latin tranſlation, with a large Commentary, by Commandine, in folio, 1588; and a ſecond edition of the ſame in 1660. In 1644, Merſenne exhibited a kind of abridgment of them in his Synopſis Mathematica, in 4to: but this contains only ſuch propoſitions as could be underſtood without figures. In 1655, Meibomius gave ſome of the Lemmata of the 7th book, in his Dialogue upon Proportions. In 1688, Dr. Wallis printed the laſt 12 propoſitions of the 2d book, at the end of his Ariſtarchus Samius. In 1703, Dr. David Gregory gave part of the preface of the 7th book, in the Prolegomena to his Euclid. And in 1706, Dr. Halley gave that Preface entire, in the beginning of his Apollonius.

As the contents of the principal work, the Mathematical Collections, are exceedingly curious, and no account of them having ever appeared in Engliſh, I ſhall here give a very brief analyſis of thoſe books, extracted from my notes upon this author.

Of the Third Book—The ſubjects of the third book conſiſt chiefly of three principal problems; for the ſolution of which, a great many other problems are reſolved, and theorems demonſtrated. The firſt of theſe three problems is, To find Two Mean Proportionals between two given lines—The 2d problem is, To find, what are called, three Medietates in a ſemicircle; where, by a Medietas is meant a ſet of three lines in continued proportion, whether arithmetical, or geometrical, or harmonical; ſo that to find three medietates, is to find an arithmetical, a geometrical, and an harmonical ſet of three terms each. And the third problem is, From ſome points in the baſe of a triangle, to draw two lines to meet in a point within the triangle, ſo that their ſum ſhall be greater than the ſum of the other two ſides which are without them. A great many curious properties are premiſed to each of theſe problems; then their ſolutions are given according to the methods of ſeveral ancient mathematicians, with an hiſtorical account of them, and his own demonſtrations; and laſtly, their applications to various matters of great importance. In his hiſtorical anecdotes, many curious things are preſerved concerning mathematicians that were ancient

even in his time, which we ſhould otherwiſe have known nothing at all about.

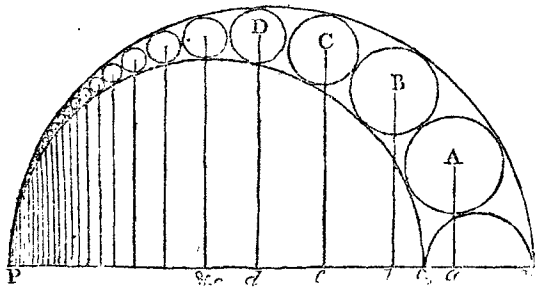
In order to the ſolution of the firſt of the three problems above mentioned, he begins by premiſing four general theorems concerning proportions. Then follows a diſſertation on the nature and diviſion of problems by the Ancients, into Plane, Solid, and Linear, with examples of them, taken out of the writings of Eratoſthenes, Philo, and Hero. A ſolution is then given to the problem concerning two mean proportionals, by four different ways, namely according to Eratoſthenes, Nicomedes, Hero, and after a way of his own, in which he not only doubles the cube, but alſo finds another cube in any proportion whatever to a given cube.

For the ſolution of the ſecond problem, he lays down very curious definitions and properties of *mediętates* of all ſorts, and ſhews how to find them all in a great variety of caſes, both as to what the Ancients had done in them, and what was done by others whom he calls the Moderns. *Mediętas* ſeems to have been a general term invented to expreſs three lines, having either an arithmetical, or a geometrical, or an harmonical relation; for the words proportion (or ratio), and analogy (or ſimilar proportions), are reſtricted to a geometrical relation only. But he ſhews how all the mediętates may be expreſſed by analogies.

The ſolution of the 3d problem leads Pappus out into the conſideration of a number of admirable and ſeemingly paradoxical problems, concerning the inflecting of lines to a point within triangles, quadrangles, and other figures, the ſum of which ſhall exceed the ſum of the ſurrounding exterior lines.

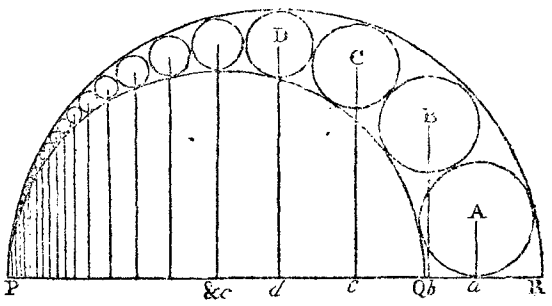
Finally, a number of other problems are added, concerning the inſcription of all the regular bodies within a ſphere. The whole being effected in a very general and pure mathematical way; making all together 58 propoſitions, viz, 44 problems and 14 theorems.

Of the 4th Book of Pappus.— In the 4th book are firſt premiſed a number of theorems relating to triangles, parallelograms, circles, with lines in and about circles, and the tangencies of various circles: all preparatory to this curious and general problem, viz, relative to an infinite ſeries of circles inſcribed in the ſpace, called ἄρβελον, *arbelon*, contained between the circumferences of two circles touching inwardly. Where it is ſhewn, that if the infinite ſeries of circles be inſcribed in the manner of this firſt figure, where three ſemicircles are deſcribed on the lines PR, PQ, QR, and



the perpendiculars A*a* B*b*, C*c*, &c, let fall from the centres of the ſeries of inſcribed circles; then the property of theſe perpendiculars is this, viz, that the firſt perpendicular A*a* is equal to the diameter or double the radius of the circle A; the ſecond perpendicular B*b* equal to double the diameter or 4 times the radius of the ſecond circle B; the third perpendicular C*c* equal to 3 times the diameter or 6 times the radius of the third circle C; and ſo on, the ſeries of perpendiculars being to the ſeries of the diameters, as 1, 2, 3, 4, &c, to 1,
or to the ſeries of radii, as 2, 4, 6, 8, &c, to 1.

But if the ſeveral ſmall circles be inſcribed in the



manner of this ſecond circle, the firſt circle of the ſeries touching the part of the line QR; then the ſeries of perpendiculars A*a*, B*b*, C*c*, &c, will be 1, 3, 5, 7, &c, times the radii of the circles A, B, C, D, &c; viz, according to the ſeries of odd numbers; the former proceeding by the ſeries of even numbers.

He next treats of the Helix, or Spiral, propoſed by Conon, and reſolved by Archimedes, demonſtrating its principal properties: in the demonſtration of ſome of which, he makes uſe of the ſame principles as Cavallerius did lately, adding together an infinite number of infinitely ſhort parallelograms and cylinders, which he imagines a triangle and cone to be compoſed of.—He next treats of the properties of the Conchoid which Nicomedes invented for doubling the cube: applying it to the ſolution of certain problems concerning Inclinations, with the finding of two mean proportionals, and cubes in any proportion whatever.—Then of the τετραγωνίζουσα, or Quadratrix, ſo called from its uſe in ſquaring the circle, for which purpoſe it was invented and employed by Dinoſtratus, Nicomedes, and others: the uſe of which however he blames, as it requires poſtulates equally hard to be granted, as the problem itſelf to be demonſtrated by it.—Next he treats of Spirals, deſcribed on planes, and on the convex ſurfaces of various bodies.—From another problem, concerning Inclinations, he there ſhews, how to triſect a given angle; to deſcribe an hyperbola, to two given aſymptotes, and paſſing through a given point; to divide a given arc or angle in any given ratio; to cut off arcs of equal lengths from unequal circles; to take arcs and angles in any proportion, and arcs equal to right lines; with parabolic and hyperbolic loci, which laſt is one of the inclinations of Archimedes.

Of the 5th Book of Pappus.—This book opens with reflections on the different natures of men and brutes, the former acting by reaſon and demonſtration, the latter by inſtinct, yet ſome of them with a certain portion of reaſon or foreſight, as bees, in the curious ſtructure of their cells, which he obſerves are of ſuch a form

a form as to complete the ſpace quite around a point, and yet require the leaſt materials to build them, to contain the ſame quantity of honey. He ſhews that the triangle, ſquare, and hexagon, are the only regular polygons capable of filling the whole ſpace round a point; and remarks that the bees have choſen the fitteſt of theſe; proving afterwards, in the propoſitions, that of all regular figures of the ſame perimeter, that is of the largeſt capacity which has the greateſt number of ſides or angles, and conſequently that the circle is the moſt capacious of all figures whatever.

And thus he finiſhes this curious book on Iſoperimetrical figures, both plane and ſolid; in which many curious and important properties are ſtrictly demonſtrated, both of planes and ſolids, ſome of them being old in his time, and many new ones of his own. In fact, it ſeems he has here brought together into this book, all the properties relating to iſoperimetrical figures then known, and their different degrees of capacity. In the laſt theorem of the book, he has a diſſertation to ſhew, that there can be no more regular bodies beſide the five Platonic ones, or, that only the regular triangles, ſquares, and pentagons, will form regular ſolid angles.

Of the 6th Book of Pappus.—In this book he treats of certain ſpherical properties, which had been either neglected, or improperly and imperfectly treated by ſome celebrated authors before his time.—— Such are ſome things in the 3d book of Theodoſius's Spherics, and in his book on Days and Nights, as alſo ſome in Euclid's Phenomena. For the ſake of theſe, he premiſes and intermixes many curious geometrical properties, eſpecially of circles of the ſphere, and ſpherical triangles. He adverts to ſome curious caſes of variable quantities; ſhewing how ſome increaſe and decreaſe both ways to infinity; while others proceed only one way by increaſe or decreaſe, to infinity, and the other way to a certain magnitude; and others again both ways to a certain magnitude, giving a maximum and minimum.—Here are alſo ſome curious properties concerning the perſpective of the circles of the ſphere, and of other lines. Alſo the locus is determined of all the points from whence a circle may be viewed, ſo as to appear an ellipſe, whoſe centre is a given point within the circle; which locus is ſhewn to be a ſemicircle paſſing through that point.

Of the 7th Book of Pappus.—In the introduction to this book, he deſcribes very particularly the nature of the mathematical compoſition and reſolution of the Ancients, diſtinguiſhing the particular proceſs and uſes of them, in the demonſtration of theorems and ſolution of problems. He then enumerates all the analytical books of the Ancients, or thoſe proceeding by reſolution, which he does in the following order, viz, 1ſt, Euclid's Data, in one book: 2d, Apollonius's Section of a Ratio, 2 books: 3d, his Section of a Space, 2 books: 4th, his Tangencies, 2 books; 5th, Euclid's Poriſms, 3 books: 6th, Apollonius's Inclinations, 2 books: 7th, his Plane Loci, 2 books: 8th, his Conics, 8 books: 9th, Ariſtæus's Solid Loci, 5 books: 10th, Euclid's Loci in Superficies, 2 books; and 11th, Eratoſthenes's Medietates, 2 books. So that all the books are 31, the arguments or contents of which he exhibits, with the number of the Loci, determinations, and caſes, &c; with a multitude of lemmas and propoſitions laid down and demonſtrated; the whole making 238 propoſitions, of the moſt curious geometrical principles and properties, relating to thoſe books.

Of the 8th Book of Pappus.—The 8th book is altogether on Mechanics. It opens with a general oration on the ſubject of mechanics; defining the ſcience, enumerating the different kinds and branches of it, and giving an account of the chief authors and writings on it. After an account of the centre of gravity, upon which the ſcience of mechanics ſo greatly depends, he ſhews in the firſt propoſition, that ſuch a point really exiſts in all bodies. Some of the following propoſitions are alſo concerning the properties of the centre of gravity. He next comes to the Inclined Plane, and in prop. 9, ſhews what power will draw a given weight up a given inclined plane, when the power is given which can draw the weight along a horizontal plane. In the 10th prop. concerning the moving a given weight with a given power, he treats of what the Ancients called a Gloſſocomum, which is nothing more than a ſeries of Wheels-and-axles, in any proportions, turning each other, till we arrive at the given power. In this propoſition, as well as in ſeveral other places, he refers to ſome books that are now loſt; as Archimedes on the Balance, and the Mechanics of Hero and of Philo. Then, from prop. 11 to prop. 19, treats on various miſcellaneous things, as, the organical conſtruction of ſolid problems; the diminution of an architectural column; to deſcribe an ellipſe through five given points; to find the axes of an ellipſe organically; to find alſo organically, the inclination of one plane to another, the neareſt point of a ſphere to a plane, the points in a ſpherical ſurface cut by lines joining certain points, and to inſcribe ſeven hexagons in a given circle. Prop. 20, 21, 22, 23, teach how to conſtruct and adapt the *Tympani*, or wheels of the Gloſſocomum to one another, ſhewing the proportions of their diameters, the number of their teeth, &c. And prop. 24 ſhews how to conſtruct the ſpiral threads of a ſcrew.

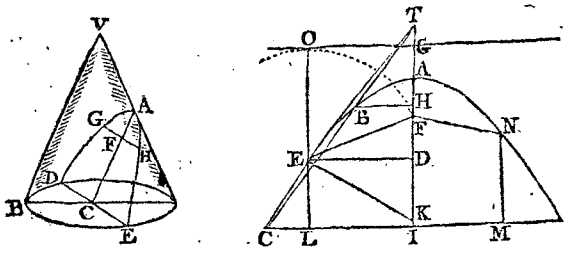
He comes then to the *Five Mechanical Powers, by which a given weight is moved by a given power.* He here propoſes briefly to ſhew what has been ſaid of theſe powers by Hero and Philo, adding alſo ſome things of his own. Their names are, the Axis-in-peritrochio, the Lever, Pulley, Wedge and Screw; and he obſerves, thoſe authors ſhewed how they are all reduced to one principle, though their figures be very different. He then treats of each of theſe powers ſeparately, giving their figures and properties, their conſtruction and uſes.

He next deſcribes the manner of drawing very heavy weights along the ground, by the machine Chelone, which is a kind of ſledge placed upon two looſe rollers, and drawn forward by any power whatever, a third roller being always laid under the fore part of the Chelone, as one of the other two is quitted and left behind by the motion of the Chelone. In fact this is the ſame machine as has always been employed upon many occaſions in moving very great weights to moderate diſtances.

Finally, Pappus deſcribes the manner of raiſing great weights to a height by the combination of mechanic powers,

powers, as by cranes, and other machines; illuſtrating this, and the former parts, by drawings of the machines that are deſcribed.

PARABOLA, in Geometry, a figure ariſing from the ſection of a cone, when cut by a plane parallel to one of its ſides, as the ſection ADE parallel to the ſide VB of the cone. See CONIC *Sections*, where ſome general properties are given.



Some other Properties of the Parabola.

1. From the ſame point of a cone only one Parabola can be drawn; all the other ſections between the Parabola and the parallel ſide of the cone being ellipſes, and all without them hyperbolas. Alſo the Parabola has but one focus, through which the axis AC paſſes; all the other diameters being parallel to this, and infinite in length alſo.

2. The parameter of the axis is a third proportional to any abſciſs and its ordinate; viz, AC : CD :: CD : p the parameter. And therefore if x denote any abſciſs AC, and y the ordinate CD, it will be $x : y :: y : p = \frac{y^2}{x}$ the parameter; or, by multiplying extremes and means, $px = y^2$, which is the equation of the Parabola.

3. The focus F is the point in the axis where the double ordinate GH is equal to the parameter. Therefore, in the equation of the curve $px = y^2$, taking $p = 2y$, it becomes $2yx = y^2$, or $2x = y$, that is 2AF = FH, or AF = $\frac{1}{2}$FH, or the focal diſtance from a vertex AF is equal to half the ordinate there, or = $\frac{1}{4}p$, one-fourth of the parameter.

4. The abſciſſes of a Parabola are to one another, as the ſquares of their correſponding ordinates. This is evident from the general equation of the curve $px = y^2$, where, p being conſtant, x is as y^2.

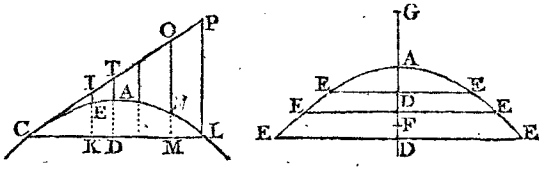
5. The line FE (*fig.* 2 *above*) drawn from the focus to any point of the curve, is equal to the ſum of the focal diſtance and the abſciſs of the ordinate to that point; that is FE = FA + AD = GD, taking AG = AF = $\frac{1}{4}p$. Or EF is always = EO, drawn parallel to DG, to meet the perpendicular GO, called the Directrix.

6. If a line TBC cut the curve of a Parabola in two points, and the axis produced in T, and BH and CI be ordinates at thoſe two points; then is AT a mean proportional between the abſciſſes AH and AI, or $AT^2 = AH . AI$.—And if TE touch the curve, then is AT = AD = the mean between AH and AI.

7. If FE be drawn from the focus to the point of contact of the tangent TE, and EK perpendicular to the ſame tangent; then is FT = FE = FK; and the ſubnormal DK equal to the conſtant quantity 2AF or $\frac{1}{2}p$.

8. The diameter EL being parallel to the axis AK, the perpendicular EK, to the curve or tangent at E, biſects the angle LEF. And therefore all rays of light LE, MN, &c, coming parallel to the axis, will be reflected into the point F, which is therefore called the focus, or burning point; for the angle of incidence LEK is = the angle of reflection KEF.

9. If IEK (*next fig. below*) be any line parallel to the axis, limited by the tangent TC and ordinate CKL to the point of contact; then ſhall IE : EK :: CK : KL. And the ſame thing holds true when CL is alſo in any oblique poſition.



10. The external parts of the parallels IE, TA, ON, PL, &c, are always proportional to the ſquares of their intercepted parts of the tangent; that is,
the external parts IE, TA, ON, PL,
are proportional to CI^2, CT^2, CO^2, CP^2,
or to the ſquares CK^2, CD^2, CM^2, CL^2.

And as this property is common to every poſition of the tangent, if the lines IE, TA, ON, &c, be appended to the points I, T, O, &c, of the tangent, and moveable about them, and of ſuch lengths as that their extremities E, A, N, &c, be in the curve of a Parabola in any one poſition of the tangent; then making the tangent revolve about the point C, the extremities E, A, N, &c, will always form the curve of ſome Parabola, in every poſition of the tangent.

The ſame properties too that have been ſhewn of the axis, and its abſciſſes and ordinates, &c, are true of thoſe of any other diameter. All which, beſides many other curious properties of the Parabola, may be ſeen demonſtrated in my Treatiſe on Conic Sections.

11. *To Conſtruct a Parabola by Points.*

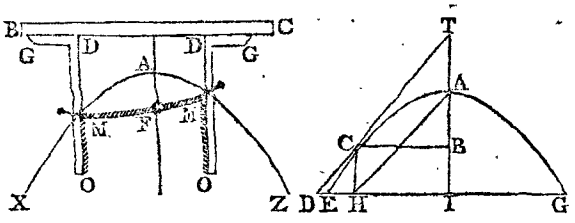
In the axis produced take AG = AF (*laſt fig. above*) the focal diſtance, and draw a number of lines EE, EE, &c, perpendicular to the axis AD; then with the diſtances GD, GD, &c, as radii, and the centre F, deſcribe arcs croſſing the parallel ordinates in E, E, &c. Then with a ſteady hand, or by the ſide of a ſlip of bent whale-bone, draw the curve through all the points E, E, E, &c.

12. *To deſcribe a Parabola by a continued Motion.*

If the rule or the directrix BC be laid upon a plane, (*firſt fig. below*) with the ſquare GDO, in ſuch manner that one of its ſides DG lies along the edge of that rule; and if the thread FMO equal in length to DO, the other ſide of the ſquare, have one end fixed in the extremity of the rule at O, and the other end in ſome point

point F: Then ſlide the ſide of the ſquare DG along the rule BC, and at the ſame time keep the thread continually tight by means of the pin M, with its part MO cloſe to the ſide of the ſquare DO; ſo ſhall the curve AMX, which the pin deſcribes by this motion, be one part of a Parabola.

And if the ſquare be turned over, and moved on the other ſide of the fixed point F, the other part of the ſame Parabola AMZ will be deſcribed.



To draw Tangents to the Parabola.

13. If the point of contact C be given: *(laſt fig. above)* draw the ordinate CB, and produce the axis till AT be = AB; then join TC, which will be the tangent.

14. Or if the point be given in the axis produced: Take AB = AT, and draw the ordinate BC, which will give C the point of contact; to which draw the line TC as before.

15. If D be any other point, neither in the curve nor in the axis produced, through which the tangent is to paſs: Draw DEG perpendicular to the axis, and take DH a mean proportional between DE and DG, and draw HC parallel to the axis, ſo ſhall C be the point of contact, through which and the given point D the tangent DCT is to be drawn.

16. When the tangent is to make a given angle with the ordinate at the point of contact: Take the abſciſs AI equal to half the parameter, or to double the focal diſtance, and draw the ordinate IE: alſo draw AH to make with AI the angle HAI equal to the given angle; then draw HC parallel to the axis, and it will cut the curve in C the point of contact, where a line drawn to make the given angle with CB will be the tangent required.

17. *To find the Area of a Parabola.* Multiply the baſe EG by the perpendicular height AI, and $\frac{2}{3}$ of the product will be the area of the ſpace AEGA; becauſe the Parabolic ſpace is $\frac{2}{3}$ of its circumſcribing parallelogram.

18. *To find the Length of the Curve* AC, commencing at the vertex.—Let y = the ordinate BC, p = the parameter, $q = \frac{2y}{p}$, and $s = \sqrt{1 + q^2}$; then ſhall $\frac{1}{2}p \times (qs +$ hyp. log. of $q + s)$ be the length of the curve AC.

See various other rules for the areas, and lengths of the curve, &c, in my Treatiſe on Menſuration, ſec. 6, pa. 355, &c, 2d edition.

PARABOLAS *of the Higher Kinds*, are algebraic curves, defined by the general equation $a^{n-1}x = y^n$; that is, either $a^2x = y^3$, or $a^3x = y^4$, or $a^4x = y^5$, &c.

Some call theſe by the name of Paraboloids: and in particular, if $a^2x = y^3$, they call it a Cubical Paraboloid; if $a^3x = y^4$, they call it a Biquadratical Paraboloid, or a Surſolid Paraboloid. In reſpect of theſe, the Parabola of the Firſt Kind, above explained, they call the Apollonian, or Quadratic Parabola.

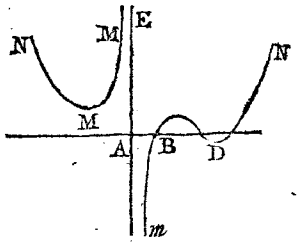
Thoſe curves are alſo to be referred to Parabolas, that are expreſſed by the general equation $ax^{n-1} = y^n$, where the indices of the quantities on each ſide are equal, as before; and theſe are called Semi-Parabolas: as $ax^2 = y^3$ the Semi-Cubical Parabola; or $ax^3 = y^4$ the Semi-Biquadratical Parabola; &c.

They are all comprehended under the more general equation $a^m x^n = y^{m+n}$, where the two indices on one ſide are ſtill equal to the index on the other ſide of the equation; which include both the former kinds of equations, as well as ſuch as theſe following ones, $a^2x^2 = y^4$, or $a^2x^3 = y^5$, or $a^4x^3 = y^7$, &c.

Carteſian PARABOLA, is a curve of the 2d order expreſſed by the equation

$$xy = ax^3 + bx^2 + cx + d,$$

containing four infinite legs, viz two hyperbolic ones



MM and Bm, to the common aſymptote AE, tending contrary ways, and two Parabolic legs MN and DN joining them, being Newton's 66th ſpecies of lines of the 3d order, and called by him a Trident. It is made uſe of by Des Cartes in the 3d book of his Geometry, for finding the roots of equations of 6 dimenſions, by means of its interſections with a circle. Its moſt ſimple equation is $xy = x^3 + g^3$. And points through which it is to paſs may be eaſily found by means of a common Parabola whoſe abſciſs is $ax^2 + bx + c$, and an hyperbola whoſe abſciſs is $\frac{d}{x}$; for y will be equal to the ſum or difference of the correſponding ordinates of this Parabola and hyperbola.

Des Cartes, in the place abovementioned, ſhews how to deſcribe this curve by a continued motion. And Mr. Maclaurin does the ſame thing in a different way, in his Organica Geometria.

Diverging PARABOLA, is a name given by Newton to a ſpecies of five different lines of the 3d order, expreſſed by the equation

$$y^2 = ax^3 + bx^2 + cx + d.$$

The

The firſt is a bell-form Parabola, with an oval at its head (*fig.* 1.); which is the caſe when the equation $o = ax^3 + bx^2 + cx + d$, has three real and unequal roots; ſo that one of the moſt ſimple equations of a curve of this kind is $py^2 = x^3 + ax^2 + a^2x$.

Fig 1.

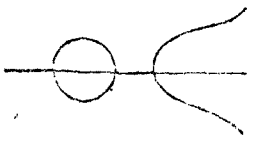


Fig. 2.

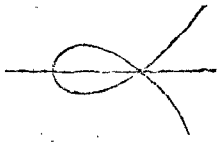

Fig. 3.

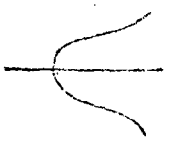

Fig. 4.

The 2d is alſo a bell-form Parabola, with a conjugate point, or infinitely ſmall oval, at the head (*fig.* 1.); being the caſe when the equation $o = ax^3 + bx^2 + cx + d$ has its two leſs roots equal; the moſt ſimple equation of which is $py^2 = x^3 + ax^2$.

The third is a Parabola, with two diverging legs, croſſing one another like a knot (*fig.* 2.); which happens when the equation $o = ax^3 + bx^2 + cx + d$ has its two greater roots equal; the more ſimple equation being $py^2 = x^3 + ax^2$.

The fourth a pure bell-form Parabola (*fig.* 3.); being the caſe when $o = ax^3 + bx^2 + cx + d$ has two imaginary roots; and its moſt ſimple equation is $py^2 = x^3 + a^3$, or $py^2 = x^3 + a^2x$.

The fifth a Parabola with two diverging legs, forming at their meeting a cuſp or double point (*fig.* 4); being the caſe when the equation $o = ax^3 + bx^2 + cx + d$ has three equal roots; ſo that $py^2 = x^3$ is the moſt ſimple equation of this curve, which indeed is the Semicubical, or Neilian Parabola.

If a ſolid generated by the rotation of a ſemi-cubical Parabola, about its axis, be cut by a plane, each of theſe five Parabolas will be exhibited by its ſections. For, when the cutting plane is oblique to the axis, but falls below it, the ſection is a diverging Parabola, with an oval at its head. When oblique to the axis, but paſſes through the vertex, the ſection is a diverging Parabola, having an infinitely ſmall oval at its head. When the cutting is oblique to the axis, falls below it, and at the ſame time touches the curve ſurface of the ſolid, as well as cuts it, the ſection is a diverging Parabola, with a nodus or knot. When the cutting plane falls above the vertex, either parallel or oblique to the axis, the ſection is a pure diverging Parabola. And laſtly when the cutting plane paſſes through the axis, the ſection is the ſemi-cubical Parabola from which the ſolid was generated.

PARABOLIC *Aſymptote*, is uſed for a Parabolic line approaching to a curve, ſo that they never meet; yet by producing both indefinitely, their diſtance from each other becomes leſs than any given line.

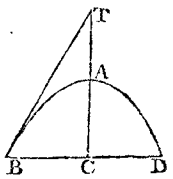
There may be as many different kinds of theſe Aſymptotes as there are parabolas of different orders. When a curve has a common parabola for its Aſymptote, the ratio of the ſubtangent to the abſciſs approaches continually to the ratio of 2 to 1, when the axis of the parabola coincides with the baſe; but this ratio of the ſubtangent to the abſciſs approaches to that of 1 to 2, when the axis is perpendicular to the baſe. And by obſerving the limit to which the ratio of the ſubtangent and abſciſs approaches, Parabolic Aſymptotes of various kinds may be diſcovered. See Maclaurin's Fluxions, art. 337.

PARABOLIC *Conoid*, is a ſolid generated by the rotation of a parabola about its axis.

This ſolid is equal to half its circumſcribed cylinder; and therefore if the baſe be multiplied by the height, half the product will be the ſolid content.

To find the Curve Surface of a Parabloid.

Let BAD be the generating parabola, AC = AT, and BT a tangent at B. Put $p = 3{\cdot}1416$, $y = BC$, $x = AC = AT$, and $t = BT = \sqrt{4x^2 + y^2}$; then is the curve ſurface $= \frac{2}{3}ay \times (y + \frac{tt}{t + y})$.



See various other rules and geometrical conſtructions for the ſurfaces and ſolidities of Parabolic Conoids, in my Menſuration, part 3, ſect. 6, 2d edition.

PARABOLIC *Pyramidoid*, is a ſolid figure thus named by Dr. Wallis, from its geneſis, or formation, which is thus: Let all the ſquares of the ordinates of a parabola be conceived to be ſo placed, that the axis ſhall paſs perpendicularly through all their centres; then the aggregate of all theſe planes will form the Parabolic Pyramidoid.

This figure is equal to half its circumſcribed parallelopipedon. And therefore the ſolid content is found by multiplying the baſe by the altitude, and taking half the product; or the one of theſe by half the other.

PARABOLIC *Space*, is the ſpace or area included by the curve line and baſe or double ordinate of the parabola. The area of this ſpace, it has been ſhewn under the article Parabola, is $\frac{2}{3}$ of its circumſcribed parallelogram; which is its quadrature, and which was firſt found out by Archimedes, though ſome ſay by Pythagoras.

PARABOLIC *Spindle*, is a ſolid figure conceived to be formed by the rotation of a parabola about its baſe or double ordinate.

This ſolid is equal to $\frac{8}{15}$ of its circumſcribed cylinder. See my Menſuration, prob. 15, pa. 390, &c, 2d edition.

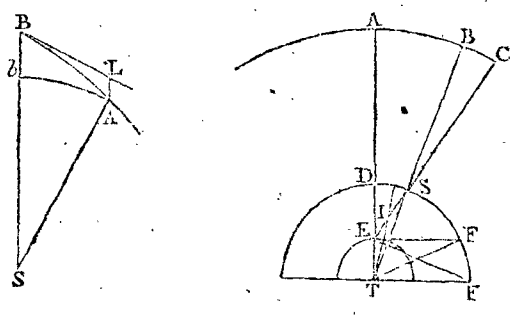
PARABOLIC *Spiral*. See HELICOID *Parabola*.

PARABOLIFORM *Curves*, a name ſometimes given to the parabolas of the higher orders.

PARABOLOIDES, Parabolas of the higher orders.——The equation for all curves of this kind being $a^{m-n}x^n = y^m$, the proportion of the area of any one to the complement of it to the circumſcribing parallelogram, will be as m to n.

PARACENTRIC *Motion*, denotes the ſpace by which a revolving planet approaches nearer to, or recedes farther from, the ſun, or centre of attraction.

Thus, if a planet in A move towards B; then is SB — SA = *b*B the Paracentric motion of that planet: where S is the place of the ſun.



PARACENTRIC *Solicitation of Gravity*, is the ſame as the Vis Centripeta; and is expreſſed by the line AL drawn from the point A, parallel to the ray SB (infinitely near SA), till it interſect the tangent BL.

PARALLACTIC *Angle*, called alſo ſimply PARALLAX, is the angle EST (*laſt fig. above*) made at the centre of a ſtar, &c, by two lines, drawn, the one from the centre of the earth at T, and the other from its ſurface at E.—Or, which amounts to the ſame thing, the Parallactic angle, is the difference of the two angles CEA and BTA, under which the real and apparent diſtances from the zenith are ſeen.

The ſines of the Parallactic angles ELT, EST, at the ſame or equal diſtances DS from the zenith, are in the reciprocal ratio of the diſtances, TL, and TS, from the centre of the earth.

PARALLAX, is an arch of the heavens intercepted between the true place of a ſtar, and its apparent place.

The true place of a ſtar S, is that point of the heavens B, in which it would be ſeen by an eye placed in the centre of the earth at T. And the apparent place, is that point of the heavens C, where a ſtar appears to an eye upon the ſurface of the earth at E.

This difference of places, is what is called abſolutely the Parallax, or the Parallax of Altitude; which Copernicus calls the Commutation; and which therefore is an angle formed by two viſual rays, drawn, the one from the centre, the other from the circumference of the earth, and traverſing the body of the ſtar; being meaſured by an arch of a great circle intercepted between the two points of true and apparent place, B and C.

The PARALLAX *of Altitude* CB is properly the difference between the true diſtance from the zenith AB, and the apparent diſtance AC. Hence the Parallax diminiſhes the altitude of a ſtar, or increaſes its diſtance from the zenith; and it has therefore a contrary effect to the refraction.

The Parallax is greateſt in the horizon, called the Horizontal Parallax EFT. From hence it decreaſes all the way to the zenith D or A, where it is nothing; the real and apparent places there coinciding.

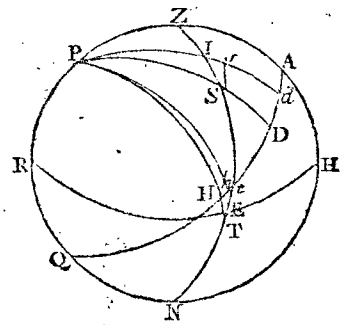
The Horizontal Parallax is the ſame, whether the ſtar be in the true or apparent horizon.

The fixed ſtars have no ſenſible Parallax, by reaſon of their immenſe diſtance, to which the ſemidiameter of the earth is but a mere point.

Hence alſo, the nearer a ſtar is to the earth, the greater is its Parallax; and on the contrary, the farther it is off, the leſs is the Parallax, at an equal elevation above the horizon. So the ſtar at S has a leſs Parallax than the ſtar at I. Saturn is ſo high, that it is difficult to obſerve in him any Parallax at all.

Parallax increaſes the right and oblique aſcenſion, and diminiſhes the deſcenſion; it diminiſhes the northern declination and latitude in the eaſtern part, and increaſes them in the weſtern; but it increaſes the ſouthern declination in the eaſtern and weſtern part; it diminiſhes the longitude in the weſtern part, and increaſes it in the eaſtern. Parallax therefore has juſt oppoſite effects to refraction.

The doctrine of Parallaxes is of the greateſt importance, in aſtronomy, for determining the diſtances of the planets, comets, and other phenomena of the heavens; for the calculation of eclipſes, and for finding the longitude.



PARALLAX *of Right Aſcenſion and Deſcenſion*, is an arch of the Equinoctial D*d*, by which the Parallax of altitude increaſes the aſcenſion, and diminiſhes the deſcenſion.

PARALLAX *of Declination*, is an arch of a circle of declination SI, by which the Parallax of altitude increaſes or diminiſhes the declination of a ſtar.

PARALLAX *of Latitude*, is an arch of a circle of latitude SI, by which the Parallax of altitude increaſes or diminiſhes the latitude.

Menſtrual PARALLAX *of the Sun*, is an angle formed by two right lines; one drawn from the earth to the ſun, and another from the ſun to the moon, at either of their quadratures.

PARALLAX *of the Annual Orbit of the Earth*, is the difference between the heliocentric and geocentric place of a planet, or the angle at any planet, ſubtended by the diſtance between the earth and ſun.

There are various methods for finding the Parallaxes of the celeſtial bodies: ſome of the principal and eaſier of which are as follow:

To Obſerve the PARALLAX *of a Celeſtial Body.*—Obſerve when the body is in the ſame vertical with a fixed ſtar which is near it, and in that poſition meaſure its

apparent diſtance from the ſtar. Obſerve again when the body and ſtar are at equal altitudes from the horizon; and there meaſure their diſtance again. Then the difference of theſe diſtances will be the Parallax very nearly.

To Obſerve the Moon's PARALLAX.—Obſerve very accurately the moon's meridian altitude, and note the moment of time. To this time, equated, compute her true latitude and longitude, and from theſe find her declination; alſo from her declination, and the elevation of the equator, find her true meridian altitude. Subtract the refraction from the obſerved altitude: then the difference between the remainder and the true altitude, will be the Parallax ſought. If the obſerved altitude be not meridional, reduce it to the true altitude for the time of obſervation.

By this means, in 1583, Oct. 12 day 5 h, 19 m. from the moon's meridian altitude obſerved at 13° 38′, Tycho found her Parallax to be 54 minutes.

To Obſerve the Moon's PARALLAX *in an Eclipſe.*—In an eclipſe of the moon obſerve when both horns are in the ſame vertical circle, and at that moment take the altitudes of both horns; then half their ſum will be nearly the apparent altitude of the moon's centre; from which ſubtract the refraction, which gives the apparent altitude freed from refraction. But the true altitude is nearly equal to the altitude of the centre of the ſhadow at that time: now the altitude of the centre of the ſhadow is known, becauſe we know the ſun's place in the ecliptic, and his depreſſion below the horizon, which is equal to the altitude of the oppoſite point of the ecliptic, in which the centre of the ſhadow is. Having thus the true and apparent altitudes, their difference is the Parallax ſought.

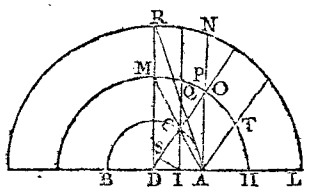
De la Hire makes the greateſt horizontal Parallax 1° 1′ 25″, and the leaſt 54′ 5″. M. le Monnier determined the mean Parallax of the Moon to be 57′ 12″. Others have made it 57′ 18″.

From the Moon's PARALLAX *EST, and altitude SF* (laſt fig. but one); *to find her diſtance from the Earth.*—From her apparent altitude given, there is given her apparent zenith diſtance, i. e. the angle AES; or by her true altitude, the complement angle ATS. Wherefore, ſince at the ſame time, the Parallactic angle S is known, the 3d or ſupplemental angle TES is alſo known. Then, conſidering the earth's ſemidiameter TE as 1, in the triangle TES are given all the angles and the ſide TE, to find ES the moon's diſtance from the ſurface of the earth, or TS her diſtance from the centre.

Thus Tycho, by the obſervation above mentioned, found the moon's diſtance at that time from the earth, was 62 of the earth's ſemidiameters. According to De la Hire's determination, her diſtance when in the perigee is near 56 ſemidiameters, but in her apogee near 63½; and therefore the mean nearly 59¾, or in round numbers 60 ſemidiameters.

Hence alſo, ſince, from the moon's theory, there is given the ratio of her diſtances from the earth in the ſeveral degrees of her anomaly; thoſe diſtances being found, by the rule of three, in ſemidiameters of the earth, the Parallax is thence determined to the ſeveral degrees of the true anomaly.

To Obſerve the PARALLAX *of Mars.*—1. Suppoſe Mars in the meridian and equator at H; and that the obſerver, under the equator in A, obſerves him culminating with ſome fixed ſtar. 2. If now the obſerver were in the centre of the earth, he would ſee Mars conſtantly in the ſame point of the heavens with the ſtar; and therefore, together with it, in the plane of the horizon, or of the 6th horary: but ſince Mars here has ſome ſenſible Parallax, and the fixed ſtar has none, Mars will be ſeen in the horizon, when in P, the plane of the ſenſible horizon; and the ſtar, when in R, the plane of the true horizon: therefore obſerve the time between the tranſit of Mars and of the ſtar through the plane of the 6th hour.—3. Convert this time into minutes of the equator, at the rate of 15 degrees to the hour; by which means there will be obtained the arch PM, to which the angle PAM, and conſequently the angle AMD, is nearly equal; which is the horizontal Parallax of Mars.



If the obſerver be not under the equator, but in a parallel IQ, that difference will be a leſs arch QM: wherefore, ſince the ſmall arches QM and PM are nearly as their ſines AD and ID; and ſince ADG is equal to the diſtance of the place from the equator, i. e. to the elevation of the pole, or the latitude; therefore AD to ID, as radius to the coſine of the latitude; ſay, as the coſine of the latitude ID is to radius, ſo is the Parallax obſerved in I, to the Parallax under the equator.

Since Mars and the fixed ſtar cannot be commodiouſly obſerved in the horizon; let them be obſerved in the circle of the 3d hour: and ſince the Parallax obſerved there TO, is to the horizontal one PM, as IS to ID: ſay, as the ſine of the angle IDS, or 45° (ſince the plane DO is in the middle between the meridian DH and the true horizon DM), is to radius, ſo is the Parallax TO to the horizontal Parallax PM.

If Mars be likewiſe out of the plane of the equator, the Parallax found will be an arch of a parallel; which muſt therefore be reduced, as above, to an arch of the equator.

Laſtly, if Mars be not ſtationary, but either direct or retrograde, by obſervations for ſeveral days find out what his motion is every hour, that his true place from the centre may be aſſigned for any given time.

By this method Caſſini, who was the author of it, obſerved the greateſt horizontal Parallax of Mars to be 25″; but Mr. Flamſteed found it near 30″. Caſſini obſerved alſo the Parallax of Venus by the ſame method.

To Find the Sun's PARALLAX.—The great diſtance of the ſun renders his Parallax too ſmall to fall under even the niceſt immediate obſervation. Many attempts have indeed been made, both by the ancients and moderns, and many methods invented for that purpoſe. The firſt was that of Hipparchus, which was followed by Ptolomy, &c, and was founded on the obſervation of lunar eclipſes.

eclipſes. The ſecond was that of Ariſtarchus, in which the angle ſubtended by the ſemidiameter of the moon's orbit, ſeen from the ſun, was ſought from the lunar phaſes. But theſe both proving deficient, aſtronomers are now forced to have recourſe to the Parallaxes of the nearer planets, Mars and Venus. Now from the theory of the motions of the earth and planets, there is known at any time the proportion of the diſtances of the ſun and planets from us; and the horizontal Parallaxes being reciprocally proportional to thoſe diſtances; by knowing the Parallax of a planet, that of the ſun may be thence found.

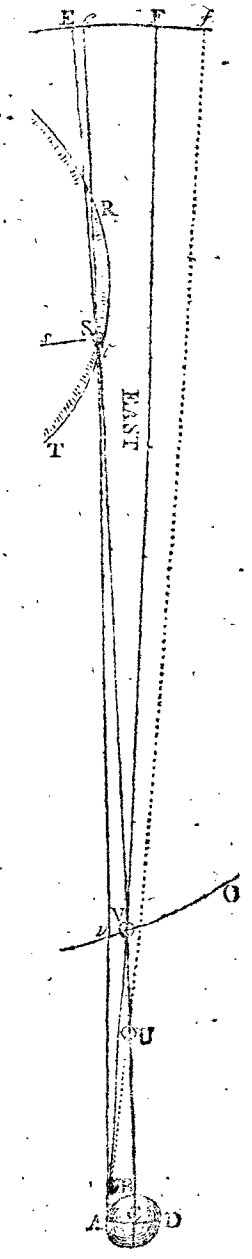
Thus Mars, when oppoſite to the ſun, is twice as near as the ſun is, and therefore his Parallax will be twice as great as that of the ſun. And Venus, when in her inferior conjunction with the ſun, is ſometimes nearer us than he is; and therefore her Parallax is greater in the ſame proportion. Thus, from the Parallaxes of Mars and Venus, Caſſini found the ſun's Parallax to be 10″; from whence his diſtance comes out 22000 ſemidiameters of the earth.

But the moſt accurate method of determining the Parallaxes of theſe planets, and thence the Parallax of the ſun, is that of obſerving their tranſit. However, Mercury, though frequently to be ſeen on the ſun, is not fit for this purpoſe; becauſe he is ſo near the ſun, that the difference of their Parallaxes is always leſs than the ſolar Parallax required. But the Parallax of Venus, being almoſt 4 times as great as the ſolar Parallax, will cauſe very ſenſible differences between the times in which ſhe will ſeem to be paſſing over the ſun at different parts of the earth. With the view of engaging the attention of aſtronomers to this method of determining the ſun's Parallax, Dr. Halley communicated to the Royal Society, in 1691, a paper, containing an account of the ſeveral years in which ſuch a tranſit may happen, computed from the tables which were then in uſe: thoſe at the aſcending node occur in the month of November O. S. in the years 918, 1161, 1396, 1631, 1639, 1874, 2109, 2117; and at the deſcending node in May O. S. in the years 1048, 1283, 1291, 1518, 1526, 1761, 1769, 1996, 2004. Philoſ. Tranſ. Abr. vol. 1, p. 435 &c.

Dr. Halley even then concluded, that if the interval of time between the two interior contacts of Venus with the ſun, could be meaſured to the exactneſs of a ſecond, in two places properly ſituated, the ſun's Parallax might be determined within its 500dth part. And this concluſion was more fully explained in a ſubſequent paper, concerning the tranſit of Venus in the year 1761, in the Philoſ. Tranſ. numb. 348, or Abr. vol. 4, p. 213.

It does not appear that any of the preceding tranſits had been obſerved; except that of 1639, by our ingenious countryman Mr. Horrox, and his friend Mr. Crabtree, of Mancheſter. But Mr. Horrox died on the 3d of January, 1641, at the age of 25, juſt after he had finiſhed his treatiſe, *Venus in Sole viſa*, in which he diſcovers a more accurate knowledge of the dimenſions of the ſolar ſyſtem, than his learned commentator Hevelius.

To give a general idea of this method of determining the horizontal Parallax of Venus, and from thence, by analogy, the Parallax and diſtance of the ſun, and of all the planets from him; let DBA be the earth, V Venus, and TSR the eaſtern limb of the ſun. To an obſerver at B, the point *t* of that limb will be on the meridian, its place referred to the heavens will be at E, and Venus will appear juſt within it at S. But to an obſerver at A, at the ſame inſtant, Venus is eaſt of the ſun, in the right line AVF; the point *t* of the ſun's limb appears at *e* in the heavens, and if Venus were then viſible ſhe would appear at F. The angle CVA is the horizontal Parallax of Venus; which is equal to the oppoſite angle FVE, meaſured by the arc FE. ASC is the ſun's horizontal Parallax, equal to the oppoſite angle *e*SE, meaſured by the arc *e*E; and FA*e* or VA*e* is Venus's horizontal Parallax from the ſun, which may be found by obſerving how much later in abſolute time her total ingreſs on the ſun is, as ſeen from A, than as ſeen from B, which is the time ſhe takes to move from V to *v*, in her orbit OV*v*.



If Venus were nearer the earth, as at U, her horizontal Parallax from the ſun would be the arch *fe*, which meaſures the angle *f*A*e*; and this angle is greater than the angle FA*e*, by the difference of their meaſures F*f*. So that as the diſtance of the celeſtial object from the earth is leſs, its Parallax is the greater.

Now it has been already obſerved, that the horizontal Parallaxes of the planets are inverſely as their diſtances from the earth's centre, therefore as the ſun's diſtance at the time of the tranſit is to Venus's diſtance, ſo is the Parallax of Venus to that of the ſun: and as the ſun's mean diſtance from the earth's centre, is to his diſtance on the day of the tranſit, ſo is his horizontal Parallax on that day, to his horizontal Parallax at the time of his mean diſtance from the earth's centre. Hence his true diſtance in ſemidiameters of the earth may be obtained by the following analogy, viz, as the ſine of the ſun's Parallax is to radius, ſo is unity or the earth's ſemidiameter, to the number of ſemidiameters of the earth in the ſun's diſtance from the centre; which number multiplied by the number of

miles in the earth's ſemidiameter, will give the number of miles in the ſun's diſtance. Then from the proportional diſtances of the planets, determined by the theory of gravity, their true diſtances may be found. And from their apparent diameters at theſe known diſtances, their real diameters and bulks may be found.

Mr. Short, with great labour, deduced the quantity of the ſun's Parallax from the beſt obſervations that were made of the tranſit of Venus, on the 6th of June, 1761, (for which ſee Philoſ. Tranſ. vol. 51 and 52) both in Britain and in foreign parts, and found it to have been 8″·52 on the day of the tranſit, when the ſun was very nearly at his greateſt diſtance from the earth; and conſequently 8″·65 when the ſun is at his mean diſtance from the earth. See Philoſ. Tranſ. vol. 52, p. 611 &c. Whence,

As ſin. 8″·65 - - - -	log.	5·6219140
to radius - - - -		10·0000000
So is 1 ſemidiameter - -		0·0000000
to 23882·84 ſemidiameters -		4·3780860

that is, 23882 $\frac{84}{100}$ is the number of the earth's ſemidiameters contained in its diſtance from the ſun; and this number of ſemidiameters being multiplied by 3985, the number of Engliſh miles contained in the earth's ſemidiameter, (though later obſervations make this ſemidiameter only 3956½ miles), there is obtained 95,173,127 miles for the earth's mean diſtance from the ſun. And hence, from the analogies under the article DISTANCE, the mean diſtances of all the reſt of the planets from the ſun, in miles, are found as follow, viz,

Mercury's diſtance - -	36,841,468
Venus's diſtance - -	68,891,486
Mars's diſtance - -	145,014,148
Jupiter's diſtance - -	494,990,976
Saturn's diſtance - -	907,956,130.

In another paper (Philoſ. Tranſ. vol. 53, p. 169) Mr. Short ſtates the mean horizontal Parallax of the ſun at 8″·69. And Mr. Hornſby, from ſeveral obſervations of the tranſit of June 3d, 1769 (for which ſee the Philoſ. Tranſ. vol. 59) deduces the ſun's Parallax for that day equal to 8·65, and the mean Parallax 8″·78; whence he makes the mean diſtance of the earth from the ſun to be 93,726,900 Engliſh miles, and the diſtances of the other planets thus:

Mercury's diſtance - -	36,281,700
Venus's diſtance - -	67,795,500
Mars's diſtance - -	142,818,000
Jupiter's diſtance - -	487,472,000
Saturn's diſtance - -	894,162,000

See the Philoſ. Tranſ. vol. 61, p. 572.

But others, by taking the reſults of thoſe obſervations that are moſt to be depended on, have made the ſun's Parallax at his mean diſtance from the earth to be 8·6045; and ſome make it only 8·54. According to the former of theſe, the ſun's mean diſtance from the earth is 95,109,736 miles; and according to the latter it is 95,834,742 miles. Upon the whole there ſeems reaſon to conclude that the ſun's horizontal Parallax may be ſtated at 8″·6, and his diſtance near 95 millions of miles. Hence, the following horizontal Parallaxes:

Mean Parallax of the ſun -	0′	8″·6
Moon's greateſt - -	61	32
Moon's leaſt - - -	54	4
Moon's mean - - -	57	48
Mars's - - -	0	25

Of the PARALLAX *of the Fixed Stars.* As to the fixed ſtars, their diſtance is ſo great, that it has never been found that they have any ſenſible Parallax, neither with reſpect to the earth's diameter, nor even with regard to the diameter of the earth's annual orbit round the ſun, although this diameter be about 190 millions of miles. For, any of thoſe ſtars being obſerved from oppoſite ends of this diameter, or at the interval of half a year between the obſervations, when the earth is in oppoſite points of her orbit, yet ſtill the ſtar appears in the ſame place and ſituation in the heavens, without any change that is ſenſible, or meaſurable with the very beſt inſtruments, not amounting to a ſingle ſecond of a degree. That is, the diameter of the earth's annual orbit, at the neareſt of the fixed ſtars, does not ſubtend an angle of a ſingle ſecond; or, in compariſon of the diſtance of the fixed ſtars, the extent of 190 millions of miles is but as a point!

PARALLAX is alſo uſed, in Levelling, for the angle contained between the line of true level, and that of apparent level. And, in other branches of ſcience, for the difference between the true and apparent places.

PARALLEL, in Geometry, is applied to lines, figures, and bodies, which are every where equidiſtant from each other; or which, though infinitely produced, would never either approach nearer, or recede farther from, each other; their diſtance being every where meaſured by a perpendicular line between them. Hence,

PARALLEL *right lines* are thoſe which, though infinitely produced ever ſo far, would never meet: which is Euclid's definition of them.

Newton, in Lemma 22, book 1 of his Principia, defines Parallels to be ſuch lines as tend to a point infinitely diſtant.

Parallel Lines ſtand oppoſed to lines converging, and diverging.

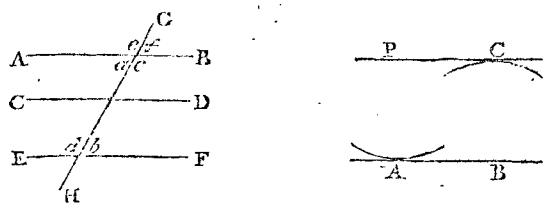
Some define an inclining or converging line, to be that which will meet another at a finite diſtance, and a Parallel line, that which will only meet at an infinite diſtance.

As a perpendicular is by ſome ſaid to be the ſhorteſt of all lines that can be drawn to another; ſo a Parallel is ſaid to be the longeſt.

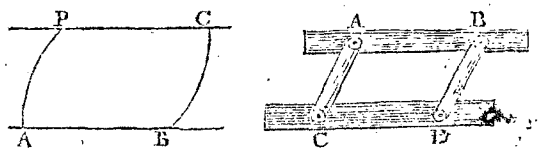
It is demonſtrated by geometricians, that two lines, AB and CD, that are both Parallel to one and the ſame right line EF, are alſo Parallel to each other. And that if two Parallel lines AB and EF be cut by any other line GH; then 1ſt, the alternate angles are equal; viz the angle $a = \angle b$, and $\angle c = \angle d$. 2d, The external angle is equal to the internal one on the ſame ſide of the cutting line; viz. the $\angle e = \angle d$, and the $\angle f = \angle b$. 3d, That the two internal ones on the ſame ſide are, taken together, equal to two

right

right angles; viz, $\angle a + \angle d = 180°$, or $\angle c + \angle b = 180°$.



To draw a PARALLEL *Line.*—If the line to be Parallel to AB muſt paſs through a given point P: Take the neareſt diſtance between the point P and the given line AB, by ſetting one foot of the compaſſes in P, and with the other deſcribe an arc juſt to touch the line in A; then with that diſtance as a radius, and a centre B taken any where in the line, deſcribe another arc C; laſtly, through P draw a line PC juſt to touch the arc C, and that will be the Parallel ſought.



Otherwiſe.—With the centre P, and any radius, deſcribe an arc BC, cutting the given line in B. Next, with the ſame radius, and centre B, deſcribe another arc PA, cutting alſo the given line in A. Laſtly, take AP between the compaſſes, and apply it from B to C; and through P and C draw the Parallel PC required.

Or, draw the line with the Parallel Ruler, deſcribed below, by laying one edge of the ruler along AB, and extending the other to the given point or diſtance.

When the one line is to be at a given diſtance from the other; take that diſtance between the compaſſes as a radius, and with two centres taken any where in the given line, deſcribe two arcs; then lay a ruler juſt to touch the arcs, and by it draw the Parallel.

PARALLEL *Planes*, are every where equidiſtant, or have all the perpendiculars that are drawn between them, everywhere equal.

PARALLEL *Rays*, in Optics, are thoſe which keep always at an equal diſtance in reſpect to each other, from the viſual object to the eye, from which the object is ſuppoſed to be infinitely diſtant.

PARALLEL *Ruler*, is a mathematical inſtrument, conſiſting of two equal rulers, AB and CD, either of wood or metal, connected together by two ſlender croſs bars or blades AC and BD, moveable about the points or joints A, B, C, D.

There are other forms of this inſtrument, a little varied from the above; ſome having the two blades croſſing in the middle, and fixed only at one end of them, the other two ends ſliding in grooves along the two rulers; &c.

The uſe of this inſtrument is obvious. For the edge of one of the rulers being applied to any line, the other opened to any extent will be always parallel to the former; and conſequently any Parallels to this may be drawn by the edge of the ruler, opened to any extent.

PARALLEL *Sailing*, in Navigation, is the ſailing on or under a Parallel of latitude, or Parallel to the equator. —Of this there are three caſes.

1. Given the Diſtance and Difference of Longitude; to find the Latitude.—Rule. As the difference of longitude is to the diſtance, ſo is radius to the coſine of the latitude.

2. Given the Latitude and Difference of Longitude; to find the Diſtance.—Rule. As radius is to the coſine of the latitude, ſo is the difference of longitude to the diſtance.

3. Given the Latitude and Diſtance; to find the difference of longitude.—Rule. As the coſine of latitude is to radius, ſo is the diſtance to the difference of longitude.

PARALLEL *Sphere*, is that ſituation of the ſphere where the equator coincides with the horizon, and the poles with the zenith and nadir.

In this ſphere all the Parallels of the equator become Parallels of the horizon; conſequently no ſtars ever riſe or ſet, but all turn round in circles Parallel to the horizon, as well as the ſun himſelf, which when in the equinoctial wheels round the horizon the whole day. Alſo, After the ſun riſes to the elevated pole, he never ſets for ſix months; and after his entering again on the other ſide of the line, he never riſes for ſix months longer.

This poſition of the ſphere is theirs only who live at the poles of the earth, if any ſuch there be. The greateſt height the ſun can riſe to them, is $23\frac{1}{2}$ degrees. They have but one day and one night, each being half a year long. See SPHERE.

PARALLELS, or *Places of Arms*, in a Siege, are deep trenches, 15 or 18 feet wide, joining the ſeveral attacks together; and ſerving to place the guard of the trenches in, to be at hand to ſupport the workmen when attacked.

There are uſually three in an attack: the firſt is about 600 yards from the covert-way, the ſecond between 3 and 400, and the third near or on the glacis. —It is ſaid they were firſt invented or uſed by Vauban.

PARALLELS *of Altitude*, or Almacantars, are circles Parallel to the horizon, conceived to paſs through every degree and minute of the meridian between the horizon and zenith; having their poles in the zenith.

PARALLELS, or PARALLEL *Circles*, called alſo Parallels of Latitude, and Circles of Latitude, are leſſer circles of the ſphere, Parallel to the equinoctial or equator.

PARALLELS *of Declination*, are leſſer circles Parallel to the equinoctial.

PARALLELS *of Latitude*, in Geography, are leſſer circles Parallel to the equator. But in Aſtronomy they are Parallel to the ecliptic.

PARALLELISM, the quality of a parallel, or that which denominates it ſuch. Or it is that by which two things, as lines, rays, or the like, become equidiſtant from one another.

PARALLELISM *of the Earth's Axis*, is that invariable ſituation of the axis, in the progreſs of the earth through the annual orbit, by which it always keeps parallel to itſelf; ſo that if a line be drawn parallel to its axis, while

while in any one poſition; the axis, in all other poſitions or parts of the orbit, will always be parallel to the ſame line.

In conſequence of this Parallelism, the axis of the earth points always, as to ſenſe, to the ſame place or point in the heavens, viz to the poles. Becauſe, though really the axis, in the annual motion, deſcribes the ſurface of a cylinder, whoſe baſe is the circle of the earth's annual orbit, yet this whole circle is but as a point in compariſon with the diſtance of the fixed ſtars; and therefore all the ſides of the cylinder ſeem to tend to the ſame point, which is the celeſtial pole.—To this Parallelism is owing the change and variety of ſeaſons, with the inequality of days and nights.

This Parallelism is the neceſſary conſequence of the earth's double motion; the one round the ſun, the other round its own axis. Nor is there any neceſſity to imagine a third motion, as ſome have done, to account for this Parallelism.

Parallelism *of Rows of Trees.* The eye placed at the end of an alley bounded by two rows of trees, planted in parallel lines, never ſees them parallel, but always inclining to each other, towards the farther end.

Hence mathematicians have taken occaſion to enquire, in what lines the trees muſt be diſpoſed, to correct this effect of the perſpective, and make the rows ſtill appear parallel. And, to produce this effect, it is evident that the unequal intervals of any two oppoſite or correſponding trees may be ſeen under equal viſual angles.

For this purpoſe, M. Fabry, Tacquet, and Varignon obſerve, that the rows muſt be oppoſite ſemi-hyperbolas. See the Mem. Acad. Sciences, an. 1717.

But notwithſtanding the ingenuity of their ſpeculations, it has been proved by D'Alembert, and Bouguer, that to produce the effect propoſed, the trees are to be ranged merely in two diverging right lines.

PARALLELOGRAM, in Geometry, is a quadrilateral right-lined figure, whoſe oppoſite ſides are parallel to each other.

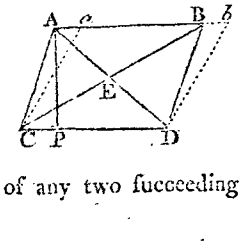
A Parallelogram may be conceived as generated by the motion of a right line, along a plane, always parallel to itſelf.

Parallelograms have ſeveral particular denominations, and are of ſeveral ſpecies, according to certain particular circumſtances, as follow:

When the angles of the Parallelogram are right ones, it is called a Rectangle.—When the angles are right, and all its ſides equal, it is a ſquare.—When the ſides are equal, but the angles oblique ones, the figure is a Rhombus or Lozenge. And when both the ſides and angles are unequal, it is a Rhomboides.

Every other quadrilateral whoſe oppoſite ſides are neither parallel nor equal, is called a Trapezium.

Properties of the Parallelogram.—1. In every Parallelogram ABDC, the diagonal divides the figure into two equal triangles, ABD, ACD. Alſo the oppoſite angles and ſides are equal, viz, the ſide AB = CD, and AC = BD, alſo the angle A = ∠ D, and the ∠ B = ∠ C. And the ſum of any two ſucceeding angles, or next the ſame ſide, is equal to two right angles, or 180 degrees, as ∠ A + ∠ C = ∠ C + ∠ D = ∠ D + ∠ B = ∠ B + ∠ A = two right-angles.



2. All Parallelograms, as ABDC and *ab*DC, are equal, that are on the ſame baſe CD, and between the ſame parallels A*b*, CD; or that have either the ſame or equal baſes and altitudes; and each is double a triangle of the ſame or equal baſe and altitude.

3. The areas of Parallelograms are to one another in the compound ratio of their baſes and altitudes. If their baſes be equal, the areas are as their altitudes; and if the altitudes be equal, the areas are as the baſes. And when the angles of the one Parallelogram are equal to thoſe of another, the areas are as the rectangles of the ſides about the equal angles.

4. In every Parallelogram, the ſum of the ſquares of the two diagonals, is equal to the ſum of the ſquares of all the four ſides of the figure, viz,
$AD^2 + BC^2 = AB^2 + BD^2 + DC^2 + CA^2$.
Alſo the two diagonals biſect each other; ſo that AE = ED, and BE = EC.

5. *To find the Area of a* Parallelogram.—Multiply any one ſide, as a baſe, by the height, or perpendicular let fall upon it from the oppoſite ſide. Or, multiply any two adjacent ſides together, and the product by the fine of their contained angle, the radius being 1: viz,
The area is = CD × AP = AC × CD × ſin. ∠ C.

Complement of a Parallelogram. See Complement.

Centre of Gravity of a Parallelogram. See Centre *of Gravity*, and Centrobaric *Method.*

Parallelogram, or Parallelism, or Pentagraph, alſo denotes a machine uſed for the ready and exact reduction or copying of deſigns, ſchemes, plans, prints, &c, in any proportion. See Pentagraph.

Parallelogram *of the Hyperbola*, is the Parallelogram formed by the two aſymptotes of an hyperbola, and the parallels to them, drawn from any point of the curve. This term was firſt uſed by Huygens, at the end of his Diſſertatio de Cauſa Gravitatis. This Parallelogram, ſo formed, is of an invariable magnitude in the ſame hyperbola; and the rectangle of its ſides is equal to the power of the hyperbola.

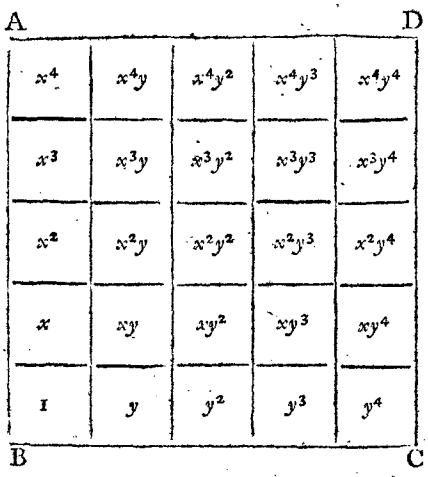
This Parallelogram is alſo the modulus of the logarithmic ſyſtem; and if it be taken as unity or 1, the hyperbolic ſectors and ſegments will correſpond to Napier's or the natural logarithms; for which reaſon theſe have been called the hyperbolic logarithms. If the Parallelogram be taken = ·434294481 90 &c, theſe ſectors and ſegments will repreſent Briggs's logarithms; in which caſe the two aſymptotes of the hyperbola make between them an angle of 25° 44′ 25″½.

Newtonian or Analytic Parallelogram, a term uſed for an invention of Sir Iſaac Newton, to find the firſt term of an infinite converging ſeries. It is ſometimes called the Method of the Parallelogram and Ruler; becauſe a ruler or right line is alſo uſed in it.

This Analytical Parallelogram is formed by dividing any geometrical Parallelogram into equal ſmall ſquares or Parallelograms, by lines drawn horizontally and perpendicularly.

pendicularly through the equal divisions of the sides of the Parallelogram. The small cells, thus formed, are filled with the dimensions or powers of the species x and y, and their products.

For instance, the powers of y, as y^0 or 1, y, y^2, y^3, y^4, &c, being placed in the lowest horizontal range of cells; and the powers of x, as $x^0 = 1$, x, x^2, x^3, &c, in the vertical column to the left; or vice versa; these powers and their products will stand as in this figure:



Now when any literal equation is proposed, involving various powers of the two unknown quantities x and y, to find the value of one of these in an infinite series of the powers of the other; mark such of the cells as correspond to all its terms, or that contain the same powers and products of x and y; then let a ruler be applied to two, or perhaps more, of the Parallelograms so marked, of which let one be the lowest in the left hand column at AB, the other touching the ruler towards the right hand; and let all the rest, not touching the ruler, lie above it. Then select those terms of the equation which are represented by the cells that touch the ruler, and from them find the first term or quantity to be put in the quotient.

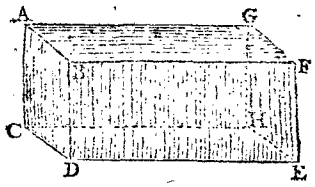
Of the application of this rule, Newton has given several examples in his Method of Fluxions and Infinite Series, p. 9 and 10, but without demonstration; which has been supplied by others. See Colson's Comment on that treatise, p. 192 & seq. Also Newton's Letter to Oldenburg, Oct. 24, 1676. Maclaurin's Algebra, p. 251. And especially Cramer's Analyses des Lignes Courbes, p. 148.—This author observes, that this invention, which is the true foundation of the method of series, was but imperfectly understood, and not valued as it deserved, for a long time. He thinks it however more convenient in practice to use the Analytical Triangle of the abbé de Gua, which takes in no more than the diagonal cells lying between A and C, and those which lie between them and B.

PARALLELOGRAM *Protractor*, a mathematical instrument, consisting of a semicircle of brass, with four rulers in form of a Parallelogram, made to move to any angle. One of these rulers is an index, which shews on the semicircle the quantity of any inward and outward angle.

PARALLELOPIPED, or PARALLELOPIPEDON, is a solid figure contained under six parallelograms, the opposites of which are equal and parallel. Or, it is a prism whose base is a parallelogram.

Properties of the PARALLELOPIPEDON.—All Parallelopipedons, whether right or oblique, that have their bases and altitudes equal, are equal; and each equal to triple a pyramid of an equal base and altitude.—A diagonal plane divides the Parallelopipedon into two equal triangular prisms.—See other properties under the general term PRISM, of which this is only a particular species.

To Measure the Surface and Solidity of a PARALLELOPIPEDON.—Find the areas of the three parallelograms AD, BE, and BG, which add into one sum; and double that sum will be the whole surface of the Parallelopipedon.



For the Solidity; multiply the base by the altitude; that is, any one face or side by its distance from the opposite side; as AD × DE, or AB × BE, or EG × BD.

PARAMETER, a certain constant right line in each of the three Conic Sections; otherwise called also Latus Rectum.

This line is called Parameter, or equal measurer, because it measures the conjugate axis by the same ratio which is between the two axes themselves; being indeed a third proportional to them; viz, a third proportional to the transverse and conjugate axes, in the ellipse and hyperbola; and, which is the same thing, a third proportional to any abscis and its ordinate in the parabola. So if t and c be the two axes in the ellipse and hyperbola, and x and y an abscis and its ordinate in the parabola;

then $t : c :: c : p = \frac{c^2}{t}$ the Param. in the former,

and $x : y :: y : p = \frac{y^2}{x}$ the Param. in the last.

The Parameter is equal to the double ordinate drawn through the focus of any of the three conic sections.

PARAPET, or *Breastwork*, in Fortification, is a defence or screen, on the extreme edge of a rampart, or other work, serving to cover the soldiers and the cannon from the enemy's fire.

The thickness of the Parapet is 18 or 20 feet, commonly lined with masonry; and 7 or 8 feet high, when the enemy has no command above the battery; otherwise, it should be raised higher, to cover the men while they

they load the guns. There are certain openings, called Embrafures, cut in the Parapet, from the top downwards, to within about $2\frac{1}{2}$ or 3 feet of the bottom of it, for the cannon to fire through; the folid pieces of it between one embrafure and another, being called Merlons.

PARAPET is alfo a little breaft-wall, raifed on the brinks of bridges, quays, or high buildings; to ferve as a ftay, and prevent people from falling over.

PARDIES (IGNATIUS GASTON), an ingenious French mathematician and philofopher, was born at Pau, in the province of Gafcony, in 1636; his father being a counfellor of the parliament of that city.—At the age of 16 he entered into the order of Jefuits, and made fo great a proficiency in his ftudies, that he taught polite literature, and compofed many pieces in profe and verfe with a diftinguifhed delicacy of thought and ftyle, before he was well arrived at the age of manhood. Propriety and elegance of language appear to have been his firft purfuits; for which purpofe he ftudied the Belles Lettres, and other learned productions. But afterwards he devoted himfelf to mathematical and philofophical ftudies, and read, with due attention, the moft valuable authors, ancient and modern, in thofe fciences: fo that, in a fhort time he made himfelf mafter of the Peripatetic and Cartefian philofophy, and taught them both with great reputation. Notwithftanding he embraced Cartefianifm, yet he affected to be rather an inventor in philofophy himfelf. In this fpirit he fometimes advanced very bold opinions in natural philofophy, which met with oppofers, who charged him with ftarting abfurdities: but he was ingenious enough to give his notions a plaufible turn, fo as to clear them feemingly from contradictions. His reputation procured him a call to Paris, as Profeffor of Rhetoric in the College of Lewis the Great. He alfo taught the mathematics in that city, as he had before done in other places. He had from his youth a happy genius for that fcience, and made a great progrefs in it; and the glory which his writings acquired him, raifed the higheft expectations from his future labours; but thefe were all blafted by his early death, in 1673, at 37 years of age; falling a victim to his zeal, he having caught a contagious diforder by preaching to the prifoners in the Bicetre.

Pardies wrote with great neatnefs and elegance. His principal works are as follow:

1. Horologium Thaumaticum duplex; 1662, in 4to.
2. Differtatio de Motu et Natura Cometarum; 1665, 8vo.
3. Difcours du Mouvement Local; 1670, 12mo.
4. Elemens de Geometrie; 1670, 12mo.—This has been tranflated into feveral languages; in Engliſh by Dr. Harris, in 1711.
5. Difcours de la Connoiffance des Betes; 1672, 12mo.
6. Lettre d'un Philofophe à un Cartefien de fes amis; 1672, 12mo.
7. La Statique ou la Science des Forces Mouvantes; 1673, 12mo.
8. Defcription et Explication de deux Machines propres à faire des Cadrans avec une grande facilité; 1673, 12mo.
9. Remarques du Mouvement de la Lumiere.
10. Globi Cœleftis in tabula plana redacti Defcriptio; 1675, folio.

Part of his works were printed together, at the Hague, 1691, in 12mo; and again at Lyons, 1725.—Pardies had a difpute alfo with Sir Ifaac Newton, about his New Theory of Light and Colours, in 1672. His letters are inferted in the Philofophical Tranfactions for that year.

PARENT (ANTHONY), a refpectable French mathematician, was born at Paris in 1666. He fhewed an early propenfity to the mathematics, eagerly perufing fuch books in that fcience as fell in his way. His cuftom was to write remarks in the margins of the books he read; and in this way he had filled a number of books with a kind of commentary by the time he was 13 years of age.

Soon after this he was put under a mafter, who taught rhetoric at Chartres. Here he happened to fee a dodecaedron, upon every face of which was delineated a fun-dial, except the loweft on which it ftood. Struck as it were inftantaneoufly with the curiofity of thefe dials, he attempted drawing one himfelf: but having only a book which taught the practical part, without the theory, it was not till after his mafter came to explain the doctrine of the fphere to him, that he began to underftand how the projection of the circles of the fphere formed fun-dials. He then undertook to write a treatife upon gnomonics. To be fure the piece was rude and unpolifhed enough; however, it was entirely his own, and not borrowed. About the fame time he wrote a book of geometry, in the fame taſte, at Beauvais.

His friends then fent for him to Paris to ftudy the law; and in obedience to them he went through a courfe in that faculty: which was no fooner finifhed than, urged by his paffion for mathematics, he fhut himfelf up in the college of Dormans, that no avocation might take him from his beloved ftudy: and, with an allowance of lefs than 200 livres a-year, he lived content in this retreat, from which he never ſtirred but to the Royal College, to hear the lectures of M. de la Hire or M. de Sauveur. When he thought himfelf capable of teaching others, he took pupils: and fortification being a branch of ftudy which the war had brought into particular notice, he had often occafion to teach it: but after fome time he began to entertain fcruples about teaching a fubject he had never feen, knowing it only by imagination. He imparted this fcruple to M. Sauveur, who recommended him to the Marquis d'Aligre, who luckily at that time wanted to have a mathematician with him. M. Parent made two campaigns with the marquis, by which he inftructed himfelf fufficiently in viewing fortified places; of which he drew a number of plans, though he had never learned the art of drawing.

From this period he fpent his time in a continual application to the ftudy of natural philofophy, and mathematics in all its branches, both fpeculative and practical; to which he joined anatomy, botany, and chemiſtry:—his genius joined with his indefatigable application overcoming every thing.

M. de Billettes being admitted into the Academy of Sciences at Paris in 1699, with the title of their mechanician, he named M. Parent for his eleve or difciple,

ciple, a branch of mathematics in which he chiefly excelled. It was ſoon diſcovered in this ſociety, that he engaged in all the different ſubjects which were brought before them; and indeed that he had a hand in every thing. But this extent of knowledge, joined to a natural warmth and impetuoſity of temper, raiſed a ſpirit of contradiction in him, which he indulged on all occaſions; ſometimes to a degree of precipitancy that was highly culpable, and often with but little regard to decency. Indeed the ſame behaviour was returned to him, and the papers which he brought to the academy were often treated with much ſeverity. In his productions, he was charged with obſcurity; a fault for which he was indeed ſo notorious, that he perceived it himſelf, and could not avoid correcting it.

By a regulation of the academy in 1716, the claſs of eleves was ſuppreſſed, as that diſtinction ſeemed to put too great an inequality between the members. M. Parent was made an adjunct or aſſiſtant member for the claſs of geometry: though he enjoyed this promotion but a very ſhort time; being cut off by the ſmall-pox the ſame year, at 50 years of age.

M. Parent, beſides leaving many pieces in manuſcript, publiſhed the following works:

1. Elemens de Mecanique & de Phyſique; in 12mo, 1700.

2. Recherches de Mathematiques & de Phyſique; 3 vols. 4to, 1714.

3. Arithmetique theorico-pratique; in 8vo, 1714.

4. A great multitude of papers in the volumes of the Memoirs of the Academy of Sciences, from the year 1700 to 1714, ſeveral papers in almoſt every volume, upon a variety of branches in the mathematics.

PARGETING, in Building, is uſed for the plaiſtering of walls; ſometimes for plaiſter itſelf.

PARHELION, or PARHELIUM, denotes a mock ſun, or meteor, appearing as a very bright light by the ſide of the ſun; being formed by the reflection of his beams in a cloud properly ſituated.

Parhelia uſually accompany the coronæ, or luminous circles, and are placed in the ſame circumference, and at the ſame height. Their colours reſemble thoſe of the rainbow; the red and yellow are on that ſide towards the ſun, and the blue and violet on the other. Though coronæ are ſometimes ſeen entire, without any Parhelia; and ſometimes Parhelia without coronæ.

The apparent ſize of Parhelia is the ſame as that of the true ſun; but they are not always round, nor always ſo bright as the ſun; and when ſeveral appear, ſome are brighter than others. They are tinged externally with colours like the rainbow, and many of them have a long fiery tail oppoſite to the ſun, but paler towards the extremity. Some Parhelia have been obſerved with two tails and others with three. Theſe tails moſtly appear in a white horizontal circle, commonly paſſing through all the Parhelia, and would go through the centre of the ſun if it were entire. Sometimes there are arcs of leſſer circles, concentric to this, touching thoſe coloured circles which ſurround the ſun: theſe are alſo tinged with colours, and contain other Parhelia.

Parhelia are generally ſituated in the interſections of circles; but Caſſini ſays, thoſe which he ſaw in 1683, were on the outſide of the coloured circle, though the tails were in the circle that was parallel to the horizon. M. Aepinus apprehends, that Parhelia with elliptical coronæ are more frequent in the northern regions, and thoſe with circular ones in the ſouthern. They have been viſible for one, two, three, or four hours together; and it is ſaid that in North America they continue ſeveral days, and are viſible from ſun-riſe to ſun-ſet. When the Parhelia diſappear, it ſometimes rains, or there falls ſnow in the form of oblong ſpiculæ. And Mariotte accounts for the appearance of Parhelia from an infinity of ſmall particles of ice floating in the air, which multiply the image of the ſun, either by refracting or breaking his rays, and thus making him appear where he is not; or by reflecting them, and ſerving as mirrors.

Moſt philoſophers have written upon Parhelia; as Ariſtotle, Pliny, Scheiner, Gaſſendi, Des Cartes, Huygens, Hevelius, De la Hire, Caſſini, Grey, Halley, Maraldi, Muſſchenbroek, &c. See Smith's Optics, book 1, chap. 11. Alſo Prieſtley's Hiſt. of Light &c, p. 613. And Muſſchenbroek's Introduction &c, vol. 2, p. 1038 quarto.

PARODICAL *Degrees*, in an equation, a term that has been ſometimes uſed to denote the ſeveral regular terms in a quadratic, cubic, biquadratic, &c, equation, when the indices of the powers aſcend or deſcend orderly in an arithmetical progreſſion. Thus, $x^3 + mx^2 + ux = p$ is a cubic equation where no term is wanting, but having all its Parodic Degrees; the indices of the terms regularly deſcending thus, 3, 2, 1, 0.

PART, *Aliquant*, *Aliquot*, *Circular Proportional*, *Similar*, &c. See the reſpective adjectives.

PART *of Fortune*, in Judicial Aſtrology, is the lunar horoſcope; or the point in which the moon is, at the time when the ſun is in the aſcending point of the eaſt.

The ſun in the aſcendant is ſuppoſed, according to this ſcience, to give life; and the moon diſpenſes the radical moiſture, and is one of the cauſes of fortune. In horoſcopes the Part of Fortune is repreſented by a circle divided by a croſs.

PARTICLE, the minute part of a body, or an aſſemblage of ſeveral of the atoms of which natural bodies are compoſed. Particle is ſometimes conſidered as ſynonymous with atom, and corpuſcle; and ſometimes they are diſtinguiſhed.

Particles are, as it were, the elements of bodies; by the various arrangement and texture of which, with the difference of the coheſion, &c, are conſtituted the ſeveral kinds of bodies, hard, ſoft, liquid, dry, heavy, light, &c. The ſmalleſt Particles or corpuſcles cohere with the ſtrongeſt attractions, and always compoſe larger Particles of weaker coheſion: and many of theſe, cohering, compoſe ſtill larger Particles, whoſe vigour is ſtill weaker; and ſo on for divers ſucceſſions, till the progreſſion end in the largeſt Particles, upon which the operations in chemiſtry, and the colours of natural bodies, depend; and which, by cohering, compoſe bodies of ſenſible magnitude.

PARTILE *Aſpect*, in Aſtrology, is when the planets are in the exact degree of any particular aſpect. In contradiſtinction to Platic Aſpect, or when they do not regard each other with thoſe very degrees. See ASPECT.

PARTY *Arches*, in Architecture, are arches built between ſeparate tenures, where the property is intermixed, and apartments over each other do not belong to the ſame eſtate.

PARTY *Walls*, are partitions of brick made between buildings in ſeparate occupations, for preventing the ſpread of fire. Theſe are made thicker than the external walls; and their thickneſs in London is regulated by act of parliament of the 14th of George the Third.

PASCAL (BLAISE), a reſpectable French mathematician and philoſopher, and one of the greateſt geniuſes and beſt writers that country has produced. He was born at Clermont in Auvergne, in the year 1623. His father, Stephen Paſcal, was preſident of the Court of Aids in his province: he was alſo a very learned man, an able mathematician, and a friend of Des Cartes. Having an extraordinary tenderneſs for this child, his only ſon, he quitted his office in his province, and ſettled at Paris in 1631, that he might be quite at leiſure to attend to his ſon's education, which he conducted himſelf, and young Paſcal never had any other maſter.

From his infancy Blaiſe gave proofs of a very extraordinary capacity. He was extremely inquiſitive; deſiring to know the reaſon of every thing; and when good reaſons were not given him, he would ſeek for better; nor would he ever yield his aſſent but upon ſuch as appeared to him well grounded. What is told of his manner of learning the mathematics, as well as the progreſs he quickly made in that ſcience, ſeems almoſt miraculous. His father, perceiving in him an extraordinary inclination to reaſoning, was afraid leſt the knowledge of the mathematics might hinder his learning the languages, ſo neceſſary as a foundation to all ſound learning. He therefore kept him as much as he could from all notions of geometry, locked up all his books of that kind, and refrained even from ſpeaking of it in his preſence. He could not however prevent his ſon from muſing on that ſcience; and one day in particular he ſurpriſed him at work with charcoal upon his chamber floor, and in the midſt of figures. The father aſked him what he was doing: I am ſearching, ſays Paſcal, for ſuch a thing; which was juſt the ſame as the 32d propoſition of the 1ſt book of Euclid. He aſked him then how he came to think of this: It was, ſays Blaiſe, becauſe I found out ſuch another thing; and ſo, going backward, and uſing the names of *bar* and *round*, he came at length to the definitions and axioms he had formed to himſelf. Does it not ſeem miraculous, that a boy ſhould work his way into the heart of a mathematical book, without ever having ſeen that or any other book upon the ſubject, or knowing any thing of the terms? Yet we are aſſured of the truth of this by his ſiſter, Madam Perier, and ſeveral other perſons, the credit of whoſe teſtimony cannot reaſonably be queſtioned.

From this time he had full liberty to indulge his genius in mathematical purſuits. He underſtood Euclid's Elements as ſoon as he caſt his eyes upon them. At 16 years of age he wrote a treatiſe on Conic Sections, which was accounted a great effort of genius; and therefore it is no wonder that Des Cartes, who had been in Holland a long time, upon reading it, ſhould chooſe to believe that M. Paſcal the father was the real author of it. At 19 he contrived an admirable arithmetical machine, which was eſteemed a very wonderful thing, and would have done credit as an invention to any man verſed in ſcience, and much more to ſuch a youth.

About this time his health became impaired, ſo that he was obliged to ſuſpend his labours for the ſpace of four years. After this, having ſeen Torricelli's experiment reſpecting a vacuum and the weight of the air, he turned his thoughts towards theſe objects, and undertook ſeveral new experiments, one of which was as follows: Having provided a glaſs tube, 46 feet in length, open at one end, and hermetically ſealed at the other, he filled it with red wine, that he might diſtinguiſh the liquor from the tube, and ſtopped up the orifice; then having inverted it, and placed it in a vertical poſition, with the lower end immerſed into a veſſel of water one foot deep, he opened the lower end, and the wine deſcended to the diſtance of about 32 feet from the ſurface of the veſſel, leaving a conſiderable vacuum at the upper part of the tube. He next inclined the tube gradually, till the upper end became only of 32 feet perpendicular height above the bottom, and he obſerved the liquor proportionally aſcend up to the top of the tube. He made alſo a great many experiments with ſiphons, ſyringes, bellows, and all kinds of tubes, making uſe of different liquors, ſuch as quickſilver, water, wine, oil, &c; and having publiſhed them in 1647, he diſperſed his work through all countries.

All theſe experiments however only aſcertained effects, without demonſtrating the cauſes. Paſcal knew that Torricelli conjectured that thoſe phenomena which he had obſerved were occaſioned by the weight of the air, though they had formerly been attributed to Nature's abhorrence of a vacuum; but if Torricelli's theory were true, he reaſoned that the liquor in the barometer tube ought to ſtand higher at the bottom of a hill, than at the top of it. In order therefore to diſcover the truth of this theory, he made an experiment at the top and bottom of a mountain in Auvergne, called *le Puy de Dome*, the reſult of which gave him reaſon to conclude that the air was indeed heavy. Of this experiment he publiſhed an account, and ſent copies of it to moſt of the learned men in Europe. He alſo renewed it at the top and bottom of ſeveral high towers, as thoſe of Notre Dame at Paris, St. Jaques de la Boucherie, &c; and always remarked the ſame difference in the weight of the air, at different elevations. This fully convinced him of the general preſſure of the atmoſphere; and from this diſcovery he drew many uſeful and important inferences. He compoſed alſo a large treatiſe, in which he fully explained this ſubject, and replied to all the objections that had been ſtarted againſt it. As he afterwards thought this work rather too prolix, and being fond of brevity and preciſion, he divided it into two ſmall treatiſes, one of which he intitled, A Diſſertation on the Equilibrium of Fluids; and the other, An Eſſay on the Weight of the Atmoſphere. Theſe labours procured Paſcal ſo much reputation, that the greateſt mathematicians and philoſophers of the age propoſed various queſtions to him, and conſulted him reſpecting ſuch difficulties as they could not reſolve. Upon one

of theſe occaſions he diſcovered the ſolution of a problem propoſed by Merſenne, which had baffled the penetration of all that had attempted it. This problem was to determine the curve deſcribed in the air by the nail of a coach-wheel, while the machine is in motion; which curve was thence called a roullette, but now commonly known by the name of cycloid. Paſcal offered a reward of 40 piſtoles to any one who ſhould give a ſatisfactory anſwer to it. No perſon having ſucceeded, he publiſhed his own at Paris; but as he began now to be diſguſted with the ſciences, he would not ſet his real name to it, but ſent it abroad under that of A. d'Ettonville.—This was the laſt work which he publiſhed in the mathematics; his infirmities, from a delicate conſtitution, though ſtill young, now increaſing ſo much, that he was under the neceſſity of renouncing ſevere ſtudy, and of living ſo recluſe, that he ſcarcely admitted any perſon to ſee him.—Another ſubject on which Paſcal wrote very ingeniouſly, and in which he has been ſpoken of as an inventor, was what has been called his Arithmetical Triangle, being a ſet of figurate numbers diſpoſed in that form. But ſuch a table of numbers, and many properties of them, had been treated of more than a century before, by Cardan, Stifelius, and other arithmetical writers.

After having thus laboured abundantly in mathematical and philoſophical diſquiſitions, he forſook thoſe ſtudies and all human learning at once, to devote himſelf to acts of devotion and penance. He was not 24 years of age, when the reading ſome pious books had put him upon taking this reſolution; and he became as great a devotee as any age has produced. He now gave himſelf up entirely to a ſtate of prayer and mortification; and he had always in his thoughts theſe great maxims of renouncing all pleaſure and all ſuperfluity; and this he practiſed with rigour even in his illneſſes, to which he was frequently ſubject, being of a very invalid habit of body.

Though Paſcal had thus abſtracted himſelf from the world, yet he could not forbear paying ſome attention to what was doing in it; and he even intereſted himſelf in the conteſt between the Jeſuits and the Janſeniſts. Taking the ſide of the latter, he wrote his *Lettres Provinciales*, publiſhed in 1656, under the name of *Louis de Montalte*, making the former the ſubject of ridicule. "Theſe letters, ſays Voltaire, may be conſidered as a model of eloquence and humour. The beſt comedies of Moliere have not more wit than the firſt part of theſe letters; and the ſublimity of the latter part of them, is equal to any thing in Boſſuet. It is true indeed that the whole book was built upon a falſe foundation; for the extravagant notions of a few Spaniſh and Flemiſh Jeſuits were artfully aſcribed to the whole ſociety. Many abſurdities might likewiſe have been diſcovered among the Dominican and Franciſcan caſuiſts; but this would not have anſwered the purpoſe; for the whole raillery was to be levelled only at the Jeſuits. Theſe letters were intended to prove, that the Jeſuits had formed a deſign to corrupt mankind; a deſign which no ſect or ſociety ever had, or can have." Voltaire calls Paſcal the firſt of their ſatiriſts; for Deſpréaux, ſays he, muſt be conſidered as only the ſecond. In another place, ſpeaking of this work of Paſcal, he ſays, that "Examples of all the various ſpecies of eloquence are to be found in it. Though it has now been written almoſt 100 years, yet not a ſingle word occurs in it, ſavouring of that viciſſitude to which living languages are ſo ſubject. Here then we are to fix the epoch when our language may be ſaid to have aſſumed a ſettled form. The biſhop of Lucon, ſon of the celebrated Buſſy, told me, that aſking one day the biſhop of Meaux what work he would covet moſt to be the author of, ſuppoſing his own performances ſet aſide, Boſſu replied, 'The Provincial Letters.'" Theſe letters have been tranſlated into all languages, and printed over and over again. Some have ſaid that there were decrees of formal condemnation againſt them; and alſo that Paſcal himſelf, in his laſt illneſs, deteſted them, and repented of having been a Janſeniſt: but both theſe particulars are falſe and without foundation. It was ſuppoſed that Father Daniel was the anonymous author of a piece againſt them, intitled *The Dialogues of Cleander and Eudoxus*.

Paſcal was but about 30 years of age when theſe letters were publiſhed; yet he was extremely infirm, and his diſorders increaſing ſoon after ſo much, that he conceived his end faſt approaching, he gave up all farther thoughts of literary compoſition. He reſolved to ſpend the remainder of his days in retirement and pious meditation; and with this view he broke off all his former connections, changed his habitation, and ſpoke to no one, not even to his own ſervants, and hardly ever even admitted them into his room. He made his own bed, fetched his dinner from the kitchen, and carried back the plates and diſhes in the evening; ſo that he employed his ſervants only to cook for him, to go to town, and to do ſuch other things as he could not abſolutely do himſelf. In his chamber nothing was to be ſeen but two or three chairs, a table, a bed, and a few books. It had no kind of ornament whatever; he had neither a carpet on the floor, nor curtains to his bed. But this did not prevent him from ſometimes receiving viſits; and when his friends appeared ſurpriſed to ſee him thus without furniture, he replied, that he had what was neceſſary, and that any thing elſe would be a ſuperfluity, unworthy of a wiſe man. He employed his time in prayer, and in reading the Scriptures; writing down ſuch thoughts as this exerciſe inſpired. Though his continual infirmities obliged him to uſe very delicate food, and though his ſervants employed the utmoſt care to provide only what was excellent, he never reliſhed what he ate, and ſeemed quite indifferent whether they brought him good or bad. His indifference in this reſpect was ſo great, that though his taſte was not vitiated, he forbad any ſauce or ragout to be made for him which might excite his appetite.

Though Paſcal had now given up intenſe ſtudy, and though he lived in the moſt temperate manner, his health continued to decline rapidly; and his diſorders had ſo enfeebled his organs, that his reaſon became in ſome meaſure affected. He always imagined that he ſaw a deep abyſs on one ſide of him, and he never would ſit down till a chair was placed there, to ſecure him from the danger which he apprehended. At another time he pretended that he had a kind of viſion or ecſtaſy; a memorandum of which he preſerved

during the remainder of his life on a bit of paper, put between the cloth and the lining of his coat, and which he always carried about him. After languiſhing for ſeveral years in this imbecile ſtate of body and mind, M. Paſcal died at Paris the 19th of Auguſt 1662, at 39 years of age.

In company, Paſcal was diſtinguiſhed by the amableneſs of his behaviour; by great modeſty; and by his eaſy, agreeable, and inſtructive converſation. He poſſeſſed a natural kind of eloquence, which was in a manner irreſiſtible. The arguments he employed for the moſt part produced the effect which he propoſed; and though his abilities intitled him to aſſume an air of ſuperiority, he never diſplayed that haughty and imperious tone which may often be obſerved in men of ſhining talents. The philoſophy of this extraordinary man conſiſted in renouncing all pleaſure, and every ſuperfluity. He not only denied himſelf the moſt common gratifications; but he took alſo without reluctance, and even with pleaſure, either as nouriſhment or as medicine, whatever was diſagreeable to the ſenſes; and he every day retrenched ſome part of his dreſs, food, or other things, which he conſidered as not abſolutely neceſſary. Towards the cloſe of his life, he employed himſelf wholly in devout and moral reflections, writing down thoſe which he deemed worthy of being preſerved. The firſt bit of paper he could find was employed for this purpoſe; and he commonly ſet down only a few words of each ſentence, as he wrote them merely for his own uſe. The ſcraps of paper upon which he had written theſe thoughts, were found after his death filed upon different pieces of ſtring, without any order or connection; and being copied exactly as they were written, they were afterward arranged and publiſhed, under the title of *Penſées, &c*, or *Thoughts upon Religion and other Subjects*; being parts of a work he had intended againſt atheiſts and infidels, which has been much admired. After his death appeared alſo two other little tracts; the one intitled, *The Equilibrium of Fluids*; and the other, *The Weight of the Maſs of Air*.

The works of Paſcal were collected in 5 volumes 8vo, and publiſhed at the Hague, and at Paris, in 1779. This edition of Paſcal's works may be conſidered as the firſt publiſhed; at leaſt the greater part of them were not before collected into one body, and ſome of them had remained only in manuſcript. For this collection, the public were indebted to the Abbé Boſſu, and Paſcal was deſerving of ſuch an editor. "This extraordinary man, ſays he, inherited from nature all the powers of genius. He was a mathematician of the firſt rank, a profound reaſoner, and a ſublime and elegant writer. If we reflect, that in a very ſhort life, oppreſſed by continual infirmities, he invented a curious arithmetical machine, the elements of the calculation of chances, and a method of reſolving various problems, reſpecting the cycloid; that he fixed in an irrevocable manner the wavering opinions of the learned concerning the weight of the air; that he wrote one of the completeſt works exiſting in the French language; and that in his *Thoughts* there are paſſages the depth and beauty of which are incomparable—we can hardly believe that a greater genius ever exiſted in any age or nation. All thoſe who had occaſion to frequent his company in the ordinary commerce of the world, acknowledged his ſuperiority; but it excited no envy againſt him, as he was never fond of ſhewing it. His converſation inſtructed, without making thoſe who heard him ſenſible of their own inferiority; and he was remarkably indulgent towards the faults of others. It may be eaſily ſeen by his Provincial Letters, and by ſome of his other works, that he was born with a great fund of humour, which his infirmities could never entirely deſtroy. In company, he readily indulged in that harmleſs and delicate raillery which never gives offence, and which greatly tends to enliven converſation; but its principal object was generally of a moral nature. For example, ridiculing thoſe authors who ſay, *My Book, my Commentary, my Hiſtory*, they would do better (added he) to ſay, *Our book, our Commentary, our Hiſtory*; ſince there is in them much more of other people's than their own."

The celebrated Baley too, ſpeaking of this great man, ſays, a hundred volumes of ſermons are not of ſo much avail as a ſimple account of the life of Paſcal. His humanity and his devotion mortified the libertines more than if they had been attacked by a dozen of miſſionaries. In ſhort, Bayle had ſo high an idea of this philoſopher, that he calls him *a paradox in the human ſpecies*. "When we conſider his character, ſays he, we are almoſt inclined to doubt whether he was born of a woman, like the man mentioned by Lucretius;

"*Ut vix humana videatur ſtirpe creatus.*"

PATE, in Fortification, a kind of platform, like what is called a Horſe-ſhoe; not always regular, but commonly oval, encompaſſed only with a parapet, and having nothing to flank it. It is uſually erected in marſhy grounds, to cover a gate of a town, or the like.

PATH *of the Vertex*, a term frequently uſed by Mr. Flamſteed, in his Doctrine of the Sphere, denoting a circle, deſcribed by any point of the earth's ſurface, as the earth turns round its axis.

This point is conſidered as vertical to the earth's centre; and is the ſame with what is called the vertex or zenith in the Ptolomaic projection.

The ſemidiameter of this Path of the vertex, is always equal to the complement of the latitude of the point or place that deſcribes it; that is, to the place's diſtance from the pole of the world.

PAVILION, in Architecture, is a kind of turret, or building uſually inſulated, and contained under a ſingle roof; ſometimes ſquare and ſometimes in form of a dome: thus called from the reſemblance of its roof to a tent.

PAVO, *Peacock*, a new conſtellation, in the ſouthern hemiſphere, added by the modern aſtronomers. It contains 14 ſtars.

PAUSE, or REST, in Muſic, a character of ſilence and reſt; called alſo by ſome a Mute Figure; becauſe it ſhews that ſome part or perſon is to be ſilent, while the others continue the ſong.

PECK, a meaſure or veſſel uſed in meaſuring grain, pulſe, and the like dry ſubſtances.

The ſtandard, or Winchester Peck, contains two gallons, or the 4th part of a buſhel.

PEDESTAL,

PEDESTAL, in Architecture, the loweſt part of an order of columns; being that which ſuſtains the column, and ſerves it as a foot to ſtand upon. It is a ſquare body or dye, with a cornice and baſe.

The proportions and ornaments of the Pedeſtal are different in the different orders. Vignola indeed, and moſt of the moderns, make the Pedeſtal, and its ornaments, in all the orders, one third of the height of the column, including the baſe and capital. But ſome deviate from this rule.

Perrault makes the proportions of the three conſtituent parts of Pedeſtals, the ſame in all the orders; viz, the baſe one fourth of the Pedeſtal; the cornice an eighth part; and the ſocle or plinth of the baſe, two thirds of the baſe itſelf. The height of the dye is what remains of the whole height of the Pedeſtal.

The *Tuſcan* PEDESTAL is the ſimpleſt and loweſt of all; from 3 to 5 modules high. It has only a plinth for its baſe, and an aſtragal crowned for its cornice.

The *Doric* PEDESTAL is made 4 or 5 modules in height, by the moderns; for no ancient columns, of this order, are found with any Pedeſtal, or even with any baſe.

The *Ionic* PEDESTAL is from 5 to 7 modules high.

The *Corinthian* PEDESTAL is the richeſt and moſt delicate of all, and is from 4 to 7 modules high.

The *Compoſite* PEDESTAL is of 6 or 7 modules in height.

Square PEDESTAL, is one whoſe breadth and height are equal.

Double PEDESTAL, is that which ſupports two columns, being broader than it is high.

Continued PEDESTAL, is that which ſupports a row of columns without any break or interruption.

PEDESTALS *of Statues*, are thoſe ſerving to ſupport figures or ſtatues.

PEDIMENT, in Architecture, a kind of low pinnacle; ſerving to crown porticos, or finiſh a frontiſpiece; and placed as an ornament over gates, doors, windows, niches, altars, &c; being uſually of a triangular form, but ſometimes an arch of a circle. Its height is various, but it is thought moſt beautiful when the height is one fifth of the length of its baſe.

PEDOMETER, or PODOMETER, foot-meaſurer, or way-wiſer; a mechanical inſtrument, in form of a watch, and conſiſting of various wheels and teeth; which, by means of a chain, or ſtring, faſtened to a man's foot, or to the wheel of a chariot, advance a notch each ſtep, or each revolution of the wheel: by which it numbers the paces or revolutions, and ſo the diſtance from one place to another.

PEDOMETER is alſo ſometimes uſed for the common ſurveying wheel, an inſtrument chiefly uſed in meaſuring roads; popularly called the way-wiſer. See PERAMBULATOR.

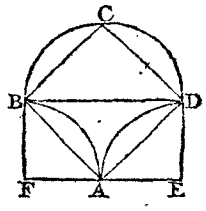
PEER, in Building. See PIER.

PEGASUS, the Horſe, a conſtellation of the northern hemiſphere, figured in the form of a flying horſe; being one of the 48 ancient conſtellations.

It is fabled, by the Greeks, to have been the offſpring of an amour between Neptune and the Gorgon Meduſa; and to have been that on which Bellerophon rode when he overcame the Chimera; and that flying from mount Helicon to heaven, he there became a conſtellation; having thrown his rider in the flight; and that the ſtroke of his hoof on the mount opened the ſacred fountain Hippocrene.

The ſtars in this conſtellation, in Ptolomy's catalogue, are 20, in Tycho's 19, in Hevelius's 38, and in the Britannic catalogue 89.

PELECOIDES, or *Hatchet-form*, in Geometry, a figure in form of a hatchet. As the figure ABCDA, contained under the ſemicircle BCD and the two quadrantal arcs AB and AD.



The area of the Pelecoides is equal to the ſquare AC, and this again is equal to the rectangle BE. It is equal to the ſquare, becauſe the two ſegments AB and AD, which it wants of the ſquare on the lower part, are compenſated by the two equal ſegments BC and CD, by which it exceeds on the upper part. And the ſquare is equal to the rectangle BE, becauſe the triangle ABD, which is half the ſquare, is alſo half the rectangle BE of the ſame baſe and height with it.

PELL (Dr. JOHN), an eminent Engliſh mathematician, deſcended from an ancient family in Lincolnſhire, was born at Southwick in Suſſex, March 1, 1610, where his father was miniſter. He received his grammar education at the free-ſchool at Stenning in that county. At the age of 13 he was ſent to Trinity College in Cambridge, being then as good a ſcholar as moſt maſters of arts in that univerſity; but though he was eminently ſkilled in the Greek and Hebrew languages, he never offered himſelf a candidate at the election of ſcholars or fellows of his college. His perſon was handſome; and being of a ſtrong conſtitution, uſing little or no recreations, he proſecuted his ſtudies with the more application and intenſeneſs.

In 1629 he drew up the "*Deſcription and Uſe of the Quadrant, written for the Uſe of a Friend,*" *in two books*; the original manuſcript of which is ſtill extant among his papers in the Royal Society. And the ſame year he held a correſpondence with Mr. Briggs on the ſubject of logarithms.

In 1630 he wrote, *Modus ſupputandi Ephemerides Aſtronomicas, &c, ad an.* 1630 *accommodatus*; and, *A Key to unlock the meaning of Johannes Trithemius, in his Diſcourſe of Steganography*: which Key he imparted to Mr. Samuel Hartlib and Mr. Jacob Homedæ. The ſame year he took the degree of Maſter of Arts at Cambridge. And the year following he was incorporated in the Univerſity of Oxford. June the 7th, he wrote *A Letter to Mr. Edmund Wingate on Logarithms*; and Oct. 5, 1631, *Commentationes in Coſmographiam Alſtedii.*

In 1632 he married Ithamaria, ſecond daughter of Mr. Henry Reginolles of London, by whom he had four ſons and four daughters.—March 6, 1634, he finiſhed his *Aſtronomical Hiſtory of Obſervations of Heavenly Motions and Appearances*; and April the 10th, his *Ecliptica Prognoſtica, or Foreknower of the Eclipſes, &c.*—In 1634 he tranſlated *The Everlaſting Tables of Heavenly*

Heavenly Motions, grounded upon the Obſervations of all Times, and agreeing with them all, by Philip Lanſberg, of Ghent in Flanders. And June the 12th, the ſame year, he committed to writing, *The Manner of Deducing his Aſtronomical Tables out of the Tables and Axioms of Philip Lanſberg.*—March the 9th, 1635, he wrote *A Letter of Remarks on Gellibrand's Mathematical Diſcourſe on the Variation of the Magnetic Needle.* And the 3d of June following, another on the ſame ſubject.

His eminence in mathematical knowledge was now ſo great, that he was thought worthy of a profeſſor's chair in that ſcience; and, upon the vacancy of one at Amſterdam in 1639, Sir William Boſwell, the Engliſh Reſident with the States General, uſed his intereſt, that he might ſucceed in that profeſſorſhip: it was not filled up however till 1643, when Pell was choſen to it; and he read with great applauſe public lectures upon Diophantus.—In 1644 he printed at Amſterdam, in two pages 4to, *A Refutation of Longomontanus's Diſcourſe, De Vera Circuli Menſura.*

In 1646, on the invitation of the Prince of Orange, he removed to the new college at Breda, as Profeſſor of Mathematics, with a ſalary of 1000 guilders a year.—His *Idea Matheſeos*, which he had addreſſed to Mr. Hartlib, who in 1639 had ſent it to Des Cartes and Merſenne, was printed 1650 at London, in 12mo, in Engliſh, with the title of *An Idea of Mathematics*, at the end of Mr. John Durie's Reformed Library-keeper. It is alſo printed by Mr. Hook, in his Philoſophical Collections, No. 5, p. 127; and is eſteemed our author's principal work.

In 1652 Pell returned to England: and in 1654 he was ſent by the protector Cromwell agent to the Proteſtant Cantons in Switzerland; where he continued till June 23, 1658, when he ſet out for England, where he arrived about the time of Cromwell's death. His negociations abroad gave afterwards a general ſatisfaction, as it appeared he had done no ſmall ſervice to the intereſt of king Charles the Second, and of the church of England; ſo that he was encouraged to enter into holy orders; and in the year 1661 he was inſtituted to the rectory of Fobbing in Eſſex, given him by the king. In December that year, he brought into the upper houſe of convocation the calendar reformed by him, aſſiſted by Sancroft, afterwards archbiſhop of Canterbury.—In 1673 he was preſented by Sheldon, biſhop of London, to the rectory of Laingdon in Eſſex; and, upon the promotion of that biſhop to the ſee of Canterbury ſoon after, became one of his domeſtic chaplains. He was then doctor of divinity, and expected to be made a dean; but his improvement in the philoſophical and mathematical ſciences was ſo much the bent of his genius, that he did not much purſue his private advantage. The truth is, he was a helpleſs man, as to worldly affairs, and his tenants and relations impoſed upon him, cozened him of the profits of his parſonage, and kept him ſo indigent, that he wanted neceſſaries, even ink and paper, to his dying day. He was for ſome time confined to the King's-bench priſon for debt; but, in March 1682, was invited by Dr. Whitler to live in the college of phyſicians. Here he continued till June following; when he was obliged, by his ill ſtate of health, to remove to the houſe of a grandchild of his in St. Margaret's Church-yard, Weſtminſter. But he died at the houſe of Mr. Cothorne, reader of the church of St. Giles's in the Fields, December the 12th, 1685, in the 74th year of his age, and was interred at the expence of Dr. Buſby, maſter of Weſtminſter ſchool, and Mr. Sharp, rector of St. Giles's, in the rector's vault under that church.—Dr. Pell publiſhed ſome other things not yet mentioned, a liſt of which is as follows: viz,

1. An Exercitation concerning Eaſter; 1644, in 4to.

2. A Table of 10,000 ſquare numbers, &c; 1672, folio.

3. An Inaugural Oration at his entering upon the Profeſſorſhip at Breda.

4. He made great alterations and additions to Rhonius's Algebra, printed at London 1668, 4to, under the title of, An Introduction to Algebra; tranſlated out of the High Dutch into Engliſh by Thomas Branker, much altered and augmented by D. P. (Dr. Pell). Alſo a Table of Odd Numbers, leſs than 100,000, ſhewing thoſe that are incompoſite, &c, ſupputated by the ſame Thomas Branker.

5. His Controverſy with Longomontanus concerning the Quadrature of the Circle; Amſterdam, 1646, 4to.

He likewiſe wrote a Demonſtration of the 2d and 10th books of Euclid; which piece was in MS. in the library of lord Brereton in Cheſhire: as alſo Archimedes's Arenarius, and the greateſt part of Diophantus's 6 books of Arithmetic; of which author he was preparing, Aug. 1644, a new edition, in which he intended to have corrected the tranſlation, and made new illuſtrations. He deſigned likewiſe to publiſh an edition of Apollonius, but laid it aſide, in May, 1645, at the deſire of Golius, who was engaged in an edition of that author from an Arabic manuſcript given him at Aleppo 18 years before. Letters of Dr. Pell to Sir Charles Cavendiſh, in the Royal Society.

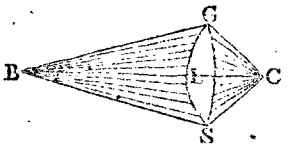
Some of his manuſcripts he left at Brereton in Cheſhire, where he reſided ſome years, being the ſeat of William lord Brereton, who had been his pupil at Breda. A great many others came into the hands of Dr. Buſby; which Mr. Hook was deſired to uſe his endeavours to obtain for the Society. But they continued buried under duſt, and mixed with the papers and pamphlets of Dr. Buſby, in four large boxes, till 1755; when Dr. Birch, ſecretary to the Royal Society, procured them for that body, from the truſtees of Dr. Buſby. The collection contains not only Pell's mathematical Papers, letters to him, and copies of thoſe from him, &c, but alſo ſeveral manuſcripts of Walter Warner, the mathematician and philoſopher, who lived in the reigns of James the Firſt and Charles the Firſt.

Dr. Pell invented the method of ranging the ſeveral ſteps of an algebraical calculus, in a proper order, in ſo many diſtinct lines, with the number affixed to each ſtep, and a ſhort deſcription of the operation or proceſs in the line. He alſo invented the character ÷ for diviſion, ⊛ for involution, and ⊞ for evolution.

PENCIL *of Rays*, in Optics, is a double cone, or pyramid, of rays, joined together at the baſe; as

BGSC:

BGSC: the one cone having its vertex in ſome point of the object at B, and the cryſtalline humour, or the glaſs GLS for its baſe; and the other having its baſe on the ſame glaſs, or cryſtalline, but its vertex in the point of convergence, as at C.



PENDULUM, in Mechanics, any heavy body, ſo ſuſpended as that it may ſwing backwards and forwards, about ſome fixed point, by the force of gravity.

Theſe alternate aſcents and deſcents of the Pendulum, are called its Oſcillations, or Vibrations; each complete oſcillation being the deſcent from the higheſt point on one ſide, down to the loweſt point of the arch, and ſo on up to the higheſt point on the other ſide. The point round which the Pendulum moves, or vibrates, is called its Centre of Motion, or Point of Suſpenſion; and a right line drawn through the centre of motion, parallel to the horizon, and perpendicular to the plane in which the Pendulum moves, is called the Axis of Oſcillation. There is alſo a certain point within every Pendulum, into which, if all the matter that compoſes the Pendulum were collected, or condenſed as into a point, the times in which the vibrations would be performed, would not be altered by ſuch condenſation; and this point is called Centre of Oſcillation. The length of the Pendulum is always eſtimated by the diſtance of this point below the centre of motion; being uſually near the bottom of the Pendulum; but in a cylinder, or any other uniform priſm or rod, it is at the diſtance of one third from the bottom, or two-thirds from and below the centre of motion.

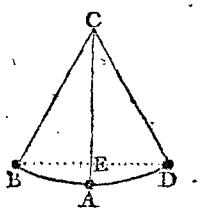
The length of a Pendulum, ſo meaſured to its centre of oſcillation, that it will perform each vibration in a ſecond of time, thence called the ſecond's Pendulum, has, in the latitude of London, been generally taken at $39\frac{2}{10}$ or $39\frac{1}{5}$ inches; but by ſome very ingenious and accurate experiments, the late celebrated Mr. George Graham found the true length to be $39\frac{1393}{1000}$ inches, or $39\frac{1}{8}$ inches very nearly.

The length of the Pendulum vibrating ſeconds at Paris, was found by Varin, Des Hays, De Glos, and Godin, to be $440\frac{5}{6}$ lines; by Picard $440\frac{1}{2}$ lines; and by Mairan $440\frac{7}{12}$ lines.

Galileo was the firſt who made uſe of a heavy body annexed to a thread, and ſuſpended by it, for meaſuring time, in his experiments and obſervations. But according to Sturmius, it was Riccioli who firſt obſerved the iſochroniſm of Pendulums, and made uſe of them in meaſuring time. After him, Tycho, Langrene, Wendeline, Merſenne, Kircher, and others, obſerved the ſame thing; though, it is ſaid, without any intimation of what had been done by Riccioli. But it was the celebrated Huygens who firſt demonſtrated the principles and properties of Pendulums, and probably the firſt who applied them to clocks. He demonſtrated, that if the centre of motion were perfectly fixed and immoveable, and all manner of friction, and reſiſtance of the air, &c, removed, then a Pendulum, once ſet in motion, would for ever continue to vibrate without any decreaſe of motion, and that all its vibrations would be perfectly iſochronal, or performed in the ſame time. Hence the Pendulum has univerſally been conſidered as the beſt chronometer or meaſurer of time. And as all Pendulums of the ſame length perform their vibrations in the ſame time, without regard to their different weights, it has been ſuggeſted, by means of them, to eſtabliſh an univerſal ſtandard for all countries. On this principle Mouton, canon of Lyons, has a treatiſe, De Menſura poſteris tranſmittenda; and ſeveral others ſince, as Whitehurſt, &c. See *Univerſal* MEASURE.

Pendulums are either ſimple or compound, and each of theſe may be conſidered either in theory, or as in practical mechanics among artiſans.

A Simple PENDULUM, in Theory, conſiſts of a ſingle weight, as A, conſidered as a point, and an inflexible right line AC, ſuppoſed void of gravity or weight, and ſuſpended from a fixed point or centre C, about which it moves.



A Compound PENDULUM, in Theory, is a Pendulum conſiſting of ſeveral weights moveable about one common centre of motion, but connected together ſo as to retain the ſame diſtance both from one another, and from the centre about which they vibrate.

The Doctrine and Laws of PENDULUMS.—1. A Pendulum raiſed to B, through the arc of the circle AB, will fall, and riſe again, through an equal arc, to a point equally high, as D; and thence will fall to A, and again riſe to B; and thus continue riſing and falling perpetually. For it is the ſame thing, whether the body fall down the inſide of the curve BAD, by the force of gravity, or be retained in it by the action of the ſtring; for they will both have the ſame effect; and it is otherwiſe known, from the oblique deſcents of bodies, that the body will deſcend and aſcend along the curve in the manner above deſcribed.

Experience alſo confirms this theory, in any finite number of oſcillations. But if they be ſuppoſed infinitely continued, a difference will ariſe. For the reſiſtance of the air, and the friction and rigidity of the ſtring about the centre C, will take off part of the force acquired in falling; whence it happens that it will not riſe preciſely to the ſame point from whence it fell.

Thus, the aſcent continually diminiſhing the oſcillation, this will be at laſt ſtopped, and the Pendulum will hang at reſt in its natural direction, which is perpendicular to the horizon.

Now as to the real time of oſcillation in a circular arc BAD: it is demonſtrated by mathematicians, that if $p = 3{\cdot}1416$, denote the circumference of a circle whoſe diameter is 1; $g = 16\frac{1}{12}$ feet or 193 inches, the ſpace a heavy body falls in the firſt ſecond of time; and $r =$ CA the length of the Pendulum; alſo $a =$ AE the height of the arch of vibration; then the time

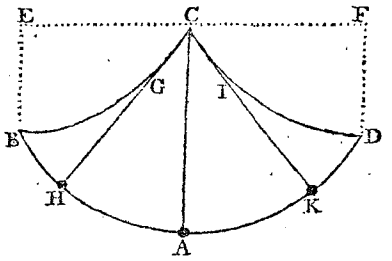
time of each oſcillation in the arc BAD will be equal to $p\sqrt{\frac{r}{2g}} \times$ into the infinite ſeries

$$1 + \frac{1^2 a}{2^2 d} + \frac{1^2 . 3^2 a^2}{2^2 . 4^2 d^2} + \frac{1^2 . 3^2 . 5^2 a^3}{2^2 . 4^2 . 6^2 d^3} \text{ \&c,}$$

where $d = 2r$ is the diameter of the arc deſcribed, or twice the length of the Pendulum.

And here, when the arc is a ſmall one, as in the caſe of the vibrating Pendulum of a clock, all the terms of this ſeries after the 2d may be omitted, on account of their ſmallneſs; and then the time of a whole vibration will be nearly equal to $p\sqrt{\frac{r}{2g}} \times (1 + \frac{a}{8r})$. So that the times of vibration of a Pendulum in different ſmall arcs of the ſame circle, are as $8r + a$, or 8 times the radius, added to the verſed ſine of the ſemiarc.

And farther, if D denote the number of degrees in the ſemiarc AB, whoſe verſed ſine is a, then the quantity laſt mentioned, for the time of a whole vibration, is changed to $p\sqrt{\frac{r}{2g}} \times (1 + \frac{D^2}{52524})$. And therefore the times of vibration in different ſmall arcs, are as $52524 + D^2$, or as the number 52524 added to the ſquare of the number of degrees in the ſemiarc AB. See my Conic Sections and Select Exerciſes, p. 190.



2. Let CB be a ſemicycloid, having its baſe EC parallel to the horizon, and its vertex B downwards; and let CD be the other half of the cycloid, in a ſimilar poſition to the former. Suppoſe a Pendulum ſtring, of the ſame length with the curve of each ſemicycloid BC, or CD, having its end fixed in C, and the thread applied all the way cloſe to the cycloidal curve BC, and conſequently the body or Pendulum weight coinciding with the point B. If now the body be let go from B, it will deſcend by its own gravity, and in deſcending it will unwind the ſtring from off the arch BC, as at the poſition CGH; and the ball G will deſcribe a ſemicycloid BHA, equal and ſimilar to BGC, when it has arrived at the loweſt point A; after which, it will continue its motion, and aſcend, by another equal and ſimilar ſemicycloid AKD, to the ſame height D, as it fell from at B, the ſtring now wrapping itſelf upon the other arch CID. From D it will deſcend again, and paſs along the whole cycloid DAB, to the point B; and thus perform continual ſucceſſive oſcillations between B and D, in the curve of a cycloid; as it before oſcillated in the curve of a circle, in the former caſe.

This contrivance to make the Pendulum oſcillate in the curve of a cycloid, is the invention of the celebrated Huygens, to make the Pendulum perform all its vibrations in equal times, whether the arch, or extent of the vibration be great or ſmall; which is not the caſe in a circle, where the larger arcs take a longer time to run through them, than the ſmaller ones do, as is well known both from theory and practice.

The chief properties of the cycloidal Pendulum then, as demonſtrated by Huygens, are the following. 1ſt, That the time of an oſcillation in all arcs, whether larger or ſmaller, is always the ſame quantity, viz, whether the body begin to deſcend from the point B, and deſcribe the ſemiarch BA; or that it begins at H, and deſcribes the arch HA; or that it ſets out from any other point; as it will ſtill deſcend to the loweſt point A in exactly the ſame time. And it is farther proved, that the time of a whole vibration through any double arc BAD, or HAK, &c, is in proportion to the time in which a heavy body will freely fall, by the force of gravity, through a ſpace equal to $\frac{1}{2}$AC, half the length of the Pendulum, as the circumference of a circle is to its diameter. So that, if $g = 16\frac{1}{12}$ feet denote the ſpace a heavy body falls in the firſt ſecond of time, $p = 3.1416$ the circumference of a circle whoſe diameter is 1, and $r =$ AC the length of the Pendulum; then, becauſe, by the nature of deſcents by gravity, $\sqrt{g} : \sqrt{\frac{1}{2}r} :: 1'' : \sqrt{\frac{r}{2g}}$ that is the time in which a body will fall through $\frac{1}{2}r$, or half the length of the Pendulum; therefore, by the above proportion, as $1 : p :: \sqrt{\frac{r}{2g}} : p\sqrt{\frac{r}{2g}}$, which is the time of an entire oſcillation in the cycloid.

And this concluſion is abundantly confirmed by experience. For example, if we conſider the time of a vibration as 1 ſecond, to find the length of the Pendulum that will ſo oſcillate in 1 ſecond; this will give the equation $p\sqrt{\frac{r}{2g}} = 1$; which reduced, gives $r = \frac{2g}{p^2} = \frac{386}{3.1416^2}$ inches $= 39.11$ or $39\frac{1}{8}$ inches, for the length of the ſecond's Pendulum; which the beſt experiments ſhew to be about $39\frac{1}{8}$ inches.

3. Hence alſo, we have a method of determining, from the experimented length of a Pendulum, the ſpace a heavy body will fall perpendicularly through in a given time; for, ſince $p\sqrt{\frac{r}{2g}} = 1$, therefore, by reduction, $g = \frac{1}{2}p^2 r$ is the ſpace a body will fall through in the firſt ſecond of time, when r denotes the length of the ſecond's Pendulum; and as conſtant experience ſhews that this length is nearly $39\frac{1}{8}$ inches, in the latitude of London, in this caſe g or $\frac{1}{2}p^2 r$ becomes $\frac{1}{2} \times 3.1416^2 \times 39\frac{1}{8} = 193.07$ inches $= 16\frac{1}{12}$ feet, very nearly, for the ſpace a body will fall in the firſt ſecond of time, in the latitude of London: a fact which has been abundantly confirmed by experiments made there. And in the ſame manner, Mr. Huygens found the ſame ſpace fallen through at Paris, to be 15 French feet.

The whole doctrine of Pendulums, oſcillating between two ſemicycloids, both in theory and practice, was

was delivered by that author, in his Horologium Oſcillatorium, five Demonſtrationes de Motu Pendulorum. And every thing that regards the motion of Pendulums has ſince been demonſtrated in different ways, and particularly by Newton, who has given an admirable theory on the ſubject, in his Principia, where he has extended to epicycloids the properties demonſtrated by Huygens of the cycloids.

4. As the cycloid may be conſidered as coinciding, in A, with any ſmall arc of a circle deſcribed from the centre C, paſſing through A, where it is known the two curves have the ſame radius and curvature; therefore the time in the ſmall arc of ſuch a circle, will be nearly equal to the time in the cycloid; ſo that the times in very ſmall circular arcs are equal, becauſe theſe ſmall arcs may be conſidered as portions of the cycloid, as well as of the circle. And this is one great reaſon why the Pendulums of clocks are made to oſcillate in as ſmall arcs as poſſible, viz, that their oſcillations may be the nearer to a conſtant equality.

This may alſo be deduced from a compariſon of the times of vibration in the circle, and in the cycloid, as laid down in the foregoing articles. It has there been ſhewn, that the times of vibration in the circle and cycloid are thus, viz,

$$\text{time in the circle nearly } p\sqrt{\frac{r}{2g}} \times \left(1 + \frac{a}{8r}\right),$$

$$\text{time in the cycloidal arc } p\sqrt{\frac{r}{2g}};$$

where it is evident, that the former always exceeds the latter in the ratio of $1 + \frac{a}{8r}$ to 1; but this ratio always approaches nearer to an equality, as the arc, or as its verſed ſine a, is ſmaller; till at length, when it is very ſmall, the term $\frac{a}{8r}$ may be omitted, and then the times of vibration become both the ſame quantity, viz $p\sqrt{\frac{r}{2g}}$.

Farther, by the ſame compariſon, it appears, that the time loſt in each ſecond, or in each vibration of the ſecond's Pendulum, by vibrating in a circle, inſtead of a cycloid, is $\frac{a}{8r}$, or $\frac{D^2}{52524}$; and conſequently the time loſt in a whole day of 24 hours, is $\frac{5}{6}D^2$ nearly. In like manner, the ſeconds loſt per day by vibrating in the arc of Δ degrees, is $\frac{5}{6}\Delta^2$. Therefore if the Pendulum keep true time in one of theſe arcs, the ſeconds loſt or gained per day, by vibrating in the other, will be $\frac{5}{6}(D^2 - \Delta^2)$. So, for example, if a Pendulum meaſure true time in an arc of 3 degrees, on each ſide of the loweſt point, it will loſe $11\frac{2}{3}$ ſeconds a day by vibrating 4 degrees; and $26\frac{1}{4}$ ſeconds a day by vibrating 5 degrees; and ſo on.

5. The action of gravity is leſs in thoſe parts of the earth where the oſcillations of the ſame Pendulum are ſlower, and greater where theſe are ſwifter; for the time of oſcillation is reciprocally proportional to $\sqrt{g}$. And it being found by experiment, that the oſcillations of the ſame Pendulum are ſlower near the equator, than in places farther from it; it follows that the force of gravity is leſs there; and conſequently the parts about the equator are higher or farther from the centre, than the other parts; and the ſhape of the earth is not a true ſphere, but ſomewhat like an oblate ſpheroid, flatted at the poles, and raiſed gradually towards the equator. And hence alſo the times of the vibration of the ſame Pendulum, in different latitudes, afford a method of determining the true figure of the earth, and the proportion between its axis and the equatorial diameter.

Thus, M. Richer found by an experiment made in the iſland Cayenna, about 4 degrees from the equator, where a Pendulum 3 feet $8\frac{5}{6}$ lines long, which at Paris vibrated ſeconds, required to be ſhortened a line and a quarter to make it vibrate ſeconds. And many other obſervations have confirmed the ſame principle. See Newton's Principia, lib. 3, prop. 20. By comparing the different obſervations of the French aſtronomers, Newton apprehends that 2 lines may be conſidered as the length a ſeconds Pendulum ought to be decreaſed at the equator.

From ſome obſervations made by Mr. Campbell, in 1731, in Black-river, in Jamaica, 18° north latitude, it is collected, that if the length of a ſimple Pendulum that ſwings ſeconds in London, be 39·126 Engliſh inches, the length of one at the equator would be 39·00, and at the poles 39·206. Philoſ. Tranſ. numb. 432; or Abr. vol. 8, part 1, pa. 238.

And hence Mr. Emerſon has computed the following Table, ſhewing the length of a Pendulum that ſwings ſeconds at every 5th degree of latitude, as alſo the length of the degree of latitude there, in Engliſh miles.

Degrees of Lat.	Length of Pendulum.	Length of the Degree.
	inches.	miles.
0	39·027	68·723
5	39·029	68·730
10	39·032	68·750
15	39·036	68·783
20	39·044	68·830
25	39·057	68·882
30	39·070	68·950
35	39·084	69·020
40	39·097	69·097
45	39·111	69·176
50	39·126	69·256
55	39·142	69·330
60	39·158	69·401
65	39·168	69·467
70	39·177	69·522
75	39·185	69·568
80	39·191	69·601
85	39·195	69·620
90	39·197	69·628

6. If two Pendulums vibrate in ſimilar arcs, the times of vibration are in the ſub-duplicate ratio of their lengths. And the lengths of Pendulums vibrating in ſimilar arcs, are in the duplicate ratio of the times

of a vibration directly; or in the reciprocal duplicate ratio of the number of oſcillations made in any one and the ſame time. For, the time of vibration t being as $p\sqrt{\frac{r}{2g}}$, where p and g are conſtant or given, therefore t is as $\sqrt{r}$, and r as t^2. Hence therefore the length of a half-ſecond Pendulum will be $\frac{1}{4}r$ or $\frac{39\frac{1}{8}}{4} = 9{\cdot}781$ inches; and the length of the quarter-ſecond Pendulum will be $\frac{1}{16}r = \frac{39\frac{1}{8}}{16} = 2{\cdot}445$ inches; and ſo of others.

7. The foregoing laws, &c, of the motion of Pendulums, cannot ſtrictly hold good, unleſs the thread that ſuſtains the ball be void of weight, and the gravity of the whole ball be collected into a point. In practice therefore, a very fine thread, and a ſmall ball, but of a very heavy matter, are to be uſed. But a thick thread, and a bulky ball, diſturb the motion very much; for in that caſe, the ſimple Pendulum becomes a compound one; it being much the ſame thing, as if ſeveral weights were applied to the ſame inflexible rod in ſeveral places.

8. M. Krafft in the new Peterſburgh Memoirs, vols 6 and 7, has given the reſult of many experiments upon Pendulums, made in different parts of Ruſſia, with deductions from them, from whence he derives this theorem: If x be the length of a Pendulum that ſwings ſeconds in any given latitude l, and in a temperature of 10 degrees of Reaumur's thermometer, then will the length of that Pendulum, for that latitude, be thus expreſſed, viz,

$x = (439{\cdot}178 + 2{\cdot}321 \times \text{ſin.}^2 l)$ lines of a French foot.

And this expreſſion agrees very nearly, not only with all the experiments made on the Pendulum in Ruſſia, but alſo, with thoſe of Mr. Graham, and thoſe of Mr. Lyons in 79° 50′ north latitude, where he found its length to be 441·38 lines. See OBLATENESS.

Simple PENDULUM, in Mechanics, an expreſſion commonly uſed among artiſts, to diſtinguiſh ſuch Pendulums as have no proviſion for correcting the effects of heat and cold, from thoſe that have ſuch proviſion. Alſo Simple Pendulum, and Detached Pendulum, are terms ſometimes uſed to denote ſuch Pendulums as are not connected with any clock, or clock-work.

Compound PENDULUM, in Mechanics, is a Pendulum whoſe rod is compoſed of two or more wires or bars of metal. Theſe, by undergoing different degrees of expanſion and contraction, when expoſed to the ſame heat or cold, have the difference of expanſion or contraction made to act in ſuch manner as to preſerve conſtantly the ſame diſtance between the point of ſuſpenſion, and centre of oſcillation, although expoſed to very different and various degrees of heat or cold. There are a great variety of conſtructions for this purpoſe; but they may be all reduced to the Gridiron, the Mercurial, and the Lever Pendulum.

It may be juſt obſerved by the way, that the vulgar method of remedying the inconvenience ariſing from the extenſion and contraction of the rods of common Pendulums, is by applying the bob, or ſmall ball, with a ſcrew, at the lower end; by which means the Pendulum is at any time made longer or ſhorter, as the ball is ſcrewed downwards or upwards, and thus the time of its vibration is kept continually the ſame.

The *Gridiron* PENDULUM was the invention of Mr. John Harriſon, a very ingenious artiſt, and celebrated for his invention of the watch for finding the difference of longitude at ſea, about the year 1725; and of ſeveral other time-keepers and watches ſince that time; for all which he received the parliamentary reward of between 20 and 30 thouſand pounds. It conſiſts of 5 rods of ſteel, and 4 of braſs, placed in an alternate order, the middle rod being of ſteel, by which the Pendulum ball is ſuſpended; theſe rods of braſs and ſteel, thus placed in an alternate order, and ſo connected with each other at their ends, that while the expanſion of the ſteel rods has a tendency to lengthen the Pendulum, the expanſion of the braſs rods, acting upwards, tends to ſhorten it. And thus, when the lengths of the braſs and ſteel rods are duly proportioned, their expanſions and contractions will exactly balance and correct each other, and ſo preſerve the Pendulum invariably of the ſame length. The ſimplicity of this ingenious contrivance is much in its favour; and the difficulty of adjuſtment ſeems the only objection to it.

Mr. Harriſon in his firſt machine for meaſuring time at ſea, applied this combination of wires of braſs and ſteel, to prevent any alterations by heat or cold; and in the machines or clocks he has made for this purpoſe, a like method of guarding againſt the irregularities ariſing from this cauſe is uſed.

The *Mercurial* PENDULUM was the invention of the ingenious Mr. Graham, in conſequence of ſeveral experiments relating to the materials of which Pendulums might be formed, in 1715. Its rod is made of braſs, and branched towards its lower end, ſo as as to embrace a cylindric glaſs veſſel 13 or 14 inches long, and about 2 inches diameter; which being filled about 12 inches deep with mercury, forms the weight or ball of the Pendulum. If upon trial the expanſion of the rod be found too great for that of the mercury, more mercury muſt be poured into the veſſel: if the expanſion of the mercury exceeds that of the rod, ſo as to occaſion the clock to go faſt with heat, ſome mercury muſt be taken out of the veſſel, ſo as to ſhorten the column. And thus may the expanſion and contraction of the quickſilver in the glaſs be made exactly to balance the expanſion and contraction of the Pendulum rod, ſo as to preſerve the diſtance of the centre of oſcillation from the point of ſuſpenſion invariably the ſame.

Mr. Graham made a clock of this ſort, and compared it with one of the beſt of the common ſort, for 3 years together; when he found the errors of his but about one-eighth part of thoſe of the latter. Philoſ. Tranſ. numb. 392.

The *Lever* PENDULUM. From all that appears concerning this conſtruction of a Pendulum, we are inclined to believe that the idea of making the difference of the expanſion of different metals operate by means of a lever, originated with Mr. Graham, who in the year 1737 conſtructed a Pendulum, having its rod compoſed of one bar of ſteel between two of braſs, which acted upon the ſhort end of a lever, to the other end of which, the ball or weight of the Pendulum was ſuſpended.

This

This Pendulum however was, upon trial, found to move by jerks; and therefore laid aſide by the inventor, to make way for the mercurial Pendulum, juſt mentioned.

Mr. Short informs us in the Philoſ. Tranſ. vol. 47, art. 88, that a Mr. Frötheringham, a quaker in Lincolnſhire, cauſed a Pendulum of this kind to be made: it conſiſted of two bars, one of braſs, and the other of ſteel, faſtened together by ſcrews, with levers to raiſe or let down the bulb; above which theſe levers were placed. M. Caſſini too, in the Hiſtory of the Royal Academy of Sciences at Paris, for 1741, deſcribes two ſorts of Pendulums for clocks, compounded of bars of braſs and ſteel, and in which he applies a lever to raiſe or let down the bulb of the Pendulum, by the expanſion or contraction of the bar of braſs.

Mr. John Ellicott alſo, in the year 1738, conſtructed a Pendulum on the ſame principle, but differing from Mr. Graham's in many particulars. The rod of Mr. Ellicott's Pendulum was compoſed of two bars only; the one of braſs, and the other of ſteel. It had two levers, each ſuſtaining its half of the ball or weight; with a ſpring under the lower part of the ball to relieve the levers from a conſiderable part of its weight, and ſo to render their motion more ſmooth and eaſy. The one lever in Mr. Graham's conſtruction was above the ball: whereas both the levers in Mr. Ellicott's were within the ball; and each lever had an adjuſting ſcrew, to lengthen or ſhorten the lever, ſo as to render the adjuſtment the more perfect. See the Philoſ. Tranſ. vol. 47, p. 479; where Mr. Ellicott's methods of conſtruction are deſcribed, and illuſtrated by figures.

Notwithſtanding the great ingenuity diſplayed by theſe very eminent artiſts on this conſtruction, it muſt farther be obſerved, in the hiſtory of improvements of this nature, that Mr. Cumming, another eminent artiſt, has given, in his Eſſays on the Principles of Clock and Watch-work, Lond. 1766, an ample deſcription, with plates, of a conſtruction of a Pendulum with levers, in which it ſeems he has united the properties of Mr. Graham's and Mr. Ellicott's, without being liable to any of the defects of either. The rod of this Pendulum is compoſed of one flat bar of braſs, and two of ſteel; he uſes three levers within the ball of the Pendulum; and, among many other ingenious contrivances, for the more accurate adjuſting of this Pendulum to mean time, it is provided with a ſmall ball and ſcrew below the principal ball or weight, one entire revolution of which on its ſcrew will only alter the rate of the clock's going one ſecond per day; and its circumference is divided into 30, one of which diviſions will therefore alter its rate of going one ſecond in a month.

Pendulum *Clock*, is a clock having its motion regulated by the vibration of a Pendulum.

It is controverted between Galileo and Huygens, which of the two firſt applied the Pendulum to a clock. For the pretenſions of each, ſee Clock.

After Huygens had diſcovered, that the vibration made in arcs of a cycloid, however unequal they might be in extent, were all equal in time; he ſoon perceived, that a Pendulum applied to a clock, ſo as to make it deſcribe arcs of a cycloid, would rectify the otherwiſe unavoidable irregularities of the motion of the clock; ſince, though the ſeveral cauſes of thoſe irregularities ſhould occaſion the Pendulum to make greater or ſmaller vibrations, yet, by virtue of the cycloid, it would ſtill make them perfectly equal in point of time; and the motion of the clock governed by it, would therefore be preſerved perfectly equable. But the difficulty was, how to make the Pendulum deſcribe arcs of a cycloid; for naturally the Pendulum, being tied to a fixed point, can only deſcribe circular arcs about it.

Here M. Huygens contrived to fix the iron rod or wire, which bears the ball or weight, at the top to a ſilken thread, placed between two cycloidal cheeks, or two little arcs of a cycloid, made of metal. Hence the motion of vibration, applying ſucceſſively from one of thoſe arcs to the other, the thread, which is extremely flexible, eaſily aſſumes the figure of them, and by that means cauſes the ball or weight at the bottom to deſcribe a juſt cycloidal arc.

This is doubtleſs one of the moſt ingenious and uſeful inventions many ages have produced: by means of which it has been aſſerted there have been clocks that would not vary a ſingle ſecond in ſeveral days: and the ſame invention alſo gave riſe to the whole doctrine of involute and evolute curves, with the radius and degree of curvature, &c.

It is true, the Pendulum is ſtill liable to its irregularities, how minute ſoever they may be. The ſilken thread by which it was ſuſpended, ſhortens in moiſt weather, and lengthens in dry; by which means the length of the whole Pendulum, and conſequently the times of the vibrations, are ſomewhat varied.

To obviate this inconvenience, M. De la Hire, inſtead of a ſilken thread, uſed a little fine ſpring; which was not indeed ſubject to ſhorten and lengthen, from thoſe cauſes; yet he found it grew ſtiffer in cold weather, and then made its vibrations faſter than in warm; to which alſo we may add its expanſion and contraction by heat and cold. He therefore had recourſe to a ſtiff wire or rod, firm from one end to the other. Indeed by this means he renounced the advantages of the cycloid; but he found, as he ſays, by experience, that the vibrations in circular arcs are performed in times as equal, provided they be not of too great extent, as thoſe in cycloids. But the experiments of Sir Jonas Moore, and others, have demonſtrated the contrary.

The ordinary cauſes of the irregularities of Pendulums, Dr. Derham aſcribes to the alterations in the gravity and temperature of the air, which increaſe and diminiſh the weight of the ball, and by that means make the vibrations greater and leſs; an acceſſion of weight in the ball being found by experiment to accelerate the motion of the Pendulum; for a weight of 6 pounds added to the ball, Dr. Derham found made his clock gain 13 ſeconds every day.

A general remedy againſt the inconveniences of Pendulums, is to make them long, the ball heavy, and to vibrate but in ſmall arcs. Theſe are the uſual means employed in England; the cycloidal cheeks being generally neglected. See the foregoing article.

Pendulum clocks reſting againſt the ſame rail have been found to influence each other's motion. See the Philoſ. Tranſ. numb. 453, ſect. 5 and 6, where Mr. Ellicott has given a curious and exact account of this phenomenon.

PENDULUM *Royal*, a name uſed among us for a clock, whoſe Pendulum ſwings ſeconds, and goes 8 days without winding up; ſhewing the hour, minute, and ſecond. The numbers in ſuch a piece are thus calculated. Firſt caſt up the ſeconds in 12 hours, which are the beats in one turn of the great wheel; and they will be found to be $43200 = 12 \times 60 \times 60$. The ſwing wheel muſt be 30, to ſwing 60 ſeconds in one of its revolutions; now let the half of 43200, viz 21600, be divided by 30, and the quotient will be 720, which muſt be ſeparated into quotients. The firſt of theſe muſt be 12, for the great wheel, which moves round once in 12 hours. Now 720 divided by 12, gives 60, which may alſo be conveniently broken into two quotients, as 10 and 6, or 12 and 5, or 8 and $7\frac{1}{2}$; which laſt is moſt convenient: and if the pinions be all taken 8, the work will ſtand thus:

8)	96 (	12
8)	64 (	8
8)	60 (	$7\frac{1}{2}$
		30

According to this computation, the great wheel will go round once in 12 hours, to ſhew the hour; the next wheel once in an hour, to ſhew the minutes; and the ſwing-wheel once in a minute, to ſhew the ſeconds. See CLOCK-WORK.

Balliſtic PENDULUM. See BALLISTIC *Pendulum*.

Level PENDULUM. See LEVEL.

PENDULUM *Watch*. See WATCH.

PENETRABILITY, capability of being penetrated. See IMPENETRABILITY.

PENETRATION, the act by which one thing enters another, or takes up the place already poſſeſſed by another.

The ſchoolmen define Penetration the co-exiſtence of two or more bodies, ſo that one is preſent, or has its extenſion in the ſame place as the other.

Moſt philoſophers hold the penetration of bodies abſurd, i. e. that two bodies ſhould be at the ſame time in the ſame place; and accordingly impenetrability is laid down as one of the eſſential properties of matter.

What is popularly called Penetration, only amounts to the matter of one body's being admitted into the vacuity of another. Such is the Penetration of water through the ſubſtance of gold.

PENINSULA, is a portion or extent of land which is almoſt ſurrounded with water, being joined to the continent only by an iſthmus, or narrow neck. Such is Africa, the greateſt Peninſula in the world, which is joined to Aſia, by the neck at the end of the Red Sea; ſuch alſo is Peloponneſus, or the Morea, joined to Greece: and Jutland, &c. Peninſula is the ſame with what is otherwiſe called Cherſoneſus.

PENNY, formerly a piece of ſilver coin, but now an imaginary ſum, equal to two copper coins called a halfpenny.

The Penny was the firſt ſilver coin ſtruck in England by our Saxon anceſtors, being the 240th part of their pound, and its true weight was about $22\frac{1}{2}$ grains Troy.

In Etheldred's time, the Penny was the 20th part of the Troy ounce, and equal in weight to our three pence; which value it retained till the time of Edward the Third.

Till the time of King Edward the Firſt, the Penny was ſtruck with a croſs ſo deeply ſunk in it, that it might, on occaſion, be eaſily broken, and parted into two halves, thence called Halfpennies; or into four, thence called Fourthings, or Farthings. But that Prince coined it without the croſs; inſtead of which he ſtruck round Halfpence and Farthings. Though there are ſaid to be inſtances of ſuch round Halfpence having been made in the reign of Henry the Firſt, if not alſo in that of the two Williams.

Edward the Firſt alſo reduced the weight of the Penny to a ſtandard; ordering that it ſhould weigh 32 grains of wheat, taken out of the middle of the ear. This Penny was called the Penny Sterling; and 20 of them were to weigh an ounce; whence the Penny became a weight as well as a coin.

By the 9th of Edward the Third, it was diminiſhed to the 26th part of the Troy ounce; by the 2d of Henry the Sixth it was the 32d part; by the 5th of Edward the Fourth, it became the 40th, and alſo by the 36th of Henry the Eighth, and afterwards, the 45th; but by the 2d of Elizabeth, 60 Pence were coined out of the ounce, and during her reign 62, which laſt proportion is ſtill obſerved in our times.

The Penny Sterling is now diſuſed as a coin; and ſcarce ſubſiſts, but as a money of account, containing two copper Halfpence, or the 12th part of a ſhilling, or the 240th part of a pound.

The French Penny, or Denier, is of two kinds; the Paris Penny, called Denier Pariſis; and the Penny of Tours, called Denier Tournois.

The Dutch Penny, called Pennink, or Pening, is a real money, worth about one-fifth more than the French Penny Tournois. The Pennink is alſo uſed as a money of account, in keeping books by pounds, florins, and patards; 12 Penninks make the patard, and 20 patards the florin.

At Hamburg, Nuremberg, &c, the Penny or Pfennig of account is equal to the French Penny Tournois. Of theſe, 8 make the krieuk; and 60 the florin of thoſe cities; alſo 90 the French crown, or 4s 6d ſterling.

PENNY-*Weight*, a Troy weight, being the 20th part of an ounce, containing 24 grains; each grain weighing a grain of wheat gathered out of the middle of the ear, well dried. The name took its riſe from its being actually the weight of one of our ancient ſilver Pennies. See the foregoing article.

PENTAGON, in Geometry, a plane figure conſiſting of five angles, and conſequently five ſides alſo. If the angles be all equal, it is a regular Pentagon.

It is a remarkable property of the Pentagon, that its ſide is equal in power to the ſides of a hexagon and a decagon inſcribed in the ſame circle; that is, the ſquare of the ſide of the Pentagon, is equal to both the ſquares taken together of the ſides of the other two figures; and conſequently thoſe three ſides will conſti-

tute a right-angled triangle. Euclid, book 13, prop. 10.

Pappus has alſo demonſtrated, that 12 regular Pentagons contain more than 20 triangles inſcribed in the ſame circle; lib. 5, prop. 45.

The dodecahedron, which is the fourth regular body or ſolid, is contained under 12 equal and regular Pentagons.

To find the Area of a Regular PENTAGON. Multiply the ſquare of its ſide by 1·7204774, or by $\frac{5}{4}$ of the tangent of 54°, or by $\frac{5}{4}\sqrt{1 + \frac{2}{5}\sqrt{5}}$. Hence if s denote the ſide of the Pentagon, its area will be $1{\cdot}7204774s^2 = \frac{5}{4}s^2\sqrt{1 + \frac{2}{5}\sqrt{5}} = \frac{5}{4}s^2 \times$ tang. 54°.

PENTAGRAPH, otherwiſe called a Parallelogram, a mathematical inſtrument for copying deſigns, prints, plans, &c, in any proportion.

The common Pentagraph (Plate xix, fig. 2) conſiſts of four rulers or bars, of metal or wood, two of them from 15 to 18 inches long, the other two half that length. At the ends, and in the middle, of the long rulers, as alſo at the ends of the ſhorter ones, are holes upon the exact fixing of which the perfection of the inſtrument chiefly depends. Thoſe in the middle of the long rulers are to be at the ſame diſtance from thoſe at the end of the long ones, and thoſe of the ſhort ones; ſo that, when put together, they may always make a parallelogram.

The inſtrument is fitted together for uſe, by ſeveral little pieces, particularly a little pillar, number 1, having at one end a nut and ſcrew, joining the two long rulers together; and at the other end a ſmall knot for the inſtrument to ſlide on. The piece numb. 2 is a rivet with a ſcrew and nut by which each ſhort ruler is faſtened to the middle of each long one. The piece numb. 3 is a pillar, one end of which, being hollowed into a ſcrew, has a nut fitted to it; and at the other end is a worm to ſcrew into the table; when the inſtrument is to be uſed, it joins the ends of the two ſhort rulers. The piece numb. 4 is a pen, or pencil, or portcrayon, ſcrewed into a little pillar. Laſtly, the piece numb. 5 is a braſs point, moderately blunt, ſcrewed likewiſe into a little pillar.

Uſe of the PENTAGRAPH.—1. To copy a deſign in the ſame ſize or ſcale as the original. Screw the worm numb. 3 into the table; lay a paper under the pencil numb. 4, and the deſign under the point numb. 5. This done, conducting the point over the ſeveral lines and parts of the deſign, the pencil will draw or repeat the ſame on the paper.

2. When the deſign is to be reduced — ex. gr. to half the ſcale; the worm muſt be placed at the end of the long ruler numb. 4, and the paper and pencil in the middle. In this ſituation conduct the braſs point over the ſeveral lines of the deſign, as before; and the pencil at the ſame time will draw its copy in the proportion required; the pencil here only moving half the lengths that the point moves.

3. On the contrary, when the deſign is to be enlarged to a double ſize; the braſs point, with the deſign, muſt be placed in the middle at numb. 3, the pencil and paper at the end of the long ruler, and the worm at the other end.

4. To reduce or enlarge in other proportions, there are holes drilled at equal diſtances on each ruler; viz, all along the ſhort ones, and half way of the long ones, for placing the braſs point, pencil, and worm, in a right line in them; i. e. if the piece carrying the point be put in the third hole, the other two pieces muſt be put each in its third hole; &c.

PENTANGLE, a plane figure of five angles, or the ſame as the PENTAGON.

PENUMBRA, in Aſtronomy, a faint or partial ſhade, in an eclipſe, obſerved between the perfect ſhadow, and the full light.

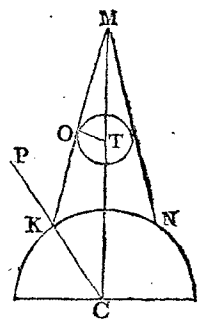
The Penumbra ariſes from the magnitude of the ſun's body: were he only a luminous point, the ſhadow would be all perfect; but by reaſon of the diameter of the ſun it happens, that a place which is not illuminated by the whole body of the ſun, does yet receive rays from ſome part of it.

Thus, ſuppoſe S the ſun, and T the moon, and the ſhadow of the latter projected on a plane, as GH (Plate xix, fig. 3). The true proper ſhadow of T, viz GH, will be encompaſſed with an imperfect ſhadow, or Penumbra, HL and GE, each portion of which is illuminated by an entire hemiſphere of the ſun.

The degree of light or ſhade of the Penumbra, will be more or leſs in different parts, as thoſe parts lie open to the rays of a greater or leſs part of the ſun's body; thus from L to H, and from E to G, the light continually diminiſhes; and in the confines of G and H, the Penumbra is darkeſt, and becomes loſt and confounded with the total ſhade: as near E and L it is thin and confounded with the total light.

A Penumbra muſt be found in all eclipſes, whether of the ſun, the moon, or the other planets, primary or ſecondary; but it is moſt conſiderable with us in eclipſes of the ſun; which is the caſe here referred to.

The Penumbra extends infinitely in length, and grows ſtill wider and wider; two rays drawn from the two extremities of the earth's diameter, and which proceed always diverging, form its two edges; all that infinite diverging ſpace, included between lines paſſing through E and L, is the Penumbra, except the cone of the ſhadow in the middle of it.



To determine how much of the ſurface of the earth can be involved in the Penumbra, let the apparent ſemidiameter of the ſun be ſuppoſed the greateſt, or about 16′ 20″, which is when the earth is in her perihelion; alſo let the moon be in her apogee, and therefore at her greateſt diſtance from the earth, or about 64 of the earth's ſemidiameters. Let KNC be the earth, T the moon, and MKN the Penumbra, involving the part of the earth from K to N, which it is required to find. Here then are given the angle KMC = 16′ 20″, TC = 64, KC = 1, and OT = $\frac{1}{40}$ of KC. Hence, in the right-angled triangle OTM, as ſin. OMT : radius :: OT : TM = 210½OT = 58KC nearly. Therefore MC = MT + TC = 58 + 64 = 122 ſemidiameters of the earth. Then, in the triangle KMC, there are given

KC =

KC = 4, and MC = 122, alſo the angle KMC = 16′ 20″, to find the angle C; thus, as

KC : MC :: ſin. ∠ KMC : ſin. ∠ MKP =	35°	25′	35″;
from this take the ∠ KMC - - -	0	16	20,
leaves the ∠ C - - - - -	35	9	11,
the double of which is the arc KN	70	18	22,

or nearly a ſpace of 4866 miles in diameter.

PERAMBULATOR, an inſtrument for meaſuring diſtances; called alſo Pedometer, Waywiſer, and Surveying Wheel.

This wheel is contrived to meaſure out a pole, or 16½ feet, in making two revolutions; conſequently its circumference is 8¼ feet, and its diameter 2·626 feet, or 2 feet 5½ inches and $\frac{1}{1000}$ parts, very nearly. It is either driven forward by two handles, by a perſon walking; or is drawn by a coach wheel, &c, to which it is attached by a pole. It contains various movements, by wheels, or clock-work, with indices on its face, which is like that of a clock, to point out the diſtance paſſed over, in miles, furlongs, poles, yards, &c.

Its advantages are its readineſs and expedition; being very uſeful for meaſuring roads, and great diſtances on level ground. See the fig. Plate xvii, fig. 6.

PERCH, in Surveying, a ſquare meaſure, being the 40th part of a rood, or the 160th part of an acre; that is, the ſquare of a pole or rod, of the length of 5½ yards, or 16½ feet.

PERCH is by ſome alſo made to mean a meaſure of length; being the ſame as the rod or pole of 5½ yards or 16½ feet long. But it is better, for preventing confuſion, to diſtinguiſh them.

PERCUSSION, in Phyſics, the impreſſion a body makes in falling or ſtriking upon another; or the ſhock or colliſion of two bodies, which meeting alter each other's motion.

Percuſſion is either Direct or Oblique. It is alſo either of Elaſtic or Nonelaſtic bodies, which have each their different laws. It is true, we know of no bodies in nature that are either perfectly elaſtic or the contrary; but all partaking that property in different degrees; even the hardeſt and the ſofteſt being not entirely diveſted of it. But, for the ſake of perſpicuity, it is uſual, and proper, to treat of theſe two ſeparately and apart.

Direct PERCUSSION is that in which the impulſe is made in the direction of a line perpendicular at the place of impact, and which alſo paſſes through the common centre of gravity of the two ſtriking bodies. As is the caſe in two ſpheres, when the line of the direction of the ſtroke paſſes through the centres of both ſpheres; for then the ſame line, joining their centres, paſſes perpendicularly through the point of impact. And

Oblique PERCUSSION, is that in which the impulſe is made in the direction of a line that does not paſs through the common centre of gravity of the ſtriking bodies; whether that line of direction is perpendicular to the place of impact, or not.

The force of Percuſſion is the ſame as the momentum, or quantity of motion, and is repreſented by the product ariſing from the maſs or quantity of matter moved, multiplied by the velocity of its motion; and that without any regard to the time or duration of action; for its action is conſidered totally independent of time, or but as for an inſtant, or an infinitely ſmall time.

This conſideration will enable us to reſolve a queſtion that has been greatly canvaſſed among philoſophers and mathematicians, viz, what is the relation between the force of Percuſſion and mere preſſure or weight? For we hence infer, that the former force is infinitely, or incomparably, greater than the latter. For, let M denote any maſs, body, or weight, having no motion or velocity, but ſimply its preſſure; then will that preſſure or force be denoted by M itſelf, if it be conſidered as acting for ſome certain finite aſſignable time; but, conſidered as a force of Percuſſion, that is, as acting but for an infinitely ſmall time, its velocity being 0, or nothing, its percuſſive force will be 0 × M, that is 0, or nothing; and is therefore leſs than any the ſmalleſt percuſſive force whatever. Again, let us conſider the two forces, viz, of Percuſſion and preſſure, with reſpect to the effects they produce: Now the intenſity of any force is very well meaſured and eſtimated by the effect it produces in a given time: But the effect of the preſſure M, in 0 time, or an infinitely ſmall time, is nothing at all; that is, it will not, in an infinitely ſmall time, produce, for example, any motion, either in itſelf, or in any other body: its intenſity therefore, as its effect, is infinitely leſs than any the ſmalleſt force of Percuſſion. It is true, indeed, that we ſee motion and other conſiderable effects produced by mere preſſure, and to counteract which it will require the oppoſition of ſome conſiderable percuſſive force: but then it muſt be obſerved, that the former has been an infinitely longer time than the latter in producing its effect; and it is no wonder in mathematics that an infinite number of infinitely ſmall quantities makes up a finite one. It has therefore only been for want of conſidering the circumſtance of *time*, that any queſtion could have ariſen on this head. Hence the two forces are related to each other, only as a ſurface is to a ſolid or body: by the motion of the ſurface through an infinite number of points, or through a finite right line, a ſolid or body is generated: and by the action of the preſſure for an infinite number of moments, or for ſome finite time, a quantity equal to a given percuſſive force is generated: but the ſurface itſelf is infinitely leſs than any ſolid, and the preſſure infinitely leſs than any percuſſive force. This point may be eaſily illuſtrated by ſome familiar inſtances, which prove at leaſt the enormous diſproportion between the two forces, if not alſo their abſolute incomparability. And firſt, the blow of a ſmall hammer, upon the head of a nail, will drive the nail into a board; when it is hard to conceive any weight ſo great as will produce a like effect, i. e. that will ſink the nail as far into the board, at leaſt unleſs it is left to act for a very conſiderable time: and even after the greateſt weight has been laid as a preſſure on the head of the nail, and has ſunk it as far as it can as to ſenſe, by remaining for a long time there without producing any farther ſenſible effect; let the weight be removed from the head of the nail, and inſtead of it, let it be ſtruck a ſmall blow with a hammer, and the nail will immediately ſink farther into the wood. Again, it is alſo well known, that a ſhip-carpenter, with a blow of his mallet, will drive a wedge in below the greateſt ſhip whatever, lying aground, and ſo overcome her weight, and lift her up. Laſtly, let us conſider a man with a club to ſtrike a ſmall ball, upwards or in

any other direction; it is evident that the ball will acquire a certain determinate velocity by the blow, ſuppoſe that of 10 feet per ſecond, or minute, or any other time whatever: now it is a law, univerſally allowed in the communication of motion, that when different bodies are ſtruck with equal forces, the velocities communicated are reciprocally as the weights of the bodies that are ſtruck; that is, that a double body, or weight, will acquire half the velocity from an equal blow; a body 10 times as great, one 10th of the velocity; a body 100 times as great, the 100th part of the velocity; a body a million times as great, the millionth part of the velocity; and ſo on without end: from whence it follows, that there is no body or weight, how great ſoever, but will acquire ſome finite degree of velocity, and be overcome, by any given ſmall finite blow, or Percuſſion.

It appears that Des Cartes, firſt of any, had ſome ideas of the laws of Percuſſion; though it muſt be acknowledged, in ſome caſes perhaps wide of the truth. The firſt who gave the true laws of motion in non-elaſtic bodies, was Doctor Wallis, in the Philoſ. Tranſ. numb. 43, where he alſo ſhews the true cauſe of reflections in other bodies, and proves that they proceed from their elaſticity. Not long after, the celebrated Sir Chriſtopher Wren and Mr. Huygens imparted to the Royal Society the laws that are obſerved by perfectly elaſtic bodies, and gave exactly the ſame conſtruction, though each was ignorant of what the other had done. And all thoſe laws, thus publiſhed in the Philoſ. Tranſ. without demonſtration, were afterwards demonſtrated by Dr. Keill, in his Philoſ. Lect. in 1700; and they have ſince been followed by a multitude of other authors.

In Percuſſion, we diſtinguiſh at leaſt three ſeveral ſorts of bodies; the perfectly hard, the perfectly ſoft, and the perfectly elaſtic. The two former are conſidered as utterly void of elaſticity; having no force to ſeparate them, or throw them off from each other again, after colliſion; and therefore either remaining at reſt, or elſe proceeding uniformly forward together as one body or maſs of matter.

The laws of Percuſſion therefore to be conſidered, are of two kinds: thoſe for elaſtic, and thoſe for non-elaſtic bodies.

The one only general principle, for determining the motions of bodies from Percuſſion, and which belongs equally to both the ſorts of bodies, i. e. both the elaſtic and nonelaſtic, is this: viz, that there exiſts in the bodies the ſame momentum, or quantity of motion, eſtimated in any one and the ſame direction, both before the ſtroke and after it. And this principle is the immediate reſult of the third law of nature or motion, that reaction is equal to action, and in a contrary direction; from whence it happens, that whatever motion is communicated to one body by the action of another, exactly the ſame motion doth this latter loſe in the ſame direction, or exactly the ſame does the former communicate to the latter in the contrary direction.

From this general principle too it reſults, that no alteration takes place in the common centre of gravity of bodies by their actions upon one another; but that the ſaid common centre of gravity perſeveres in the ſame ſtate, whether of reſt or of uniform motion, both before and after the ſhock of the bodies.

Now, from either of theſe two laws, viz, that of the preſervation of the ſame quantity of motion, in one and the ſame direction, and that of the preſervation of the ſame ſtate of the centre of gravity, both before and after the ſhock, all the circumſtances of the motions of both the kinds of bodies after colliſion may be made out; in conjunction with their own peculiar and ſeparate conſtitutions, namely, that of the one ſort being elaſtic, and the other nonelaſtic.

The effects of theſe different conſtitutions, here alluded to, are theſe; that nonelaſtic bodies, on their ſhock, will adhere together, and either remain at reſt, or elſe move together as one maſs with a common velocity; or if elaſtic, they will ſeparate after the ſhock with the very ſame relative velocity with which they met and ſhocked. The former of theſe conſequences is evident, viz, that nonelaſtic bodies keep together as one maſs after they meet; becauſe there exiſts no power to ſeparate them; and without a cauſe there can be no effect. And the latter conſequence reſults immediately from the very definition and eſſence of elaſticity itſelf, being a power always equal to the force of compreſſion, or ſhock; and which reſtoring force therefore, acting the contrary way, will generate the ſame relative velocity between the bodies, or the ſame quantity of matter, as before the ſhock, and the ſame motion alſo of their common centre of gravity.

To apply now the general principle to the determination of the motions of bodies after their ſhock; let B and b be any two bodies, and V and v their reſpective velocities, eſtimated in the direction AD; which quantities V and v will be both poſitive if the bodies both move towards D, but one of them as v will be negative if the body b move towards A, and v will be $= 0$ if the body b be at reſt. Hence then BV is the momentum of B towards D, and bv is the momentum of b towards D, whoſe ſum is $BV + bv$, which is the whole quantity of motion in the direction AD, and which momentum muſt alſo be preſerved after the ſhock.

Now if the bodies have no elaſticity, they will move together as one maſs $B + b$ after they meet, with ſome common velocity, which call y, in the direction AD; therefore the momentum in that direction after the ſhock, being the product of the maſs and velocity, will be $(B + b) \times y$. But the momenta, in the ſame direction, before and after the impact, are equal, that is $BV + bv = (B + b)\,y$; from which equation any one of the quantities may be determined when the reſt are given. So, if we would find the common velocity after the ſtroke, it will be $y = \frac{BV + bv}{B + b}$, equal to the ſum of the momenta divided by the ſum of the bodies; which is alſo equal to the velocity of the common centre of gravity of the two bodies, both before and after the colliſion. The ſigns of the terms, in this value of y, will be all poſitive, as above,

above, when the bodies move both the ſame way AD; but one term bv muſt be made negative when the motion of b is the contrary way; and that term will be abſent or nothing, when b is at reſt, before the ſhock.

Again, for the caſe of elaſtic bodies, which will ſeparate after the ſtroke, with certain velocities, x and z, viz, x the velocity of B, and z the velocity of b after the colliſion, both eſtimated in the direction AD, which quantities will be either poſitive, or negative, or nothing, according to the circumſtances of the maſſes B and b, with thoſe of their celerities before the ſtroke. Hence then Bx and bz are the ſeparate momenta after the ſhock, and $Bx + bz$ their ſum, which muſt be equal to the ſum $BV + bv$ in the ſame direction before the ſtroke: alſo $z - x$ is the relative velocity with which the bodies ſeparate after the blow, and which muſt be equal to $V - v$ the ſame with which they meet; or, which is the ſame thing, that $V + x = v + z$; that is, the ſum of the two velocities of the one body, is equal to the ſum of the velocities of the other, taken before and after the ſtroke; which is another notable theorem. Hence then, for determining the two unknown quantities x and z, there are theſe two equations,

$$\text{viz, } BV + bv = Bx + bz,$$
$$\text{and } V - v = z - x;$$
$$\text{or } V + x = v + z;$$

the reſolution of which equations gives thoſe two velocities as below,

$$\text{viz, } x = \frac{2bv + (B - b)V}{B + b},$$
$$\text{and } z = \frac{2BV - (B - b)v}{B + b}.$$

From theſe general values of the velocities, which are to be underſtood in the direction AD, any particular caſes may eaſily be drawn. As, if the two bodies B and b be equal, then $B - b = 0$, and $B + b = 2B$, and the two velocities in that caſe become, after impulſe, $x = v$, and $z = V$, the very ſame as they were before, but changed to the contrary bodies, i. e. the bodies have taken each other's velocity that it had before, and with the ſame ſign alſo. So that, if the equal bodies were before both moving the ſame way, or towards D, they will do the ſame after, but with interchanged velocities. But if they before moved contrary ways, B towards D, and b towards A, they will rebound contrary ways, B back towards A, and b towards D, each with the other's velocity. And, laſtly, if one body, as b, were at reſt before the ſtroke, then the other B will be at reſt after it, and b will go on with the motion that B had before. And thus may any other particular caſes be deduced from the firſt general values of x and z.

We may now conclude this article with ſome remarks on theſe motions, and the miſtakes of ſome authors concerning them. And firſt, we obſerve this ſtriking difference between the motions that are communicated by elaſtic and by nonelaſtic bodies, viz, that a nonelaſtic body, by ſtriking, communicates to the body it ſtrikes, exactly its whole momentum; as is evident. But the ſtroke of an elaſtic body may either communicate its whole motion to the body it ſtrikes, or it may communicate only a part of it, or it may even communicate more than it had. For, if the ſtriking body remain at reſt after the ſtroke, it has juſt loſt all its motion, and therefore has communicated all it had; but if it ſtill move forward in the ſame direction, it has ſtill ſome motion left in that direction, and therefore has only communicated a part of what motion it had; and if the ſtriking body rebound back, and move in the contrary direction, the other body has received not only the whole of the motion that the firſt had, but alſo as much more as the firſt has acquired in the contrary direction.

It has been denied by ſome authors, and in their Encyclopédie, that the ſame quantity of motion remains after the ſhock, as before it; and hence they ſeize an opportunity to reprehend the Carteſians for making that aſſertion, which they do, not only with reſpect to the caſe of two bodies, but alſo of all the bodies in the whole univerſe. And yet nothing is more true, if the motion be conſidered as eſtimated always in one and the ſame direction, eſteeming that as negative, which is in the contrary or oppoſite direction. For it is a general law of nature, that no motion, nor force, can be generated, nor deſtroyed, nor changed, but by ſome cauſe which muſt produce an equal quantity in the oppoſite direction. And this being the caſe in one body, or two bodies, it muſt neceſſarily be the caſe in all bodies, and in the whole ſolar ſyſtem, ſince all bodies act upon one another. And hence alſo it is manifeſt, that the common centre of gravity of the whole ſolar ſyſtem muſt always preſerve its original condition, whether it be of reſt or of uniform motion; ſince the ſtate of that centre is not changed by the mutual actions of bodies upon one another, any more than their quantity of motion, in one and the ſame direction.

What may have led authors into the miſtake above alluded to, which they bring no proof of, ſeems to be the diſcovery of M. Huygens, that the ſums of the two products are equal, both before and after the ſhock, that are made by multiplying each body by the ſquare of its velocity, viz, that $BV^2 + bv^2 = Bx^2 + bz^2$, where V and v are the velocities before the ſhock, and x and z the velocities after it. Such an expreſſion, namely the product of the maſs by the ſquare of the velocity, is called the vis viva, or living force; and hence it has been inferred that the whole vis viva before the ſhock, or $BV^2 + bv^2$, is equal to that after the ſtroke, or $Bx^2 + bz^2$; which is indeed very true, as will be ſhewn preſently. But when they hence infer, both that therefore the forces of bodies in motion are as the ſquares of the velocities, and that there is not the ſame quantity of motion between the two ſtriking bodies, both before and after the ſhock, they are groſsly miſtaken, and thereby ſhew that they are ignorant of the true derivation of the equation $BV^2 + bv^2 = Bx^2 + bz^2$. For this equation is only a conſequence of the very principle above laid down, and which is not acceded to by thoſe authors, viz, that the quantity of motion is the ſame before and after the ſhock, or that $BV + bv = Bx + bz$, the truth of which laſt equation they deny, becauſe they think the former one is true, never dreaming that they may be both true, and much leſs that the one is a conſequence of the other, and derived from it; which however is now found to be the caſe, as is proved in this manner:

It has been ſhewn that the ſum of the two momenta,

in

in the same direction, before and after the stroke, are equal, or that $BV + bv = Bx + bz$; and also that the sum of the two velocities of the one body, is equal to the sum of those of the other, or that $V + x = v + z$; and it is now proposed to shew that from these two equations there results the third equation $BV^2 + bv^2 = Bx^2 + bz^2$, or the equation of the living forces.

Now because $BV + bx = Bx + bz$, by transposition it is $BV - Bz = bz - bv$; which shews that the difference between the two momenta of the one body, before and after the stroke, is equal to the difference between those of the other body; which is another notable theorem. But now, to derive the equation of the vis viva, set down the two foregoing equations, and multiply them together, so shall the products give the said equation required; thus

Mult. $BV - Bx = bz - bv$, the equat. of the momenta, by $V + x = z + v$, the equat. of the velocities,

produc. $BV^2 - Bv^2 = bz^2 - bv^2$,

or $BV^2 + bv^2 = Bx^2 + bz^2$,

the very equation of the vis viva required. Which was to be proved.

When the elasticity of the bodies is not perfect, but only partially so, as is the case with all the bodies we know of, the determination of the motions after collision may be determined in a similar manner. See Keill's Lect. Philos. lect. 14, theor. 29, at the end. And for the geometrical determinations after impact, see the article Collision.

Centre of Percussion, is the point in which the shock or impulse of a body which strikes another is the greatest that it can be. See Centre.

The Centre of Percussion is the same as the centre of oscillation, when the striking body moves round a fixed axis. See Oscillation.

But if all the parts of the striking body move with a parallel motion, and with the same velocity, then the Centre of Percussion is the same as the centre of gravity.

PERFECT Number, is one that is equal to the sum of all its aliquot parts, when added together. Eucl. lib. 7, def. 22. As the number 6, which is $= 1 + 2 + 3$, the sum of all its aliquot parts; also 28, for $28 = 1 + 2 + 4 + 7 + 14$, the sum of all its aliquot parts.

It is proved by Euclid, in the last prop. of book the 9th, that if the common geometrical series of numbers 1, 2, 4, 8, 16, 32, &c, be continued to such a number of terms, as that the sum of the said series of terms shall be a prime number, then the product of this sum by the last term of the series will be a perfect number.

This same rule may be otherwise expressed thus: If n denote the number of terms in the given series 1, 2, 4, 8, &c; then it is well known that the sum of all the terms of the series is $2^n - 1$, and it is evident that the last term is 2^{n-1}: consequently the rule becomes thus, viz, $2^{n-1} \times 2^n - 1 =$ a perfect number, whenever $2^n - 1$ is a prime number.

Now the sums of one, two, three, four, &c, terms of the series 1, 2, 4, 8, &c, form the series 1, 3, 7, 15, 31, &c; so that the number will be found perfect whenever the corresponding term of this series is a prime, as 1, 3, 7, 31, &c. Whence the table of perfect numbers may be found and exhibited as follows; where the 1st column shews the number of terms, or the value of n; the 2d column is the last term of the series 1, 2, 4, 8, &c, and is expressed by 2^{n-1}; the 3d column contains the corresponding sums of the said series, or the values of the quantity $2^n - 1$; which numbers in this 3d column are easily constructed by adding always the last number in this column to the next following number in the 2d column: and lastly, the 4th column shews the correspondent Perfect Numbers, or the values of $2^{n-1} \times 2^n - 1$, the product of the numbers in the 2d and 3d columns, when $2^n - 1$, or the number in the 3d column, is a prime number; the products in the other cases being omitted, as not Perfect Numbers.

Values of n	Values of 2^{n-1}	Values of $2^n - 1$	Perf. Numbers, or $2^{n-1} \times (2^n - 1)$
1	1	1	1
2	2	3	6
3	4	7	28
4	8	15	.
5	16	31	496
6	32	63	.
7	64	127	8128

Hence the first four Perfect Numbers are found to be 6, 28, 496, 8128; and thus the table might be continued to find others, but the trouble would be very great, for want of a general method to distinguish which numbers are primes, as the case requires. Several learned mathematicians have endeavoured to facilitate this business, but hitherto with only a small degree of perfection. After the foregoing four Perfect Numbers, there is a long interval before any more occur. The first eight are as follow, with the factors and products which produce them:

The first Perfect Numbers.	Their values.
6	$= (2^2 - 1)\, 2$
28	$= (2^3 - 1)\, 2^2$
496	$= (2^5 - 1)\, 2^4$
8128	$= (2^7 - 1)\, 2^6$
33550336	$= (2^{13} - 1)\, 2^{12}$
8589869056	$= (2^{17} - 1)\, 2^{16}$
13743869328	$= (2^{19} - 1)\, 2^{18}$
2305843008139952128	$= (2^{31} - 1)\, 2^{30}$

See several considerable tracts on the subject of Perfect Numbers in the Memoirs of the Petersburgh Academy, vol. 2 of the new vols, and in several other volumes.

PERIÆCI. See Perioeci.

PERIGÆUM, or Perigee, is that point of the orbit of the sun or moon, which is the nearest to the earth. In which sense it stands opposed to Apogee, which is the most distant point from the earth.

PERIGEE, in the Ancient Aſtronomy, denotes a point in a planet's orbit, where the centre of its epicycle is at the leaſt diſtance from the earth.

PERIHELION, PERIHELIUM, that point in the orbit of a planet or comet which is neareſt to the ſun. In which ſenſe it ſtands oppoſed to Aphelion, or Aphelium, which is the higheſt or moſt diſtant point from the ſun.

Inſtead of this term, the Ancients uſed Perigeum; becauſe they placed the earth in the centre.

PERIMETER, in Geometry, the ambit, limit, or outer bounds of a figure; being the ſum of all the lines by which it is incloſed or formed.

In circular figures, &c, inſtead of this term, the word circumference or periphery is uſed.

PERIOD, in Aſtronomy, the time in which a ſtar or planet makes one revolution, or returns again to the ſame point in the heavens.

The ſun's, or properly the earth's tropical period, is 365 days 5 hours 48 minutes 45 ſeconds 30 thirds. That of the moon is 27 days 7 hours 43 minutes. That of the other planets as below.

There is a wonderful harmony between the diſtances of the planets from the ſun, and their Periods round him; the great law of which is, that the ſquares of the Periodic times are always proportional to the cubes of their mean diſtances from the ſun.

The Periods, both tropical and ſydereal, with the proportions of the mean diſtances of the ſeveral planets are as follow:

Planets	Tropical Periods	Sydereal Periods	Proport. Diſts.
Mercury	87d 23h 14′	87d 23h 16′	36710
Venus	224 16 42	224 16 49	72333
Earth	365 5 49	365 6 9	100000
Mars	686 22 18	686 23 31	152369
Jupiter	4330 8 58	4332 8 51	520110
Saturn	10749 7 22	10761 14 37	953800
Georgian or Herſchel	30456 1 41		1908180

As to the comets, the Periods of very few of them are known. There is one however of between 75 and 76 years, which appeared for the laſt time in 1759; another was ſuppoſed to have its Period of 129 years, which was expected to appear in 1789 or 1790, but it did not; and the comet which appeared in 1680 it is thought has its Period of 575 years.

PERIOD, in Chronology, denotes an epoch, or interval of time, by which the years are reckoned; or a ſeries of years by which time is meaſured, in different nations. Such are the Calippic and Metonic Periods, two different corrections of the Greek calendar, the Julian Period, invented by Joſeph Scaliger; the Victorian Period, &c.

Calippic PERIOD. See CALIPPIC *Period.*

Conſtantinopolitan PERIOD, is that uſed by the Greeks, and is the ſame as the *Julian* PERIOD, which ſee.

Chaldaic PERIOD. See SAROS.

Dionyſian PERIOD. See *Victorian* PERIOD.

Hipparchus's PERIOD, is a ſeries or cycle of 304 ſolar years, returning in a conſtant round, and reſtoring the new and full moons to the ſame day of the ſolar year; as Hipparchus thought.

This Period ariſes by multiplying the Calippic Period by 4. Hipparchus aſſumed the quantity of the ſolar year to be 365d. 5h. 55m. 12 ſec. and hence he concluded, that in 304 years Calippus's Period would err a whole day. He therefore multiplied the Period by 4, and from the product caſt away an entire day. But even this does not reſtore the new and full moons to the ſame day throughout the whole Period: but they are ſometimes anticipated 1d. 8h. 23 m. 29 ſec. 20 thirds.

Julian PERIOD, ſo called as being adapted to the Julian year, is a ſeries of 7980 Julian years; ariſing from the multiplications of the cycles of the ſun, moon, and indiction together, or the numbers 28, 19, 15; commencing on the 1ſt day of January in the 764th Julian year before the creation, and therefore is not yet completed. This comprehends all other cycles, Periods and epochs, with the times of all memorable actions and hiſtories; and therefore it is not only the moſt general, but the moſt uſeful of all Periods in Chronology.

As every year of the Julian Period has its particular ſolar, lunar, and indiction cycles, and no two years in it can have all theſe three cycles the ſame, every year of this Period becomes accurately diſtinguiſhed from another.

This Period was invented by Joſeph Scaliger, as containing all the other epochs, to facilitate the reduction of the years of one given epoch to thoſe of another. It agrees with the Conſtantinopolitan Period, uſed by the Greeks, except in this, that the cycles of the ſun, moon, and indiction, are reckoned differently; and alſo in that the firſt year of the Conſtantinopolitan Period differs from that of the Julian Period.

To find the year anſwering to any given year of the Julian Period, and vice verſa; ſee EPOCH.

Metonic PERIOD. See CYCLE *of the Moon.*

Victorian PERIOD, an interval of 532 Julian years; at the end of which, the new and full moons return again on the ſame day of the Julian year, according to the opinion of the inventor Victorinus, or Victorius, who lived in the time of pope Hilary.

Some aſcribe this Period to Dionyſius Exiguus, and hence they call it the Dionyſian Period: others again call it the Great Paſchal Cycle, becauſe it was invented for computing the time of Eaſter.

The Victorian Period is produced by multiplying the ſolar cycle 28 by the lunar cycle 19, the product being 532. But neither does this reſtore the new and full moons to the ſame day throughout its whole duration, by 1d. 16h. 58m. 59s. 40 thirds.

PERIOD, in Arithmetic, is a diſtinction made by a point, or a comma, after every 6th place, or figure; and is uſed in numeration, for the readier diſtinguiſhing and naming the ſeveral figures or places, which are thus diſtinguiſhed into Periods of ſix figures each. See NUMERATION.

PERIOD is alſo uſed in Arithmetic, in the extraction

of

of roots, to point off, or separate the figures of the given number into Periods, or parcels, of as many figures each as are expreſſed by the degree of the root to be extracted, viz, of two places each for the ſquare root, three places for the cube root, and ſo on.

PERIODIC, or PERIODICAL, appertaining to Period, or going by periods. Thus, the Periodical motion of the moon, is that of her monthly period or courſe about the earth, called her Periodical month, containing 27 days 7 hours 45 minutes.

PERIODICAL *Month*. See MONTH.

PERIŒCI, or PERIOECIANS, in Geography, are ſuch as live in oppoſite points of the ſame parallel of latitude. Hence they have the ſame ſeaſons at the ſame time, with the ſame phenomena of the heavenly bodies; but their times of the day are oppoſite, or differ by 12 hours, being noon with the one when it is midnight with the other.

PERIPATETIC *Philoſophy*, the ſyſtem of philoſophy taught and eſtabliſhed by Ariſtotle, and maintained by his followers, the Peripatetics. See ARISTOTLE.

PERIPATETICS, the followers of Ariſtotle. Though ſome derive their eſtabliſhment from Plato himſelf, the maſter of both Xenocrates and Ariſtotle.

PERIPHERY, in Geometry, is the circumference, or bounding line, of a circle, ellipſe, or other regular curvilineal figure. See CIRCUMFERENCE, and CIRCLE.

PERISCII, or PERISCIANS, thoſe inhabitants of the earth, whoſe ſhadows do, in one and the ſame day, turn quite round to all the points of the compaſs, without diſappearing.

Such are the inhabitants of the two frozen zones, or who live within the compaſs of the arctic and antarctic circles; for, as the ſun never ſets to them, after he is once up, but moves quite round about, ſo do their ſhadows alſo.

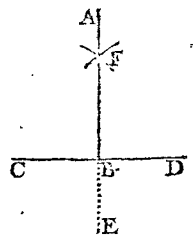
PERISTYLE, in the ancient Architecture, a place or building encompaſſed with a row of columns on the inſide; by which it is diſtinguiſhed from the periptere, where the columns are diſpoſed on the outſide.

PERISTYLE is alſo uſed, by modern writers, for a range of columns, either within or without a building.

PERITROCHIUM, in Mechanics, is a wheel or circle, concentric with the baſe of a cylinder, and moveable together with it, about an axis. The axis, with the wheel, and levers fixed in it to move it, make that mechanical power, called AXIS *in Peritrochio*, which ſee.

PERMUTATIONS *of Quantities*, in Algebra, the ALTERNATIONS, CHANGES, or different COMBINATIONS of any number of things. See thoſe terms.

PERPENDICULAR, in Geometry, or NORMAL. One line is Perpendicular to another, when the former meets the latter ſo as to make the angles on both ſides of it equal to each other. And thoſe angles are called right angles. And hence, to be Perpendicular to, or to make right-angles with, means one and the ſame thing. So, when the angle ABC is equal to the angle ABD, the line AB is ſaid to be Perpendicular, or normal, or at right angles to the line CD.



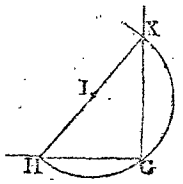
A line is Perpendicular to a curve, when it is perpendicular to the tangent of the curve at the point of contact.

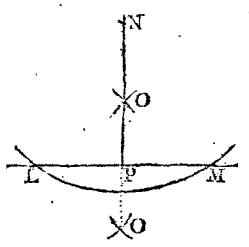
A line is Perpendicular to a plane, when it is Perpendicular to every line drawn in the plane through the bottom of the Perpendicular. And one plane is Perpendicular to another, when a line in the one plane is Perpendicular to the other plane.

From the very principle and motion of a Perpendicular, it follows, 1. That the Perpendicularity is mutual, if the firſt AB is perpendicular to the ſecond CD, then is the ſecond Perpendicular to the firſt.—2. That only one Perpendicular can be drawn from one point in the ſame place.—3. That if a Perpendicular be continued through the line it was drawn Perpendicular to; the continuation BE will alſo be Perpendicular to the ſame.—4. That if there be two points, A and E, of a right line, each of which is at an equal diſtance from two points, C and D, of another right line; thoſe lines are Perpendiculars.—5. That a line which is Perpendicular to another line, is alſo Perpendicular to all the parallels of the other.—6. That a Perpendicular is the ſhorteſt of all thoſe lines which can be drawn from the ſame point to the ſame right line. Hence the diſtance of a point from a line or plane, is a line drawn from the point Perpendicular to the line or plane: and hence alſo the altitude of a figure is a Perpendicular let fall from the vertex to the baſe.

To Erect a Perpendicular from a given point in a line.—1. When the given point B is near the middle of the line; with any interval in the compaſſes take the two equal parts BC, BD: and from the two centres C and D, with any radius greater than BC or BD, ſtrike two arcs interſecting in F; then draw BFA the Perpendicular required.

2. When the given point G is at or near the end of the line; with any centre I and radius IG deſcribe an arc HGK through G; then a ruler laid by H and I will cut the arc in the point K, through which the Perpendicular GK muſt be drawn.





To let fall a Perpendicular upon a given line LM from a given point N. With the centre N, and a convenient radius, deſcribe an arc cutting the given line in L and M; with theſe two centres, and any other convenient radius, ſtrike

two other arcs interſecting in O, the point through which the Perpendicular NOP muſt be drawn.

Note, that Perpendiculars are beſt drawn, in practice, by means of a ſquare, laying one ſide of it along the given line, and the other to paſs through the given point.

PERPENDICULAR, in Gunnery, is a ſmall inſtrument uſed for finding the centre line of a piece, in the operation of pointing it to a given object. See *Pointing of a* GUN.

PERPETUAL *Motion*. See MOTION.

Circle of PERPETUAL *Occultation and Apparition*. See CIRCLE.

PERPETUAL, or *Endleſs Screw*. See SCREW.

PERPETUITY, in the Doctrine of Annuities, is the number of years in which the ſimple intereſt of any principal ſum will amount to the ſame as the principal itſelf. Or it is the quotient ariſing by dividing 100, or any other principal, by its intereſt for one year. Thus, the Perpetuity, at the rate of 5 per cent. intereſt, is $\frac{100}{5} = 20$; at 4 per cent. $\frac{100}{4} = 25$; &c.

PERRY (Captain JOHN), was a celebrated Engliſh engineer. After acquiring great reputation for his ſkill in this country, he reſided many years in Ruſſia, having been recommended to the czar Peter while in England, as a perſon capable of ſerving him on a variety of occaſions relating to his new deſign of eſtabliſhing a fleet, making his rivers navigable, &c. His ſalary in this ſervice was to be 300l. per annum, beſides travelling expences and ſubſiſtence money on whatever ſervice he ſhould be employed, with a farther reward to his ſatisfaction at the concluſion of any work he ſhould finiſh.

After ſome converſation with the czar himſelf, particularly reſpecting a communication between the rivers Volga and Don, he was employed on that work for three ſummers ſucceſſively; but not being well ſupplied with men, partly on account of the ill ſucceſs of Peter's arms againſt the Swedes at the battle of Narva, and partly by the diſcouragement of the governor of Aſtracan, he was ordered at the end of 1707 to ſtop, and next year was employed in refitting the ſhips at Veroniſe, and 1709 in making the river of that name navigable. But after repeated diſappointments, and a variety of fruitleſs applications for his ſalary, he at length quitted the kingdom, under the protection of Mr. Whitworth, the Engliſh ambaſſador, in 1712. (See his Narrative in the Preface to *The State of Ruſſia*.)

In 1721 he was employed in ſtopping the breach at Dagenham, made in the bank of the river Thames, near the village of that name in Eſſex, and about 3 miles below Woolwich, in which he happily ſucceeded, after ſeveral other perſons had failed in that undertaking. He was alſo employed, the ſame year, about the harbour at Dublin, and publiſhed at that time an Anſwer to the objections made againſt it.—Beſide this piece, Captain Perry was author of, *The State of Ruſſia*, 1716, 8vo; and *An Account of the Stopping of Dagenham Breach*, 1721, 8vo.—He died February the 11th 1733.

PERSEUS, a conſtellation of the northern hemiſphere, being one of the 48 ancient aſteriſms.

The Greeks fabled that this is Perſeus, whom they make the ſon of Jupiter by Danae. The father of that lady had been told, that he ſhould be killed by his grandchild, and having only Danae to take care of, he locked her up; but Jupiter found his way to her in a ſhower of gold, and Perſeus verified the oracle. He cut off alſo the head of the gorgon, and affixed it to his ſhield; and after many other great exploits he reſcued Andromeda, the daughter of Caſſiopeia, whom the ſea-nymphs, in revenge for that lady's boaſting of ſuperior beauty, had faſtened to a rock to be devoured by a monſter. Jupiter his father in honour of the exploit, they ſay, afterwards took up the hero, and the whole family with him, into the ſkies.

The number of ſtars in this conſtellation, in Ptolomy's catalogue, are 29; in Tycho's 29, in Hevelius's 46, and in the Britannic catalogue 59.

PERSIAN *Wheel*, in Mechanics, a machine for raiſing a quantity of water, to ſerve for various purpoſes. Such a wheel is repreſented in plate xx, fig. 1; with which water may be raiſed by means of a ſtream AB turning a wheel CDE, according to the order of the letters, with buckets *a*, *a*, *a*, *a*, &c, hung upon the wheel by ſtrong pins *b*, *b*, *b*, *b*, &c, fixed in the ſide of the rim; which muſt be made as high as the water is intended to be raiſed above the level of that part of the ſtream in which the wheel is placed. As the wheel turns, the buckets on the right hand go down into the water, where they are filled, and return up full on the left hand, till they come to the top at K; where they ſtrike againſt the end *n* of the fixed trough M, by which they are overſet, and ſo empty the water into the trough; from whence it is to be conveyed in pipes to any place it is intended for: and as each bucket gets over the trough, it falls into a perpendicular poſition again, and ſo goes down empty till it comes to the water at A, where it is filled as before. On each bucket is a ſpring *r*, which going over the top or crown of the bar *m* (fixed to the trough M) raiſes the bottom of the bucket above the level of its mouth, and ſo cauſes it to empty all its water into the trough.

Sometimes this wheel is made to raiſe water no higher than its axis; and then inſtead of buckets hung upon it, its ſpokes C, *d*, *e*, *f*, *g*, *h*, are made of a bent form, and hollow within; theſe hollows opening into the holes C, D, E, F, in the outſide of the wheel, and alſo into thoſe at O in the box N upon the axis. So that, as the holes C, D, &c, dip into the water, it runs into them; and as the wheel turns, the water riſes in the hollow ſpokes, *c*, *d*, &c, and runs out in a ſtream P from the holes at O, and falls into the trough Q, from whence it is conveyed by pipes.

PERSIAN, or PERSIC, in Architecture, a name common to all ſtatues of men; ſerving inſtead of columns to ſupport entablatures.

PERSIAN *Era* and *Year*. See EPOCH and YEAR.

PERSPECTIVE, the art of delineating viſible objects on a plane ſurface, ſuch as they appear at a given diſtance, or height, upon a tranſparent plane, placed commonly perpendicular to the horizon, between the eye and the object. This is particularly called

Linear PERSPECTIVE, as regarding the poſition, magnitude, form, &c, of the ſeveral lines, or contours of objects, and expreſſing their diminution.

Some make this a branch of Optics; others an art

and ſcience derived from it: its operations however are all geometrical.

Hiſtory of PERSPECTIVE. This art derives its origin from painting, and particularly from that branch of it which was employed in the decorations of the theatre, where landſcapes were chiefly introduced. Vitruvius, in the proem to his 7th book, ſays that Agatharchus, at Athens, was the firſt author who wrote upon this ſubject, on occaſion of a play exhibited by Æſchylus, for which he prepared a tragic ſcene; and that afterwards the principles of the art were more diſtinctly taught in the writings of Democritus and Anaxagoras, the diſciples of Agatharchus, which are not now extant.

The Perſpective of Euclid and of Heliodorus Lariſſeus contains only ſome general elements of optics, that are by no means adapted to any particular practice; though they furniſh ſome materials that might be of ſervice even in the linear Perſpective of painters.

Geminus, of Rhodes, a celebrated mathematician, in Cicero's time, alſo wrote upon this ſcience.

It is alſo evident that the Roman artiſts were acquainted with the rules of Perſpective, from the account which Pliny (Nat. Hiſt. lib. 35, cap. 4) gives of the repreſentation on the ſcene of thoſe plays given by Claudius Pulcher; by the appearance of which the crows were ſo deceived, that they endeavoured to ſettle on the fictitious roofs. However, of the theory of this Art among the Ancients we know nothing; as none of their writings have eſcaped the general wreck of ancient literature in the dark ages of Europe. Doubtleſs this art muſt have been loſt, when painting and ſculpture no longer exiſted. However, there is reaſon to believe that it was practiſed much later in the Eaſtern empire.

John Tzetzes, in the 12th century, ſpeaks of it as well acquainted with its importance in painting and ſtatuary. And the Greek painters, who were employed by the Venetians and Florentines, in the 13th century, it ſeems brought ſome optical knowledge along with them into Italy: for the diſciples of Giotto are commended for obſerving Perſpective more regularly than any of their predeceſſors in the art had done; and he lived in the beginning of the 14th century.

The Arabians were not ignorant of this art; as may be preſumed from the optical writings of Alhazen, about the year 1100. And Vitellus, a Pole, about the year 1270, wrote largely and learnedly on optics. And, of our own nation, friar Bacon, as well as John Peckham, archbiſhop of Canterbury, treated this ſubject with ſurpriſing accuracy, conſidering the times in which they lived.

The firſt authors who profeſſedly laid down rules of Perſpective, were Bartolomeo Bramantino, of Milan, whoſe book, Regole di Perſpectiva, e Miſure delle Antichita di Lombardia, is dated 1440; and Pietro del Borgo, likewiſe an Italian, who was the moſt ancient author met with by Ignatius Danti, and who it is ſuppoſed died in 443. This laſt writer ſuppoſed objects placed beyond a tranſparent tablet, and ſo to trace the images, which rays of light, emitted from them, would make upon it. And Albert Durer conſtructed a machine upon the principles of Borgo, by which he could trace the Perſpective appearance of objects.

Leon Battiſta Alberti, in 1450, wrote his treatiſe De Pictura, in which he treats chiefly of Perſpective.

Balthazar Peruzzi, of Siena, who died in 1536, had diligently ſtudied the writings of Borgo; and his method of Perſpective was publiſhed by Serlio in 1540. To him it is ſaid we owe the diſcovery of points of diſtance, to which are drawn all lines that make an angle of 45° with the ground line.

Guido Ubaldi, another Italian, ſoon after diſcovered, that all lines that are parallel to one another, if they be inclined to the ground line, converge to ſome point in the horizontal line; and that through this point alſo will paſs a line drawn from the eye parallel to them. His Perſpective was printed at Piſaro in 1600, and contained the firſt principles of the method afterwards diſcovered by Dr. Brook Taylor.

In 1583 was publiſhed the work of Giacomo Barozzi, of Vignola, commonly called Vignola, intitled The two Rules of Perſpective, with a learned commentary by Ignatius Danti. In 1615 Marolois' work was printed at the Hague, and engraved and publiſhed by Hondius. And in 1625, Sirigatti publiſhed his treatiſe of Perſpective, which is little more than an abſtract of Vignola's.

Since that time the art of Perſpective has been gradually improved by ſubſequent geometricians, particularly by profeſſor Graveſande, and ſtill more by Dr. Brook Taylor, whoſe principles are in a great meaſure new, and far more general than thoſe of any of his predeceſſors. He did not confine his rules, as they had done, to the horizontal plane only, but made them general, ſo as to affect every ſpecies of lines and planes, whether they were parallel to the horizon or not; and thus his principles were made univerſal. Beſides, from the ſimplicity of his rules, the tedious progreſs of drawing out plans and elevations for any object, is rendered uſeleſs, and therefore avoided; for by this method, not only the feweſt lines imaginable are required to produce any Perſpective repreſentation, but every figure thus drawn will bear the niceſt mathematical examination. Farther, his ſyſtem is the only one calculated for anſwering every purpoſe of thoſe who are practitioners in the art of deſign; for by it they may produce either the whole, or only ſo much of an object as is wanted; and by fixing it in its proper place, its apparent magnitude may be determined in an inſtant. It explains alſo the Perſpective of ſhadows, the reflection of objects from poliſhed planes, and the inverſe practice of Perſpective.

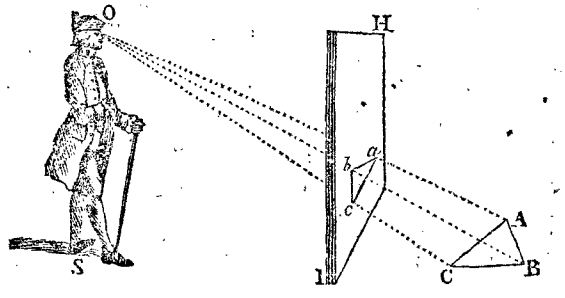
His Linear Perſpective was firſt publiſhed in 1715; and his New Principles of Linear Perſpective in 1719, which he intended as an explanation of his firſt treatiſe. And his method has been chiefly followed by all others ſince.

In 1738 Mr. Hamilton publiſhed his Stereography, in 2 vols folio, after the manner of Dr. Taylor. But the neateſt ſyſtem of Perſpective, both as to theory and practice, on the ſame principles, is that of Mr. Kirby. There are alſo good treatiſes on the ſubject, by Deſargues, de Boſſe, Albertus, Lamy, Niceron, Pozzo the Jeſuit, Ware, Cowley, Prieſtley, Ferguſon, Emerſon, Malton, Henry Clarke, &c, &c.

Of the Principles of PERSPECTIVE. To give an idea of

of the firſt principles and nature of this art; ſuppoſe a tranſparent plane, as of glaſs &c, HI raiſed perpendicularly on a horizontal plane; and the ſpectator S directing his eye O to the triangle ABC: if now we conceive the rays AO, BO, CO, &c, in their paſſage through the plane, to leave their traces or veſtiges in *a*, *b*, *c*, &c, on the plane; there will appear the triangle *abc*; which, as it ſtrikes the eye by the ſame rays *a*O, *b*O, *c*O, by which the reflected particles of light from the triangle are tranſmitted to the ſame, it will exhibit the true appearance of the triangle ABC, though the object ſhould be removed, the ſame diſtance and height of the eye being preſerved.

The buſineſs of Perſpective then, is to ſhew by what certain rules the points *a*, *b*, *c*, &c, may be found geometrically: and hence alſo we have a mechanical method of delineating any object very accurately.



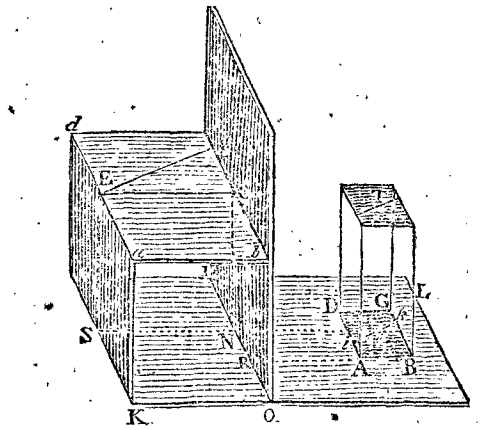
Hence it appears that *abc* is the ſection of the plane of the picture with the rays, which proceed from the original object to the eye: and therefore, when this is parallel to the picture, its repreſentation will be both parallel to the original, and ſimilar to it, though ſmaller in proportion as the original object is farther from the picture. When the original object is brought to coincide with the picture, the repreſentation is equal to the original; but as the object is removed farther and farther from the picture, its image will become ſmaller and ſmaller, and alſo riſe higher and higher in the picture, till at laſt, when the object is ſuppoſed to be at an infinite diſtance, its image will vaniſh in an imaginary point, exactly as high above the bottom of the picture as the eye is above the ground plane, upon which the ſpectator, the picture, and the original object are ſuppoſed to ſtand.

This may be familiarly illuſtrated in the following manner: Suppoſe a perſon at a window looks through an upright pane of glaſs at any object beyond; and, keeping his head ſteady, draws the figure of the object upon the glaſs, with a black-lead pencil, as if the point of the pencil touched the object itſelf; he would then have a true repreſentation of the object in Perſpective, as it appears to his eye. For properly drawing upon the glaſs, it is neceſſary to lay it over with ſtrong gum water, which will be fit for drawing upon when dry, and will then retain the traces of the pencil. The perſon ſhould alſo look through a ſmall hole in a thin plate of metal, fixed about a foot from the glaſs, between it and his eye; keeping his eye cloſe to the hole, otherwiſe he might ſhift the poſition of his head, and ſo make a falſe delineation of the object.

Having traced out the figure of the object, he may go over it again, with pen and ink; and when that is dry, cover it with a ſheet of paper, tracing the image upon this with a pencil; then taking away the paper, and laying it upon a table, he may finiſh the picture, by giving it the colours, lights, and ſhades, as he ſees them in the object itſelf; and thus he will have a true reſemblance of the object on the paper.

Of certain Definitions in PERSPECTIVE.

The point of ſight, in Perſpective, is the point E, where the ſpectator's eye ſhould be placed to view the



picture. And the *point of ſight*, in the picture, called alſo the *centre of the picture*, is the point C directly oppoſite to the eye, where a perpendicular from the eye at E meets the picture. Alſo this perpendicular EC is the *diſtance of the picture*: and if this diſtance be tranſferred to the horizontal line on each ſide of the point C, as is ſometimes done, the extremes are called the points of diſtance.

The *original plane*, or *geometrical plane*, is the plane KL upon which the real or original object ABGD is ſituated. The line OI, where the ground plane cuts the bottom of the picture, is called the *ſection* of the original plane, the *ground-line*, the *line of the baſe*, or the *fundamental line*.

If an original line AB be continued, ſo as to interſect the picture, the point of interſection R is called the interſection of that original line, or its *interſecting point*. The *horizontal plane* is the plane *abgd*, which paſſes through the eye, parallel to the horizon, and cuts the Perſpective plane or picture at right angles; and the *horizontal line bg* is the common interſection of the horizontal plane with the picture.

The *vertical plane* is that which paſſes through the eye at right angles both to the ground plane and to the picture, as ECSN. And the *vertical line* is the common ſection of the vertical plane and the picture, as CN.

The *line of ſtation* SN is the common ſection of the vertical plane with the ground plane, and perpendicular to the ground line OI.

The

The *line of the height of the eye* is a perpendicular, as ES, let fall from the eye upon the ground plane.

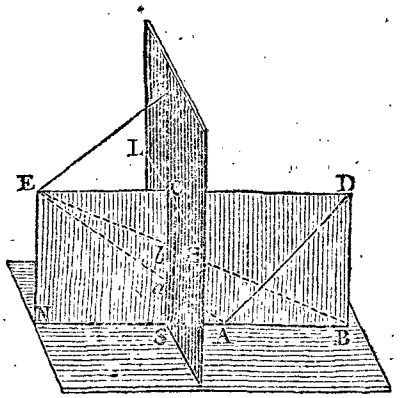
The *vaniſhing line* of the original plane, is that line where a plane paſſing through the eye, parallel to the original plane, cuts the picture: thus *bg* is the vaniſhing line of ABGD, being the greateſt height to which the image can riſe, when the original object is infinitely diſtant.

The *vaniſhing point* of the original line, is that point where a line drawn from the eye, parallel to that original line, interſects the picture: thus C and *g* are the vaniſhing points of the lines AB and *ki*. All lines parallel to each other have the ſame vaniſhing point.

If from the point of ſight a line be drawn perpendicular to any vaniſhing line, the point where that line interſects the vaniſhing line, is called the centre of that vaniſhing line: and the *diſtance of a vaniſhing line* is the length of the line which is drawn from the eye, perpendicular to the ſaid line.

Meaſuring points are points from which any lines in the Perſpective plane are meaſured, by laying a ruler from them to the diviſions laid down upon the ground line. The meaſuring point of all lines parallel to the ground line, is either of the points of diſtance on the horizontal line, or point of ſight. The meaſuring point of any line perpendicular to the ground line, is in the point of diſtance on the horizontal line; and the meaſuring point of a line oblique to the ground line is found by extending the compaſſes from the vaniſhing point of that line to the point of diſtance on the perpendicular, and ſetting off on the horizontal line.

Some general Maxims or Theorems in PERSPECTIVE.

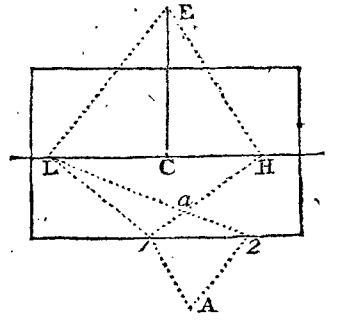


1. The repreſentation *ab*, of a line AB, is part of a line SC, which paſſes through the interſecting point S, and the vaniſhing point C, of the original line AB.

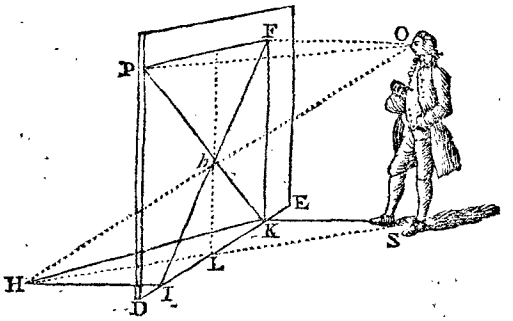
2. If the original plane be parallel to the picture, it can have no vaniſhing line upon it; conſequently the repreſentation will be parallel. When the original is perpendicular to the ground line, as AB, then its vaniſhing point is in C, the centre of the picture, or point of ſight; becauſe EC is perpendicular to the picture, and therefore parallel to AB.

3. The image of a line bears a certain proportion to its original. And the image may be determined by transferring the length or diſtance of the given line to the interſecting line; and the diſtance of the vaniſhing point to the horizontal line; i. e. by bringing both into the plane of the picture.

PROB. *To find the repreſentation of an Objective point* A.—Draw A1 and A2 at pleaſure, interſecting the bottom of the picture in 1 and 2; and from the eye E draw EH parallel to A1, and EL parallel to A2; then draw H1 and L2, which will interſect each other in *a*, the repreſentation of the point A.



OTHERWISE. Let H be the given objective point.



From which draw HI perpendicular to the fundamental line DE. From the fundamental line DE cut off IK = IH: through the point of ſight F draw a horizontal line FP, and make FP equal to the diſtance of the eye SK: laſtly, join FI and PK, and their interſection *h* will be the appearance of the given objective point H; as required.

And thus, by finding the repreſentations of the two points, which are the extremes of a line, and connecting them together, there will be formed the repreſentation of the line itſelf. In like manner, the repreſentations of all the lines or ſides of any figure or ſolid, determine thoſe of the ſolid itſelf; which therefore are thus put into Perſpective.

Aerial PERSPECTIVE, is the art of giving a due diminution or gradation to the ſtrength of light, ſhade, and colours of objects, according to their different diſtances, the quantity of light which falls upon them, and the medium through which they are ſeen.

PERSPECTIVE *Machine*, is a machine for readily and eaſily making the Perſpective drawing and appearance of any object, with little or no ſkill in the art. There have been invented various machines of this kind. One of which may even be ſeen in the works of Albert Durer.

Durer. A very convenient one was invented by Dr. Bevis, and is described by Mr. Ferguſon, in his Perſpective, pa. 113. And another is deſcribed in Kirby's Perſpective, pa. 65.

PERSPECTIVE *Plan*, or *Plane*, is a glaſs or other tranſparent ſurface ſuppoſed to be placed between the eye and the object, and uſually perpendicular to the horizon.

Scenographic PERSPECTIVE. See SCENOGRAPHY.

PERSPECTIVE *of Shadows*. See SHADOW.

Specular PERSPECTIVE, is that which repreſents the objects in cylindrical, conical, ſpherical, or other mirrors.

PERTICA, a ſort of comet, being the ſame with VERU.

PETARD, a military engine, ſomewhat reſembling in ſhape a high-crowned hat; ſerving formerly to break down gates, barricades, draw-bridges, or the like works intended to be ſurpriſed. It is about 8 or 9 inches wide, and weighs from 55 to 70 pounds. Its uſe was chiefly in a clandeſtine or private attack, to break down the gates &c. It has alſo been uſed in countermines, to break through the enemies galleries, and give vent to their mines: but the uſe of Petards is now diſcontinued.——Their invention is aſcribed to the French Hugonots in the year 1579. Their moſt ſignal exploit was the taking the city Cahors by means of them, as we are told by d'Aubigné.

PETIT (PETER), a conſiderable mathematician and philoſopher of France, was born at Montluçon in the dioceſe of Bourges, in the year 1589 according to ſome, but in 1600 according to others. — He firſt cultivated the mathematics and philoſophy in the place of his nativity; but in 1633 he repaired to Paris, to which place his reputation had procured him an invitation. Here he became highly celebrated for his ingenious writings, and for his connections with Paſcal, Des Cartes, Merſenne, and the other great men of that time. He was employed on ſeveral occaſions by cardinal Richelieu; he was commiſſioned by this miniſter to viſit the ſea-ports, with the title of the king's engineer; and was alſo ſent into Italy upon the king's buſineſs. He was at Tours in 1640, where he married; and was afterwards made intendant of the fortifications. Baillet, in his Life of Des Cartes, ſays, that Petit had a great genius for mathematics; that he excelled particularly in aſtronomy; and had a ſingular paſſion for experimental philoſophy. About 1637 he returned to Paris from Italy, when the Dioptrics of Des Cartes were much ſpoken of. He read them, and communicated his objections to Merſenne, with whom he was intimately acquainted. And yet he ſoon after embraced the principles of Des Cartes, becoming not only his friend, but his partiſan and defender alſo. He was intimately connected with Paſcal, with whom he made at Rouen the ſame experiments concerning the vacuum, which Torricelli had before made in Italy; and was aſſured of their truth by frequent repetitions. This was in 1646 and 1647; and though there appears to be a long interval from this date to the time of his death, we meet with no other memoirs of his life. He died Auguſt the 20th 1667 at Lagny, near Paris, whither he had retired for ſome time before his deceaſe.

Petit was the author of ſeveral works upon phyſical and aſtronomical ſubjects; the principal of which are,

1. Chronological Diſcourſe, &c, 1636, 4to. In defence of Scaliger.
2. Treatiſe on the Proportional Compaſſes.
3. On the Weight and Magnitude of Metals.
4. Conſtruction and Uſe of the Artillery Calipers.
5. On a Vacuum.
6. On Eclipſes.
7. On Remedies againſt the Inundations of the Seine at Paris.
8. On the Junction of the Ocean with the Mediterranean ſea, by means of the rivers Aude and Garonne.
9. On Comets.
10. On the proper Day for celebrating Eaſter.
11. On the Nature of Heat and Cold, &c.

PETTY (Sir WILLIAM), a ſingular inſtance of a univerſal genius, was the elder ſon of Anthony Petty, a clothier at Rumſey in Hampſhire, where he was born May the 16th, 1623. While a boy he took great delight in ſpending his time among the artificers there, whoſe trades he could work at when but 12 years of age. He then went to the grammar-ſchool in that place, where at 15 he became maſter of the Latin, Greek, and French languages, with arithmetic and thoſe parts of practical geometry and aſtronomy uſeful in navigation. Soon after, he went to the univerſity of Caen in Normandy; and after ſome ſtay there he returned to England, where he was preferred in the king's navy. In 1643, when the civil war grew hot, and the times troubleſome, he went into the Netherlands and France for three years; and having vigorouſly proſecuted his ſtudies, eſpecially in phyſic, at Utrecht, Leyden, Amſterdam, and Paris, he returned home to Rumſey. In 1647 he obtained a patent to teach the art of double writing for 17 years. In 1648 he publiſhed at London, "Advice to Mr. Samuel Hartlib, for the advancement of ſome particular parts of learning." At this time he adhered to the prevailing party of the nation; and went to Oxford, where he taught anatomy and chemiſtry, and was created a doctor of phyſic, and grew into ſuch repute that the philoſophical meetings, which preceded and laid the foundation of the Royal Society, were firſt held at his houſe. In 1650 he was made profeſſor of anatomy there; and ſoon after a member of the college of phyſicians in London, as alſo profeſſor of muſic at Greſham college London. In 1652 he was appointed phyſician to the army in Ireland; as alſo to three lord lieutenants ſucceſſively, Lambert, Fleetwood, and Henry Cromwell. In Ireland he acquired a great fortune, but not without ſuſpicions and charges of unfair practices in his offices. After the rebellion was over in Ireland, he was appointed one of the commiſſioners for dividing the forfeited lands to the army who ſuppreſſed it. When Henry Cromwell became lieutenant of that kingdom, in 1655, he appointed Dr. Petty his ſecretary, and clerk of the council: he likewiſe procured him to be elected a burgeſs for Weſtloo in Cornwall, in Richard Cromwell's parliament, which met in January 1658. But, in March following, Sir Hierom Sankey, member for Woodſtock in Oxfordſhire, impeached him of high crimes and miſdemeanors in the execution of his office.

This

This gave the doctor a great deal of trouble, as he was ſummoned before the Houſe of Commons; and notwithſtanding the ſtrenuous endeavours of his friends, in their recommendations of him to ſecretary Thurloe, and the defence he made before the houſe, his enemies procured his diſmiſſion from his public employments, in 1659. He then retired to Ireland, till the reſtoration of king Charles the Second; ſoon after which he came into England, where he was very graciouſly received by the king, reſigned his profeſſorſhip at Greſham college, and was appointed one of the commiſſioners of the Court of Claims. Likewiſe, April the 11th, 1661, he received the honour of knighthood, and the grant of a new patent, conſtituting him ſurveyor-general of Ireland, and was choſen a member of parliament there.

Upon the incorporating of the Royal Society, he was one of the firſt members, and of its firſt council. And though he had left off the practice of phyſic, his name was continued as an honorary member of the college of phyſicians in 1663.

About this time he invented his double bottomed ſhip, to ſail againſt wind and tide, and afterwards preſented a model of this ſhip to the Royal Society; to whom alſo, in 1665, he communicated "A Diſcourſe about the Building of Ships," containing ſome curious ſecrets in that art. But, upon trial, finding his ſhip failed in ſome reſpects, he at length gave up that project.

In 1666 Sir William drew up a treatiſe, called *Verbum Sapienti*, containing an account of the wealth and expences of England, and the method of raiſing taxes in the moſt equal manner.—The ſame year, 1666, he ſuffered a conſiderable loſs by the fire of London.—The year following he married Elizabeth, daughter of Sir Hardreſſe Waller; and afterwards ſet up iron works and pilchard fiſhing, opened lead mines and a timber trade in Kerry, which turned to very good account. But all theſe concerns did not hinder him from the purſuit of both political and philoſophical ſpeculations, which he thought of public utility, publiſhing them either ſeparately or by communication to the Royal Society, particularly on finances, taxes, political arithmetic, land carriage, guns, pumps, &c.

Upon the firſt meeting of the Philoſophical Society at Dublin, upon the plan of that at London, every thing was ſubmitted to his direction; and when it was formed into a regular ſociety, he was choſen preſident in Nov. 1684. Upon this occaſion he drew up a "Catalogue of mean, vulgar, cheap, and ſimple Experiments," proper for the infant ſtate of the ſociety, and preſented it to them; as he did alſo his *Supellex Philoſophica*, conſiſting of 45 inſtruments requiſite to carry on the deſign of their inſtitution. In 1685 he made his will; in which he declares, that being then about 60, his views were fixed upon improving his lands in Ireland, and to promote the trade of iron, lead, marble, fiſh, and timber, which his eſtate was capable of. And as for ſtudies and experiments, "I think now, ſays he, to confine the ſame to the anatomy of the people, and political arithmetic; as alſo the improvement of ſhips, land-carriages, guns, and pumps, as of moſt uſe to mankind, not blaming the ſtudy of other men." But a few years after, all his purſuits were determined by the effects of a gangrene in his foot, occaſioned by the ſwelling of the gout, which put a period to his life, at his houſe in Piccadilly, Weſtminſter, Dec. 16, 1687, in the 65th year of his age. His corpſe was carried to Rumſey, and there interred, near thoſe of his parents.

Sir William Petty died poſſeſſed of a very large fortune, as appears by his will; where he makes his real eſtate about 6,500l. per annum, his perſonal eſtate about 45,000l. his bad and deſperate debts 30,000l. and the demonſtrable improvements of his Iriſh eſtate, 4000l. per annum; in all, at 6 per cent. intereſt, 15,000l. per annum. This eſtate came to his family, which conſiſted of his widow and three children, Charles, Henry, and Anne: of whom Charles was created baron of Shelbourne, in the county of Waterford in Ireland, by king William the Third; but dying without iſſue, was ſucceeded by his younger brother Henry, who was created viſcount Dunkeron, in the county of Kerry, and earl of Shelbourne Feb. 11, 1718. He married the lady Arabella Boyle, ſiſter of Charles earl of Cork, who brought him ſeveral children. He was member of parliament for Great Marlow in Buckinghamſhire, and a fellow of the Royal Society: he died April 17, 1751. Anne was married to Thomas Fitzmorris, baron of Kerry and Lixnaw, and died in Ireland in the year 1737.

The variety of purſuits, in which Sir William Petty was engaged, ſhews him to have had a genius capable of any thing to which he choſe to apply it: and it is very extraordinary, that a man of ſo active and buſy a ſpirit could find time to write ſo many things, as it appears he did, by the following catalogue.

1. Advice to Mr. S. Hartlib &c; 1648, 4to.—2. A Brief of Proceedings between Sir Hierom Sankey and the author &c; 1659, folio.—3. Reflections upon ſome perſons and things in Ireland, &c; 1660, 8vo.—4. A Treatiſe of Taxes and Contribution, &c; 1662, 1667, 1685, 4to, all without the author's name. This laſt was re-publiſhed in 1690, with two other anonymous pieces, "The Privileges and Practice of Parliaments," and "The Politician Diſcovered;" with a new title-page, where it is ſaid they were all written by Sir William, which, as to the firſt, is a miſtake.—5. Apparatus to the Hiſtory of the Common Practice of Dyeing;" printed in Sprat's *Hiſtory* of the Royal Society, 1667, 4to.—6. A Diſcourſe concerning the Uſe of Duplicate Proportion, together with a New Hypotheſis of Springing or Elaſtic Motions; 1674, 12mo.—7. Colloquium Davidis cum Anima ſua, &c; 1679, folio.—8. The Politician Diſcovered, &c; 1681, 4to.—9. An Eſſay in Political Arithmetic; 1682, 8vo.—10. Obſervations upon the Dublin Bills of Mortality in 1681, &c; 1683, 8vo.—11. An Account of ſome Experiments relating to Land-carriage, Philoſ. Tranſ. numb. 161.—12. Some Queries for examining Mineral Waters, ibid. numb. 166.—13. A Catalogue of Mean, Vulgar, Cheap, and Simple Experiments, &c; ibid. numb. 167.—14. Maps of Ireland, being an Actual Survey of the whole Kingdom, &c; 1685, folio.—15. An Eſſay concerning the Multiplication of Mankind; 1686, 8vo.—16. A further Aſſertion concerning the magnitude of London, vindicating it, &c; Philoſ. Tranſ. numb. 185.—17. Two Eſſays in Politi-

cal Arithmetic; 1687, 8vo.—18. Five Eſſays in Political Arithmetic; 1687, 8vo.—19. Obſervations upon London and Rome; 1687, 8vo.

His poſthumous pieces are, (1), Political Arithmetic; 1690, 8vo, and 1755, with his life prefixed.—(2), The Political Anatomy of Ireland, with Verbum Sapienti, 1691, 1719.—(3), A Treatiſe of Naval Philoſophy; 1691, 12mo.—(4), What a complete Treatiſe of Navigation ſhould contain; Philoſ. Tranſ. numb. 198.—(5), A Diſcourſe of making Cloth with Sheep's Wool; in Birch's Hiſt. of the Roy. Soc.—(6), Supellex Philoſophica; ibid.

PHÆNOMENON. See PHENOMENON.

PHARON, the name of a game of chance. See De Moivre's Doctrine of Chances, pa. 77 and 105.

PHASES, in Aſtronomy, the various appearances, or quantities of illumination of the moon, Venus, Mercury, and the other planets, by the ſun. Theſe Phaſes are very obſervable in the moon with the naked eye; by which ſhe ſometimes increaſes, ſometimes wanes, is now bent into horns, and again appears a half circle; at other times ſhe is gibbous, and again a full circular face. And by help of the teleſcope, the like variety of Phaſes is obſerved in Venus, Mars, &c.

Copernicus, a little before the uſe of teleſcopes, foretold, that after ages would find that Venus underwent all the changes of the moon; which prophecy was firſt fulfilled by Galileo, who, directing his teleſcope to Venus, obſerved her Phaſes to emulate thoſe of the moon; being ſometimes full, ſometimes horned, and ſometimes gibbous.

PHASES *of an Eclipſe*. To determine theſe for any time: Find the moon's place in her viſible way for that moment; and from that point as a centre, with the interval of the moon's ſemidiameter, deſcribe a circle: In like manner find the ſun's place in the ecliptic, from which, with the ſemidiameter of the ſun, deſcribe another circle: The interſection of the two circles ſhews the Phaſes of the eclipſe, the quantity of obſcuration, and the poſition of the cuſps or horns.

PHENOMENON, or PHÆNOMENON, an appearance in phyſics, an extraordinary appearance in the heavens, or on earth; either diſcovered by obſervation of the celeſtial bodies, or by phyſical experiments, the cauſe of which is not obvious. Such are meteors, comets, uncommon appearance of ſtars and planets, earthquakes, &c. Such alſo are the effects of the magnet, phoſphorus, &c.

PHILOLAUS, of Crotona, was a celebrated philoſopher of the Ancients. He was of the ſchool of Pythagoras, to whom that philoſopher's Golden Verſes have been aſcribed. He made the heavens his chief object of contemplation; and has been ſaid to be the author of that true ſyſtem of the world which Copernicus afterwards revived; but erroneouſly, becauſe there is undoubted evidence that Pythagoras learned that ſyſtem in Egypt. On that erroneous ſuppoſition however it was, that Bulliald placed the name of Philolaus at the head of two works, written to illuſtrate and confirm that ſyſtem.

"He was (ſays Dr. Enfield, in his Hiſtory of Philoſophy) a diſciple of Archytas, and flouriſhed in the time of Plato. It was from him that Plato purchaſed the written records of the Pythagorean ſyſtem, contrary to an expreſs oath taken by the ſociety of Pythagoreans, pledging themſelves to keep ſecret the myſteries of their ſect. It is probable that among theſe books were the writings of Timæus, upon which Plato formed the dialogue which bore his name. Plutarch relates, that Philolaus was one of the perſons who eſcaped from the houſe which was burned by Cylon, during the life of Pythagoras; but this account cannot be correct. Philolaus was contemporary with Plato, and therefore certainly not with Pythagoras. Interfering in affairs of ſtate, he fell a ſacrifice to political jealouſy.

"Philolaus treated the doctrine of nature with great ſubtlety, but at the ſame time with great obſcurity; referring every thing that exiſts to mathematical principles. He taught, that reaſon, improved by mathematical learning, is alone capable of judging concerning the nature of things: that the whole world conſiſts of infinite and finite; that number ſubſiſts by itſelf, and is the chain by which its power ſuſtains the eternal frame of things; that the Monad is not the ſole principle of things, but that the Binary is neceſſary to furniſh materials from which all ſubſequent numbers may be produced; that the world is one whole, which has a fiery centre, about which the ten celeſtial ſpheres revolve, heaven, the ſun, the planets, the earth, and the moon; that the ſun has a vitreous ſurface, whence the fire diffuſed through the world is reflected, rendering the mirror from which it is reflected viſible; that all things are preſerved in harmony by the law of neceſſity; and that the world is liable to deſtruction both by fire and by water. From this ſummary of the doctrine of Philolaus it appears probable that, following Timæus, whoſe writings he poſſeſſed, he ſo far departed from the Pythagorean ſyſtem as to conceive two independent principles in nature, God and matter, and that it was from the ſame ſource that Plato derived his doctrine upon this ſubject."

PHILOSOPHER, a perſon well verſed in philoſophy; or who makes a profeſſion of, or applies himſelf to, the ſtudy of nature or of morality.

PHILOSOPHICAL TRANSACTIONS, thoſe of the Royal Society. See TRANSACTIONS.

PHILOSOPHIZING, the act of conſidering ſome object of our knowledge, examining its properties, and the phenomena it exhibits, and enquiring into their cauſes or effects, and the laws of them; the whole conducted according to the nature and reaſon of things, and directed to the improvement of knowledge.

The Rules of PHILOSOPHIZING, as eſtabliſhed by Sir Iſaac Newton, are, 1. That no more cauſes of a natural effect be admitted than are true, and ſuffice to account for its phenomena. This agrees with the ſentiments of moſt philoſophers, who hold that nature does nothing in vain; and that it were vain to do that by many things, which might be done by fewer.

2. That natural effects of the ſame kind, proceed from the ſame cauſes. Thus, for inſtance, the cauſe of reſpiration is one and the ſame in man and brute; the cauſe of the deſcent of a ſtone, the ſame in Europe as in America; the cauſe of light, the ſame in the ſun and in culinary fire; and the cauſe of reflection, the ſame in the planets as the earth.

3. Thoſe qualities of bodies which are not capable of being heightened, and remitted, and which are found

in

in all bodies on which experiments can be made, muſt be conſidered as univerſal qualities of all bodies. Thus, the extenſion of body is only perceived by our ſenſes, nor is it perceivable in all bodies: but ſince it is found in all that we have perception of, it may be affirmed of all. So we find that ſeveral bodies are hard; and argue that the hardneſs of the whole only ariſes from the hardneſs of the parts: whence we infer that the particles, not only of thoſe bodies which are ſenſible, but of all others, are likewiſe hard. Laſtly, if all the bodies about the earth gravitate towards the earth, and this according to the quantity of matter in each; and if the moon gravitate towards the earth alſo, according to its quantity of matter; and the ſea again gravitate towards the moon; and all the planets and comets gravitate towards each other: it may be affirmed univerſally, that all bodies in the creation gravitate towards each other. This rule is the foundation of all natural philoſophy.

PHILOSOPHY, the knowledge or ſtudy of nature or morality, founded on reaſon and experience. Literally and originally, the word ſignified a love of wiſdom. But by Philoſophy is now meant the knowledge of the nature and reaſons of things; as diſtinguiſhed from hiſtory, which is the bare knowledge of facts; and from mathematics, which is the knowledge of the quantity and meaſures of things.

Theſe three kinds of knowledge ought to be joined as much as poſſible. Hiſtory furniſhes matter, principles, and practical examinations; and mathematics completes the evidence.

Philoſophy being the knowledge of the reaſons of things, all arts muſt have their peculiar Philoſophy which conſtitutes their theory: not only law and phyſic, but the loweſt and moſt abject arts are not without their reaſons. It is to be obſerved that the bare intelligence and memory of philoſophical propoſitions, without any ability to demonſtrate them, is not Philoſophy, but hiſtory only. However, where ſuch propoſitions are determinate and true, they may be uſefully applied in practice, even by thoſe who are ignorant of their demonſtrations. Of this we ſee daily inſtances in the rules of arithmetic, practical geometry, and navigation; the reaſons of which are often not underſtood by thoſe who practiſe them with ſucceſs. And this ſucceſs in the application produces a conviction of mind, which is a kind of medium between Philoſophical or ſcientific knowledge, and that which is hiſtorical only.

If we conſider the difference there is between natural philoſophers, and other men, with regard to their knowledge of phenomena, we ſhall find it conſiſts not in an exacter knowledge of the efficient cauſe that produces them, for that can be no other than the will of the Deity; but only in a greater and more enlarged comprehenſion, by which analogies, harmonies, and agreements are deſcribed in the works of nature, and the particular effects explained; that is, reduced to general rules, which rules grounded on the analogy and uniformneſs obſerved in the production of natural effects, are more agreeable, and ſought after by the mind; for that they extend our proſpect beyond what is preſent, and near to us, and enable us to make very probable conjectures, touching things that may have happened at very great diſtances of time and place, as well as to predict things to come; which ſort of endeavour towards omniſcience is much affected by the mind. Berkley, Princip. of Hum. Knowledge, ſect. 104, 105.

From the firſt broachers of new opinions, and the firſt founders of ſchools, Philoſophy is become divided into ſeveral ſects, ſome ancient, others modern; ſuch are the Platoniſts, Peripatetics, Epicureans, Stoics, Pyrrhonians, and Academics; alſo the Carteſians, Newtonians, &c. See the particular articles for each.

Philoſophy may be divided into two branches, or it may be conſidered under two circumſtances, theoretical and practical.

Theoretical or *Speculative* PHILOSOPHY, is employed in mere contemplation. Such is phyſics, which is a bare contemplation of nature, and natural things.

Theoretical Philoſophy again is uſually ſubdivided into three kinds, viz, pneumatics, phyſics or ſomatics, and metaphyſics or ontology.

The firſt conſiders being, abſtractedly from all matter: its objects are ſpirits, their natures, properties, and effects. The ſecond conſiders matter, and material things: its objects are bodies, their properties, laws, &c.

The third extends to each indifferently: its objects are body or ſpirit.

In the order of our diſcovery, or arrival at the knowledge of them, phyſics is firſt, then metaphyſics; the laſt ariſes from the two firſt conſidered together.

But in teaching, or laying down theſe ſeveral branches to others, we obſerve a contrary order; beginning with the moſt univerſal, and deſcending to the more particular. And hence we ſee why the Peripatetics call metaphyſics, and the Carteſians pneumatics, the *prima philoſophia*.

Others prefer the diſtribution of Philoſophy into four parts, viz, 1. Pneumatics, which conſiders and treats of ſpirits. 2. Somatics, of bodies. 3. The third compounded of both, anthropology, which conſiders man, in whom both body and ſpirit are found. 4. Ontoſophy, which treats of what is common to all the other three.

Again, Philoſophy may be divided into three parts; intellectual, moral, and phyſical: the intellectual part compriſes logic and metaphyſics; the moral part contains the laws of nature and nations, ethics and politics; and laſtly the phyſical part comprehends the doctrine of bodies, animate or inanimate: theſe, with their various ſubdiviſions, will comprize the whole of Philoſophy.

Practical PHILOSOPHY, is that which lays down the rules of a virtuous and happy life; and excites us to the practice of them. Moſt authors divide it into two kinds, anſwerable to the two ſorts of human actions to be directed by it; viz, Logic, which governs the operations of the underſtanding; and Ethics, properly ſo called, which direct thoſe of the will.

For the ſeveral particular ſorts of Philoſophy, ſee the articles, Arabian, Ariſtotelian, Atomical, Carteſian, Corpuſcular, Epicurean, Experimental, Hermetical, Leibnitzian, Mechanical, Moral, Natural, Newtonian, Oriental, Platonic, Scholaſtic, Socratic, &c. &c.

PHOENIX, a conſtellation of the ſouthern hemiſphere. This is one of the new-added aſteriſms, unknown to the Ancients, and is not viſible in our northern parts of the globe. There are 13 ſtars in this conſtellation.

PHONICS, otherwiſe called ACOUSTICS, is the doctrine or ſcience of ſounds.

Phonics may be conſidered as an art analogous to Optics; and may be divided, like that, into Direct, Refracted, and Reflected. Theſe branches, the biſhop of Ferns, in alluſion to the parts of Optics, denominates Phonics, Diaphonics, and Cataphonics. See ACOUSTICS.

PHOSPHORUS, a matter which ſhines, or even burns ſpontaneouſly, and without the application of any ſenſible fire.

Phoſphori are either natural or artificial.

Natural PHOSPHORI, are matters which become luminous at certain times, without the aſſiſtance of any art or preparation. Such are the glow-worms, frequent in our colder countries; lantern-flies, and other ſhining inſects, in hot countries; rotten-wood; the eyes, blood, ſcales, fleſh, ſweat, feathers, &c, of ſeveral animals; diamonds, when rubbed after a certain manner, or after having been expoſed to the ſun or light; ſugar and ſulphur, when pounded in a dark place; ſea water, and ſome mineral waters, when briſkly agitated; a cat's or horſe's back, duly rubbed with the hand, &c, in the dark; nay Dr. Croon tells us, that upon rubbing his own body briſkly with a well-warmed ſhirt, he has frequently made both to ſhine; and Dr. Sloane adds, that he knew a gentleman of Briſtol, and his ſon, both whoſe ſtockings would ſhine much after walking.

All natural Phoſphori have this in common, that they do not ſhine always, and that they never give any heat.

Of all the natural Phoſphori, that which has occaſioned the greateſt ſpeculation, is the

Barometrical or *Mercurial* PHOSPHORUS. M. Picard firſt obſerved, that the mercury of his barometer, when ſhaken in a dark place, emitted light. And many fanciful explanations have been given of this phenomenon, which however is now found to be a mere electrical effect.

Mr. Hawkſbee has ſeveral experiments on this appearance. Paſſing air forcibly through the body of quickſilver, placed in an exhauſted receiver, the parts were violently driven againſt the ſide of the receiver, and gave all around the appearance of fire; continuing thus till the receiver was half full again of air.

From other experiments he found, that though the appearance of light was not producible by agitating the mercury in the ſame manner in the common air, yet that a very fine medium, nearly approaching to a vacuum, was not at all neceſſary. And laſtly, from other experiments he found that mercury incloſed in water, which communicated with the open air, by a violent ſhaking of the veſſel in which it was incloſed, emitted particles of light in great plenty, like little ſtars.

By including the veſſel of mercury, &c, in a receiver, and exhauſting the air, the phenomenon was changed; and upon ſhaking the veſſel, inſtead of ſparks of light, the whole maſs appeared one continued circle of light.

Farther, if mercury be incloſed in a glaſs tube, cloſe ſtopped, that tube is found, on being rubbed, to give much more light, than when it had no mercury in it. When this tube has been rubbed, after raiſing ſucceſſively its extremities, that the mercury might flow from one end to the other, a light is ſeen creeping in a ſerpentine manner all along the tube, the mercury being all luminous. By making the mercury run along the tube afterwards without rubbing it, it emitted ſome light, though much leſs than before; this proves that the friction of the mercury againſt the glaſs, in running along, does in ſome meaſure electrify the glaſs, as the rubbing it with the hand does, only in a much leſs degree. This is more plainly proved by laying ſome very light down near the tube, for this will be attracted by the electricity raiſed by the running of the mercury, and will riſe to that part of the glaſs along which the mercury runs; from which it is plain, that what has been long known in the world under the name of the Phoſphorus of the barometer, is not a Phoſphorus, but merely a light raiſed by electricity, the mercury electrifying the tube. Philoſ. Tranſ. numb. 484.

Artificial PHOSPHORI, are ſuch as owe their luminous quality to ſome art or preparation. Some of theſe are made by the maceration of plants alone, and without any fire; ſuch as thread, linen cloth, but above all paper: the luminous appearance of this laſt, which it is now known is an electrical phenomenon, is greatly increaſed by heat. Almoſt all bodies, by a proper treatment, have that power of ſhining in the dark, which at firſt was ſuppoſed to be the property of one, and afterwards only of a few. See Philoſ. Tranſ. numb. 478, in vol. 44, pa. 83.

Of Artificial Phoſphori there are three principal kinds; the firſt *burning*, which conſumes every combuſtible it touches; the other two have no ſenſible heat, and are called the *Bononian* and *Hermetic* Phoſphorus; to which claſs others of a ſimilar kind may be referred.

The Burning PHOSPHORUS, is a combination of phlogiſton with a peculiar acid, and conſequently a ſpecies of ſulphur, tending to decompoſe itſelf, and ſo as to take fire on the acceſs of air only. This may be made of urine, blood, hairs, and generally of any part of an animal that yields an oil by diſtillation, and moſt eaſily of urine. It is of a yellowiſh colour, and of the conſiſtence of hard wax, in the condition it is left by the diſtillation; in which ſtate it is called *phoſphorus fulgurans*, from its corruſcations; and *phoſphorus ſmaragdinus*, becauſe its light is often green or blue, eſpecially in places that are not very dark; and from its conſiſtence it is called ſolid Phoſphorus. It diſſolves in all kinds of diſtilled oils, in which ſtate it is called liquid Phoſphorus. And it may be ground in all kinds of fat pomatums, in which way it makes a luminous unguent.—So that theſe ſorts are all the ſame preparation, under different circumſtances.

The diſcovery of this Phoſphorus was made in 1677, by one Brandt, a citizen of Hamburgh, in his reſearches for the philoſopher's ſtone. And the method was afterwards found out both by Kunckel, and Mr. Boyle, from only learning that urine was the chief ſub-

ſtance

ſtance of it; ſince then it has been called Kunckell's Phoſphorus. It is prepared by firſt evaporating the urine to a rob, or the conſiſtence of honey, and afterwards diſtilling it in a very ſtrong heat, &c. See Mem. Acad. Paris 1737; Philoſ. Tranſ. numb. 196, or Abr. vol. 3, pa. 346; Mem. Acad. Berlin 1743.

Many curious and amuſing experiments are made with Phoſphorus; as by writing with it, when the letters will appear like flame in the dark, though in the light nothing appears but a dim ſmoke; alſo a little bit of it rubbed between two papers, preſently takes fire, and burns vehemently; &c. By waſhing the face, or hands, &c, with liquid Phoſphorus, they will ſhine very conſiderably in the dark, and the luſtre will be communicated to adjacent objects, yet, without hurting the ſkin: on bringing in the candle, the ſhining diſappears, and no change is perceivable.

Bolognian or *Bononian* PHOSPHORUS, is a preparation of a ſtone called the Bononian ſtone, from Bologna, a city in Italy, near which it is found. This Phoſphorus has no ſenſible heat, and only becomes luminous after being expoſed to the ſun or day light. For the method of preparing it, ſee the Mem. Acad. Berlin 1749 and 1750.

The *Hermetic* PHOSPHORUS, or third kind, is a preparation of Engliſh chalk, with aqua fortis, or ſpirit of nitre, by the fire. It makes a body conſiderably ſofter than the Bolognian ſtone, but having otherwiſe all the ſame qualities. It is alſo called Baldwin's Phoſphorus, from its inventor, a German chemiſt, called alſo Hermes in the ſociety of the Naturæ Curioſorum, whence its other name Hermetic: it was diſcovered a little before the year 1677. See Acad. Par. 1693, pa. 271; and Grew's Muſ. Reg. Soc. p. 353.

Ammoniacal PHOSPHORUS, firſt diſcovered by Homberg, is a combination of quick-lime with the acid of ſal ammoniac, from which it receives its phlogiſton. Mem. Acad. Par. 1693.

Antimonial PHOSPHORUS, is a kind diſcovered by Mr. Geoffroy in his experiments on antimony. Mem. Acad. Par. 1736.

PHOSPHORUS *of the Berne-ſtone*, a name given to a ſtone from Berne, in Switzerland, where it is found, and which becomes a kind of Phoſphorus when heated. Mem. Acad. Paris 1724.

Canton's PHOSPHORUS, a very good kind, prepared by Mr. Canton, an ingenious philoſopher, from calcined oyſter ſhells. Philoſ. Tranſ. vol. 58, pa. 337.

PHOPSHORUS *Fœcalis*, a very good kind, exhibiting many wonderful phenomena, and prepared, by Mr. Homberg, from human dung mixed with alum. Mem. Acad. Par. 1711.

PHOSPHORUS *Metallorum*, a name given by ſome chemiſts to a preparation of a certain mineral ſpar, found in the mines of Saxony, and other places where there is copper. Philoſ. Tranſ. numb. 244, p. 365.

PHOSPHORUS *of Sulphur*, a new-diſcovered ſpecies, which readily takes fire on being expoſed to the open air, and invented by M. Le Fevre. Mem. Acad. Par. 1728.

PHOSPHORUS, in Aſtronomy, is the morning ſtar, or the planet Venus, when ſhe riſes before the ſun. The Latins call it Lucifer, the French Etoile de berger, and the Greeks Phoſphorus.

PHYSICAL, ſomething belonging to nature, or exiſting in it. Thus, we ſay a Phyſical point, in oppoſition to a mathematical one, which laſt only exiſts in the imagination. Or a Phyſical ſubſtance or body, in oppoſition to ſpirit, or metaphyſical ſubſtance, &c.

PHYSICAL, or *Senſible Horizon*. See HORIZON.

PHYSICO-*Mathematics*, or *Mixed Mathematics*, includes thoſe branches of Phyſics which, uniting obſervation and experiment to mathematical calculation, explain mathematically the phenomena of nature.

PHYSICS, called alſo *Phyſiology*, and *Natural Philoſophy*, is the doctrine of natural bodies, their phenomena, cauſes, and effects, with their various affections, motions, operations, &c. So that the immediate and proper objects of Phyſics, are body, ſpace, and motion.

The origin of Phyſics is referred, by the Greeks, to the Barbarians, viz, the brachmans, the magi, and the Hebrew and Egyptian prieſts. From theſe it paſſed to the Greek ſages or ſophi, particularly to Thales, who it is ſaid firſt profeſſed the ſtudy of nature in Greece. Hence it deſcended into the ſchools of the Pythagoreans, the Platoniſts, and the Peripatetics; from whence it paſſed into Italy, and thence through the reſt of Europe. Though the druids, bards, &c, had a kind of ſyſtem of Phyſics of their own.

Phyſics may be divided, with regard to the manner in which it has been handled, and the perſons by whom, into

Symbolical PHYSICS, or ſuch as was couched under ſymbols: ſuch was that of the old Egyptians, Pythagoreans, and Platoniſts; who delivered the properties of natural bodies under arithmetical and geometrical characters, and hieroglyphics.

Peripatetical PHYSICS, or that of the Ariſtotelians, who explained the nature of things by matter, form, and privation, elementary and occult qualities, ſympathies, antipathies, attractions, &c.

Experimental PHYSICS, which enquires into the reaſons and natures of things from experiments: ſuch as thoſe in chemiſtry, hydroſtatics, pneumatics, optics, &c. And

Mechanical or *Corpuſcular* PHYSICS, which explains the appearances of nature from the matter, motion, ſtructure, and figure of bodies and their parts: all according to the ſettled laws of nature and mechanics. See each of theſe articles under its own head.

PIASTER, a Spaniſh money, more uſually called Piece of Eight, about the value of 4s. 6d.

PIAZZA, popularly called Piache, an Italian name for a portico, or covered walk, ſupported by arches.

PICARD (JOHN), an able mathematician of France, and one of the moſt learned aſtronomers of the 17th century, was born at Fleche, and became prieſt and prior of Rillie in Anjou. Coming afterwards to Paris, his ſuperior talents for mathematics and aſtronomy ſoon made him known and reſpected. In 1666 he was appointed aſtronomer in the Academy of Sciences. And five years after, he was ſent, by order of the king, to the caſtle of Uraniburgh, built by Tycho Brahe in Denmark, to make aſtronomical obſervations there; and from thence he brought the original manuſcripts, written by Tycho Brahe; which are the more valuable, as they differ in many places from the printed copies, and

contain

contain a book more than has yet appeared. Theſe diſcoveries were followed by many others, particularly in aſtronomy: He was one of the firſt who applied the teleſcope to aſtronomical quadrants: he firſt executed the work called, *La Connoiſſance des Temps*, which he calculated from 1679 to 1683 inclusively: he firſt obſerved the light in the vacuum of the barometer, or the mercurial phoſphorus: he alſo firſt of any went through ſeveral parts of France, to meaſure the degrees of the French meridian, and firſt gave a chart of the country, which the Caſſinis afterwards carried to a great degree of perfection. He died in 1682 or 1683, leaving a name dear to his friends, and reſpectable to his contemporaries and to poſterity. His works are,

1. A treatiſe on Levelling.
2. Practical Dialling by calculation.
3. Fragments of Dioptrics.
4. Experiments on Running Water.
5. Of Meaſurements.
6. Menſuration of Fluids and Solids.
7. Abridgment of the Meaſure of the Earth.
8. Journey to Uraniburgh, or Aſtronomical Obſervations made in Denmark.
9. Aſtronomical Obſervations made in divers parts of France.
10. La Connoiſſance des Temps, from 1679 to 1683.

All theſe, and ſome other of his works, which are much eſteemed, are given in the 6th and 7th volumes of the Memoirs of the Academy of Sciences.

PICCOLOMINI (Alexander), archbiſhop of Patras, and a native of Sienna, where he was born about the year 1508. He was of an illuſtrious and ancient family, which came originally from Rome, but afterwards ſettled at Sienna. He compoſed with ſucceſs for the theatre; but he was not more diſtinguiſhed by his genius, than by the purity of his manners, and his regard to virtue. His charity was great; and was chiefly exerted in relieving the neceſſities of men of letters. He was the firſt who made uſe of the Italian language in writing upon philoſophical ſubjects. He died at Sienna the 12th of March 1578, at 70 years of age, leaving behind him a number of works in Italian, on a variety of ſubjects. A particular catalogue of them may be ſeen in the Typographical Dictionary; the principal of which are the following:

1. Various Dramatical pieces.
2. A treatiſe on the Sphere.
3. A Theory of the Planets.
4. Tranſlation of Ariſtotle's Art of Rhetoric and Poetry.
5. A Syſtem of Morality, publiſhed at Venice, 1575, in 4to; tranſlated into French by Peter de Larivey, and printed at Paris, 1581, in 4to.

Theſe, with a variety of other works, prove his extenſive knowledge in natural philoſophy, mathematics, and theology.

Piccolomini (Francis), of the ſame family with the foregoing, was born in 1520, and taught philoſophy with ſucceſs, for the ſpace of 22 years, in the moſt celebrated univerſities of Italy, and afterwards retired to Sienna, where he died, in 1604, at 84 years of age. He was ſo much and ſo generally reſpected, that the city went into mourning on his death.

Piccolomini laboured to revive the doctrine of Plato, and endeavoured alſo to imitate the manners of that philoſopher. He had for his rival the famous James Zabar Alla, whom he excelled in facility of expreſſion and neatneſs of diction; but to whom he was much inferior in point of argument, becauſe he did not examine matters to the bottom as the other did; but paſſed too rapidly from one propoſition to another.

PICKET, *Picquet*, or *Piquet*, in Fortification &c, a ſtake ſharp at one end, and uſually ſhod with iron; uſed in laying out ground, to mark the ſeveral bounds and angles of it. There are alſo larger Pickets, driven into the earth, to hold together faſcines or faggots, in works that are thrown up in haſte. As alſo various ſorts of ſmaller Pickets for divers other uſes.

PIECES, in Artillery, include all ſorts of great guns and mortars; meaning Pieces of ordnance, or of artillery.

PIEDOUCHE, in Architecture, a little ſtand, or pedeſtal, either oblong or ſquare, enriched with mouldings; ſerving to ſupport a buſt, or other little figure; and is more uſually called a bracket pedeſtal.

PIEDROIT, in Architecture, a kind of ſquare pillar, or pier, partly hid within a wall. Differing from the Pilaſter by having no regular baſe nor capital.

Piedroit is alſo uſed for a part of the ſolid wall annexed to a door or window; comprehending the doorpoſt, chambranle, tableau, leaf, &c.

PIER, in Building, denotes a maſs of ſtone, &c, oppoſed by way of fortreſs, againſt the force of the ſea, or a great river, for the ſecurity of ſhips lying in any harbour or haven. Such are the Piers at Dover, or Ramſgate, or Yarmouth, &c.

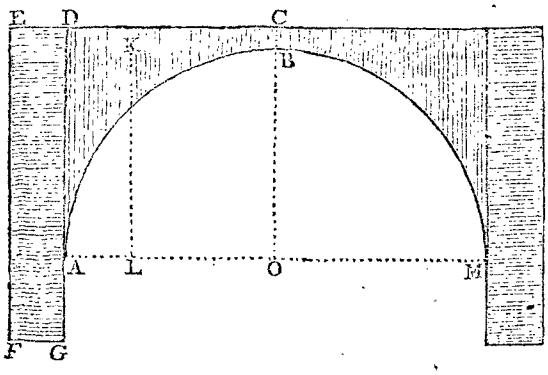
Piers are alſo uſed in Architecture for a kind of pilaſters, or buttreſſes, raiſed for ſupport, ſtrength, and ſometimes for ornament.

Circular Piers, are called Maſſive Columns, and are either with or without caps. Theſe are often ſeen in Saracenic architecture.

Piers, of a Bridge, are the walls built to ſupport the arches, and from which they ſpring as baſes, to ſtand upon.

Piers ſhould be built of large blocks of ſtone, ſolid throughout, and cramped together with iron, which will make the whole as one ſolid ſtone. Their extremities, or ends, from the bottom, or baſe, up to high-water mark, ought to project ſharp out with a ſaliant angle, to divide the ſtream. Or perhaps the bottom part of the Pier ſhould be built flat or ſquare up to about half the height of low-water mark, to encourage a lodgment againſt it for the ſand and mud, to cover the foundation; leſt, being left bare, the water ſhould in time undermine and ruin it. The beſt form of the projection for dividing the ſtream, is the triangle; and the longer it is, or the more acute the ſaliant angle, the better it will divide it, and the leſs will the force of the water be againſt the Pier; but it may be ſufficient to make that angle a right one, as it will render the maſonry ſtronger, and in that caſe the perpendicular projection will be equal to half the breadth or thickneſs of the Pier. In rivers where large heavy craft navigate, and paſs the arches, it may perhaps be better to make the ends ſemicircular; for though this figure does not divide the water ſo well as the triangle, it will better turn off, and bear the ſhock of the craft.

The thickneſs of the Piers ought to be ſuch as will make them of weight, or ſtrength, ſufficient to ſupport their interjacent arch, independent of the aſſiſtance of any other arches. And then, if the middle of the Pier be run up to its full height, the centring may be ſtruck, to be uſed in another arch, before the haunches or ſpandrels are filled up. They ought alſo to be made with a broad bottom on the foundation, and gradually diminiſhed in thickneſs by offsets up to low-water mark.



To find the thickneſs FG *of the Piers*, neceſſary to ſupport an arch ABM, this is a general rule. Let K be the centre of gravity of the half arch ADCB, A = its area; KL perpendicular to AM the ſpan of the arch, OB its height, and BC its thickneſs at the crown: then is the thickneſs of the pier

$$FG = \sqrt{\frac{2GA \times AL}{EF \times KL}} \times A.$$

Some authors pretend to give numbers, in tables, for this purpoſe; but they are very erroneous. See my treatiſe on the Principles of Bridges, ſect. 3.

PIKE, an offenſive weapon, conſiſting of a ſhaft of wood, 12 or 14 feet long, headed with a flat-pointed ſteel, called the ſpear.

Pliny ſays the Lacedemonians were the inventors of the Pike. The Macedonian phalanx was evidently a battalion of Pikemen.

The Pike was long uſed by the infantry, to enable them to ſuſtain the attack of the cavalry; but it is now taken from them, and the bayonet, fixed to the muzzle of the firelock, is given inſtead of it.—It is ſtill uſed by ſome officers of infantry, under the name of ſpontoon.

Half PIKE is the weapon carried by an officer of foot; being only 8 or 9 feet long.

PILASTER, in Architecture, a ſquare column, ſometimes inſulated, but more frequently let within a wall, and only projecting by a 4th or 5th part of its thickneſs.

The Pilaſter is different in the different orders; borrowing the name of each order, and having the ſame proportions, and the ſame capitals, members, and ornaments, with the columns themſelves.

Demi PILASTER, called alſo *Membretto*, is a Pilaſter that ſupports an arch; and it generally ſtands againſt a pier or column.

PILES, in Building, are large ſtakes, or beams, ſharpened at the end, and ſhod with iron, to be driven into the ground, for a foundation to build upon in marſhy places.

Amſterdam, and ſome other cities, are wholly built upon Piles. The ſtoppage of Dagenham-breach was effected by dove-tail Piles, that is by Piles mortiſed into one another by a dovetail joint.

Piles are driven down by blows of a large iron weight, ram, or hammer, dropped continually upon them from a height, till the Pile is ſunk deep enough into the ground.

Notwithſtanding the momentum, or force of a body in motion, is as the weight multiplied by the velocity, or ſimply as its velocity, the weight being given, or conſtant; yet the effect of the blow will be nearly as the ſquare of that velocity, the effect being the quantity the Pile ſinks in the ground by the ſtroke. For the force of the blow, which is transferred to the Pile, being deſtroyed, in ſome certain definite time, by the friction of the part which is within the earth, which is nearly a conſtant quantity; and the ſpaces, in conſtant forces, being as the ſquares of the velocities; therefore the effects, which are thoſe ſpaces ſunk, are nearly as the ſquare of the velocities; or, which is the ſame thing, nearly as the heights fallen by the ram or hammer, to the head of the Pile. See, upon this ſubject, Leopold Belidor, alſo Deſaguliers's Exper. Philoſ. vol. 1, pa. 336, and vol. 2, pa. 417: and Philoſ. Tranſ. 1779, pa. 120.

There have been various contrivances for raiſing and dropping the hammer, for driving down the Piles; ſome ſimple and moved by ſtrength of men, and ſome complex and by machinery; but the completeſt Pile-Driver is eſteemed that which was employed in driving the Piles in the foundation of Weſtminſter bridge. This machine was the invention of a Mr. Vauloue, and the deſcription of it is as follows.

Deſcription of Vauloue's PILE-*Driver*. See fig. 2, pl. xx. A is the great upright ſhaft or axle, carrying the great wheel B and drum C, and turned by horſes attached to the bars S, S. The wheel B turns the trundle X, having a fly O at the top, to regulate the motion, and to act againſt the horſes, and keep them from falling when the heavy ram Q is diſengaged to drive the Pile P down into the mud &c. in the bottom of the river. The drum C is looſe upon the ſhaft A, but is locked to the wheel B by the bolt Y. On this drum the great rope HH is wound; one end of it being fixed to the drum, and the other to the follower G, paſſing over the pulleys I and K. In the follower G are contained the tongs F, which take hold of the ram Q, by the ſtaple R for drawing it up. D is a ſpiral or fuſee fixed to the drum, on which winds the ſmall rope T which goes over the pulley U, under the pulley V, and is faſtened to the top of the frame at 7. To the pulley-block V is hung the counterpoiſe W, which hinders the follower from accelerating as it goes down to take hold of the ram: for, as the follower tends to acquire velocity in its deſcent, the line T winds downwards upon the fuſee, on a larger and larger radius, by which means the counterpoiſe W acts ſtronger and ſtronger againſt it; and ſo allows it to come down with only a moderate and uniform velocity. The bolt Y locks the drum

drum to the great wheel, being puſhed upward by the ſmall lever 2, which goes through a mortiſe in the ſhaft A, turns upon a pin in the bar 3 fixed into the great wheel B, and has a weight 4, which always tends to puſh up the bolt Y through the wheel into the drum. L is the great lever turning on the axis *m*, and reſting upon the forcing bar 5, 5, which goes down through a hollow in the ſhaft A, and bears upon the little lever 2.

By the horſes going round, the great rope H is wound about the drum C, and the ram Q is drawn up by the tongs F in the follower G, till they come between the inclined planes E; which, by ſhutting the tongs at the top, open them below, and ſo diſcharge the ram, which falls down between the guide poſts *bb* upon the Pile P, and drives it by a few ſtrokes as far into the ground as it can go, or as is deſired; after which, the top part is ſawed off cloſe to the mud, by an engine for that purpoſe. Immediately after the ram is diſcharged, the piece 6 upon the follower G takes hold of the ropes *aa*, which raiſe the end of the lever L, and cauſe its end N to deſcend and preſs down the forcing bar 5 upon the little lever 2, which, by drawing down the bolt Y, unlocks the drum C from the great wheel B; and then the follower, being at liberty, comes down by its own weight to the ram; and the lower ends of the tongs ſlip over the ſtaple R, and the weight of their heads cauſes them to fall outward, and ſhuts upon it. Then the weight 4 puſhes up the bolt Y into the drum, which locks it to the great wheel, and ſo the ram is drawn up as before.

As the follower comes down, it cauſes the drum to turn backward, and unwinds the rope from it, while the horſes, the great wheel, trundle, and fly, go on with an uninterrupted motion: and as the drum is turning backward, the counterpoiſe W is drawn up, and its rope T wound upon the ſpiral fuſee D.

There are ſeveral holes in the under ſide of the drum, and the bolt Y always takes the firſt one that it finds when the drum ſtops by the falling of the follower upon the ram; till which ſtoppage, the bolt has not time to ſlip into any of the holes.

The peculiar advantages of this engine are, that the weight, called the ram, or hammer, may be raiſed with the leaſt force; that, when it is raiſed to a proper height, it readily diſengages itſelf and falls with the utmoſt freedom; that the forceps or tongs are lowered down ſpeedily, and inſtantly of themſelves again lay hold of the ram, and lift it up; on which account this machine will drive the greateſt number of piles in the leaſt time, and with the feweſt labourers.

This engine was placed upon a barge on the water, and ſo was eaſily conveyed to any place deſired. The ram was a ton weight; and the guides *b*, *b*, by which it was let fall, were 30 feet high.

A new machine for driving piles has been invented lately by Mr. S. Bunce of Kirby-ſtreet, Hatton-ſtreet, London. This, it is ſaid, will drive a greater number of Piles in a given time than any other; and that it can be conſtructed more ſimply to work by horſes than Vauloue's engine above deſcribed.

Fig. 3 and 4, plate xx, repreſent a ſide and front ſection of the machine. The chief parts are, A, fig. 3, which are two endleſs ropes or chains, connected by croſs pieces of iron B (fig. 4) correſponding with two croſs grooves cut diametrically oppoſite in the wheel C (fig. 3) into which they are received; and by which means the rope or chain A is carried round. FHK is a ſide-view of a ſtrong wooden frame moveable on the axis H. D is a wheel, over which the chain paſſes and turns within at the top of the frame. It moves occaſionally from F to G upon the centre H, and is kept in the poſition F by the weight I fixed to the end K. In fig. 5, L is the iron ram, which is connected with the croſs pieces by the hook M. N is a cylindrical piece of wood ſuſpended at the hook at O, which by ſliding freely upon the bar that connects the hook to the ram, always brings the hook upright upon the chain when at the bottom of the machine, in the poſition of GP. See fig. 3.

When the man at S turns the uſual crane-work, the ram being connected to the chain, and paſſing between the guides, is drawn up in a perpendicular direction; and when it is near the top of the machine, the projecting bar Q of the hook ſtrikes againſt a croſs piece of wood at R (fig. 3); and conſequently diſcharges the ram, while the weight I of the moveable frame inſtantly draws the upper wheel into the poſition ſhewn at F, and keeps the chain free of the ram in its deſcent. The hook, while deſcending, is prevented from catching the chain by the wooden piece N: for that piece being ſpecifically lighter than the iron weight below, and moving with a leſs degree of velocity, cannot come into contact with the iron, till it is at the bottom, and the ram ſtops. It then falls, and again connects the hook with the chain, which draws up the ram, as before.

Mr. Bunce has made a model of this machine, which performs perfectly well; and he obſerves, that, as the motion of the wheel C is uninterrupted, there appears to be the leaſt poſſible time loſt in the operation.

PILE is alſo uſed among Architects, for a maſs or body of building.

PILE, in Artillery, denotes a collection or heap of ſhot or ſhells, piled up by horizontal courſes into either a pyramidal or elſe a wedge-like form; the baſe being an equilateral triangle, a ſquare, or a rectangle. In the triangle and ſquare, the Pile terminates in a ſingle ball or point, and forms a pyramid, as in plate xix, fig. 4 and 5, but with the rectangular baſe, it finiſhes at top in a row of balls, or an edge, forming a wedge, as in fig. 6.

In the triangular and ſquare Piles, the number of horizontal rows, or courſes, or the number counted on one of the angles from the bottom to the top, is always equal to the number counted on one ſide, in the bottom row. And in rectangular Piles, the number of rows, or courſes, is equal to the number of balls in the breadth of the bottom row, or ſhorter ſide of the baſe: alſo, in this caſe, the number in the top row, or edge, is one more than the difference between the length and breadth of the baſe. All which is evident from the inſpection of the figures, as above.

The courſes in theſe Piles are figurate numbers.

In a triangular Pile, each horizontal courſe is a triangular number, produced by taking the ſucceſſive ſums of the ordinate numbers, viz,

$$1 = 1$$
$$1 + 2 = 3$$
$$1 + 2 + 3 = 6$$
$$1 + 2 + 3 + 4 = 10, \text{ \&c.}$$

And

And the number of ſhot in the triangular Pile, is the ſum of all theſe triangular numbers, taken as far, or to as many terms, as the number in one ſide of the baſe. And therefore, to find this ſum, or the number of all the ſhot in the Pile, multiply continually together, the number in one ſide of the baſe row, and that number increaſed by 1, and the ſame number increaſed by 2; then $\frac{1}{6}$ of the laſt product will be the anſwer, or number of all the ſhot in the Pile.

That is, $\frac{n \cdot n + 1 \cdot n + 2}{6}$ is the ſum;

where n is the number in the bottom row.

Again, in Square Piles, each horizontal courſe is a ſquare number, produced by taking the ſquare of the number in its ſide, or the ſucceſſive ſums of the odd numbers, thus,

$1 = 1$
$1 + 3 = 4$
$1 + 3 + 5 = 9$
$1 + 3 + 5 + 7 = 16$, &c.

And the number of ſhot in the ſquare Pile is the ſum of all theſe ſquare numbers, continued ſo far, or to as many terms, as the number in one ſide of the baſe. And therefore, to find this ſum, multiply continually together, the number in one ſide of the bottom courſe, and that number increaſed by 1, and double the ſame number increaſed by 1; then $\frac{1}{6}$ of the laſt product will be the ſum or anſwer.

That is, $\frac{n \cdot n + 1 \cdot 2n + 1}{6}$ is the ſum.

In a rectangular Pile, each horizontal courſe is a rectangle, whoſe two ſides have always the ſame difference as thoſe of the baſe courſe, and the breadth of the top row, or edge, being only 1: becauſe each courſe in aſcending has its length and breadth always leſs by 1 than the courſe next below it. And theſe rectangular courſes are found by multiplying ſucceſſively the terms or breadths 1, 2, 3, 4, &c, by the ſame terms added to the conſtant difference of the two ſides d; thus,

$1 \cdot 1 + d = 1 + d$
$2 \cdot 2 + d = 4 + 2d$
$3 \cdot 3 + d = 9 + 3d$
$4 \cdot 4 + d = 16 + 4d$, &c.

And the number of ſhot in the rectangular Pile is the ſum of all theſe rectangles, which, it is evident, conſiſt of the ſum of the ſquares, together with the ſum of an arithmetical progreſſion, continued till the number of terms be the difference between the length and breadth of the baſe, and 1 leſs than the edge or top row. And therefore, to find this ſum, multiply continually together, the number in the breadth of the baſe row, the ſame number increaſed by 1, and double the ſame number increaſed by 1, and alſo increaſed by triple the difference between the length and breadth of the baſe; then $\frac{1}{6}$ of the laſt product will be the anſwer.

That is, $\frac{b \cdot b + 1 \cdot 2b + 3d + 1}{6}$ is the ſum.

where b is the breadth of the baſe, and d the difference between the length and breadth of the bottom courſe.

As to incomplete Piles, which are only fruſtums, wanting a ſimilar ſmall Pile at the top; it is evident that the number in them will be found, by firſt computing the number in the whole Pile, as if it were complete, and alſo the number in the ſmall Pile wanting at top, both by their proper rule; and then ſubtracting the one number from the other.

In piling of ſhot, when room is an object, it may be obſerved that the ſquare Pile is the leaſt eligible, of any, as it takes up more room, in proportion to the number of ſhot contained in it, than either of the other two forms; and that the rectangular Pile is the moſt eligible, as taking up the leaſt room in proportion to the number it contains.

PILLAR, a kind of irregular column, round, and inſulated, or detached from the wall. Pillars are not reſtricted to any rules, their parts and proportions being arbitrary; ſuch for example as thoſe that ſupport Saracenic vaults, and other buildings, &c.

PINION, in Mechanics, is an arbor, or ſpindle, in the body of which are ſeveral notches, which are catched by the teeth of a wheel that ſerves to turn it round. Or a Pinion is any leſſer wheel that plays in the teeth of a larger.

In a watch, &c, the notches of a Pinion are called leaves, and not teeth, as in other wheels; and their number is commonly 4, 5, 6, 8, &c.

PINION *of Report*, is that Pinion, in a watch, commonly fixed on the arbor of a great wheel: and which uſed to have but four leaves in old watches; it drives the dial-wheel, and carries about the hand.

The number of turns to be laid upon the Pinion of report, is found by this proportion: as the beats in one turn of the great wheel, are to the beats in an hour, ſo are the hours on the face of the clock (viz 12 or 24), to the quotient of the hour-wheel or dial-wheel divided by the Pinion of report, that is, by the number of turns which the Pinion of report hath in one turn of the dial-wheel. Which in numbers is 26928 : 20196 :: 12 : 9. —Or thus; as the hours of the watch's going, are to the numbers of the turns of the fuſee, ſo are the hours of the face, to the quotient of the Pinion of report. So, if the hours be 12, then as 16 : 12 :: 12 : 9; but if 24, then as 16 : 12 :: 24 : 18.

This rule may ſerve to lay the Pinion of report on any other wheel, thus: as the beats in one turn of any wheel, are to the beats in an hour, ſo are the hours of the face, or dial-plate, of the watch, to the quotient of the dial-wheel divided by the Pinion of report, fixed on the ſpindle of the aforeſaid wheel.

PINT, a meaſure of capacity, being the 8th part of a gallon, both in ale and wine meaſure, &c. The wine Pint of pure ſpring water, weighs near 17 ounces avoirdupois, and the ale Pint a little above 20 ounces.

The Paris Pint contains about 2 pounds of common water. And the Scotch Pint contains 108$\frac{2}{3}$ cubic inches, and therefore contains 3 Engliſh Pints.

PISCES, the 12th ſign or conſtellation in the zodiac; in the form of two fiſhes tied together by the tails.

The Greeks, who have ſome fable to account for the origin of every conſtellation, tell us, that when Venus and Cupid were one time on the banks of the Euphrates, there appeared before them that terrible giant Typhon, who was ſo long a terror to all the Gods. Theſe deities immediately, they ſay, threw themſelves into

into the water, and were there changed into theſe two fiſhes, the Piſces, by which they eſcaped the danger. But the Egyptians uſed the ſigns of the zodiac as part of their hieroglyphic language, and by the 12 they conveyed an idea of the proper employment during the 12 months of the year. The Ram and the Bull had, at that time, taken to the increaſe of their flock, the young of thoſe animals being then growing up; the maid Virgo, a reaper in the field, ſpoke the approach of harveſt; Sagittary declared autumn the time for hunting; and the Piſces, or fiſhes tied together, in token of their being taken, reminded men that the approach of ſpring was the time for fiſhing.

The Ancients, as they gave one of the 12 months of the year to the patronage of each of the 12 ſuperior deities, ſo they alſo dedicated to, or put under the tutelage of each, one of the 12 ſigns of the zodiac. In this diviſion, the fiſhes naturally fell to the ſhare of Neptune; and hence ariſes that rule of the aſtrologers, which throws every thing that regards the fate of fleets and merchandize, under the more immediate patronage and protection of this conſtellation.

The ſtars in the ſign Piſces are, in Ptolomy's catalogue 38, in Tycho's 36, in Hevelius's 39, and in the Britannic catalogue 113.

PISCIS *Auſtralis*, the Southern Fiſh, is a conſtellation of the ſouthern hemiſphere, being one of the old 48 conſtellations mentioned by the Ancients.

The Greeks have here again the fable of Venus and her ſon throwing themſelves into the ſea, to eſcape from the terrible Typhon. This fable is probably borrowed from the hieroglyphics of the Egyptians. With them, a fiſh repreſented the ſea, its element; and Typhon was probably a land flood, perhaps repreſented by the ſign Aquarius, or water pourer, whoſe ſtream or river is repreſented as ſwallowed up by this fiſh, as the land floods and rivers are by the ſea. And Venus was ſome queen, perhaps Semiramis, otherwiſe called Hamamah, who took to the river or the ſea with her ſon, in a veſſel, to avoid the flood, &c.

The remarkable ſtar Fomahaut, of the 1ſt magnitude, is juſt in the mouth of this fiſh. The ſtars of this conſtellation are, in Ptolomy's catalogue 18, and in Flamſteed's 24.

PISCIS *Volans*, the Flying Fiſh, is a ſmall conſtellation of the ſouthern hemiſphere, unknown to the Ancients, but added by the Moderns. It is not viſible in our latitude, and contains only 8 ſtars.

PISTOLE, a gold coin in Spain, Italy, Switzerland, &c, of the value of about 16s. 6d.

PISTON, a part or member in ſeveral machines, particularly pumps, air-pumps, ſyringes, &c; called alſo the Embolus, and popularly the Sucker.

The Piſton of a pump is a ſhort cylinder of wood or metal, fitted exactly to the cavity of the barrel, or body; and which, being worked up and down alternately, raiſes the water; and when raiſed, preſſes it again, ſo as to make it force up a valve with which it is furniſhed, and ſo eſcape through the ſpout of the pump.

There are two ſorts of Piſtons uſed in pumps; the one with a valve, called a bucket; and the other without a valve, called a forcer.

PLACE, in Philoſophy, that part of infinite ſpace which any body poſſeſſes.

Ariſtotle and his followers divide Place into External and Internal.

Internal PLACE, is that ſpace or room which the body contains. And

External PLACE, is that which includes or contains the body; and is by Ariſtotle called the firſt or concave and immoveable ſurface of the ambient body.

Newton better, and more intelligibly, diſtinguiſhes Place into Abſolute and Relative.

Abſolute and *Primary* PLACE, is that part of infinite and immoveable ſpace which a body poſſeſſes. And

Relative, or *Secondary* PLACE, is the ſpace it poſſeſſes conſidered with regard to other adjacent objects.

Dr. Clark adds another kind of Relative Place, which he calls Relatively Common Place; and defines it, that part of any moveable or meaſurable ſpace which a body poſſeſſes; which Place moves together with the body.

PLACE, Mr. Locke obſerves, is ſometimes likewiſe taken for that portion of infinite ſpace poſſeſſed by the material world; though this, he adds, were more properly called extenſion. The proper idea of Place, according to him, is the relative poſition of any thing, with regard to its diſtance from certain fixed points; whence it is ſaid a thing has or has not changed Place, when its diſtance is or is not altered with reſpect to thoſe bodies.

PLACE, in Optics, or *Optical* PLACE, is the point to which the eye refers an object.

Optic PLACE of a ſtar, is a point in the ſurface of the mundane ſphere in which a ſpectator ſees the centre of the ſtar, &c.—This is divided into True and Apparent.

True, or *Real Optic* PLACE, is that point of the ſurface of the ſphere, where a ſpectator at the centre of the earth would ſee the ſtar, &c.

Apparent, or *Viſible Optic* PLACE, is that point of the ſurface of the ſphere, where a ſpectator at the ſurface of the earth ſees the ſtar, &c.

The diſtance between theſe two optic Places makes what is called the Parallax.

PLACE *of the Sun*, or *Moon*, or *Star*, or *Planet*, in Aſtronomy, ſimply denotes the ſign and degree of the zodiac which the luminary is in; and is uſually expreſſed either by its latitude and longitude, or by its right aſcenſion and declination.

PLACE *of Radiation*, in Optics, is the interval or ſpace in a medium, or tranſparent body, through which any viſible object radiates.

PLACE, in Geometry, uſually called *Locus*, is a line uſed in the ſolution of problems, being that in which the determination of every caſe of the problem lies. See LOCUS, *Plane*, *Simple*, *Solid*, &c.

PLACE, in War and Fortification, a general name for all kinds of fortreſſes, where a party may defend themſelves.

PLACE *of Arms*, a ſtrong part where the arms &c are depoſited, and where uſually the ſoldiers aſſemble and are drawn up.

PLAFOND, or PLATFOND, in Architecture, the cieling of a room.

PLAIN &c. See PLANE.

PLAN, a repreſentation of ſomething, drawn on a plane. Such as maps, charts, and ichnographies.

PLAN, in Architecture, is particularly uſed for a draught of a building; ſuch as it appears, or is intended to appear, on the ground; ſhewing the extent, diviſion, and diſtribution of its area into apartments, rooms, paſſages, &c. It is alſo called the Ground Plot, Platform, and Ichnography of the building; and is the firſt device or ſketch the architect makes.

Geometrical PLAN, is that in which the ſolid and vacant parts are repreſented in their natural proportion.

Raiſed PLAN, is that where the elevation, or upright, is ſhewn upon the geometrical Plan, ſo as to hide the diſtribution.

Perſpective PLAN, is that which is conducted and exhibited by degradations, or diminutions, according to the rules of Perſpective.

PLANE, or PLAIN, in Geometry, denotes a Plane figure, or a ſurface lying evenly between its bounding lines. Euclid.

Some define a Plane, a ſurface, from every point of whoſe perimeter a right line may be drawn to every other point in the ſame, and always coinciding with it.

As the right line is the ſhorteſt extent from one point to another, ſo is a Plane the ſhorteſt extenſion between one line and another.

PLANES are much uſed in Aſtronomy, conic ſections, ſpherics, &c, for imaginary ſurfaces, ſuppoſed to cut and paſs through ſolid bodies.

When a Plane cuts a cone parallel to one ſide, it makes a parabola; when it cuts the cone obliquely, an ellipſe or hyperbola; and when parallel to its baſe, a circle. Every ſection of a ſphere is a circle.

The ſphere is wholly explained by Planes, conceived to cut the celeſtial bodies, and to fill the areas or circumferences of the orbits. They are differently inclined to each other; and by us the inhabitants of the earth, the Plane of whoſe orbit is the Plane of the ecliptic, their inclination is eſtimated with regard to this Plane.

PLANE *of a Dial*, is the ſurface on which a dial is ſuppoſed to be deſcribed.

PLANE, in Mechanics. A *Horizontal* PLANE, is a Plane that is level, or parallel to the horizon.

Inclined PLANE, is one that makes an oblique angle with a horizontal Plane.

The doctrine of the motion of bodies on Inclined Planes, makes a very conſiderable article in mechanics, and has been fully explained under the articles, MECHANICAL *Powers*, and INCLINED *Plane*.

PLANE *of Gravity*, or *Gravitation*, is a Plane ſuppoſed to paſs through the centre of gravity of the body, and in the direction of its tendency; that is, perpendicular to the horizon.

PLANE *of Reflection*, in Catoptrics, is a Plane which paſſes through the point of reflection; and is perpendicular to the Plane of the glaſs, or reflecting body.

PLANE *of Refraction*, is a Plane paſſing through the incident and refracted ray.

Perſpective PLANE, is a Plane tranſparent ſurface, uſually perpendicular to the horizon, and placed between the ſpectator's eye and the object he views; through which the optic rays, emitted from the ſeveral points of the object, are ſuppoſed to paſs to the eye, and in their paſſage to leave marks that repreſent them on the ſaid Plane.—Some call this the Table, or Picture, becauſe the draught or Perſpective of the object is ſuppoſed to be upon it. Others call it the Section, from its cutting the viſual rays; and others again the Glaſs, from its ſuppoſed tranſparency.

Geometrical PLANE, in Perſpective, is a Plane parallel to the horizon, upon which the object is ſuppoſed to be placed that is to be drawn.

Horizontal PLANE, in Perſpective, is a Plane paſſing through the ſpectator's eye, parallel to the horizon.

Vertical PLANE, in Perſpective, is a Plane paſſing through the ſpectator's eye, perpendicular to the geometrical Plane, and uſually at right angles to the perſpective Plane.

Objective PLANE, in Perſpective, is any Plane ſituate in the horizontal Plane, of which the repreſentation in perſpective is required.

PLANE *of the Horopter*, in Optics, is a Plane paſſing through the horopter AB, and perpendicular to a Plane paſſing through the two optic axes CH and CI. See the fig. to the article HOROPTER.

PLANE *of the Projection*, is the Plane upon which the ſphere is projected.

PLANE *Angle*, is an angle contained under two lines or ſurfaces.—It is ſo called in contradiſtinction to a ſolid angle, which is formed by three or more Planes.

PLANE *Triangle*, is a triangle formed by three right lines; in oppoſition to a ſpherical and a mixt triangle.

PLANE *Trigonometry* is the doctrine of Plane triangles, their meaſures, proportions, &c. See TRIGONOMETRY.

PLANE *Glaſs*, or *Mirror*, in Optics, is a glaſs or mirror having a flat or even ſurface.

PLANE *Chart*, in Navigation, is a ſea-chart, having the meridians and parallels repreſented by parallel ſtraight lines; and conſequently having the degrees of longitude the ſame in every part. See CHART.

PLANE *Number*, is that which may be produced by the multiplication of two numbers the one by the other. Thus, 6 is a plane number, being produced by the multiplication of the two numbers 2 and 3; alſo 15 is a Plane number, being produced by the multiplication of the numbers 3 and 5. See NUMBER.

PLANE *Place*, *Locus Planus*, or *Locus ad Planum*, is a term uſed by the ancient geometricians, for a geometrical locus, when it was a right line or a circle, in oppoſition to a ſolid place, which was one of the conic ſections.

Theſe Plane Loci are diſtinguiſhed by the Moderns into Loci ad Rectum, and Loci ad Circulum. See LOCUS.

PLANE *Problem*, is ſuch a one as cannot be reſolved geometrically, but by the interſection either of a right line and a circle, or of the circumferences of two circles. Such as this problem following: viz, Given the hypothenuſe, and the ſum of the other two ſides, of a right-angled triangle; to find the triangle. Or this: Of four given lines to form a trapezium of a given area.

PLANE *Sailing*, in Navigation, is the art of working the ſeveral caſes and varieties in a ſhip's motion on a Plane chart; or of navigating a ſhip upon principles

deduced from the notion of the earth's being an extended Plane.

This principle, though notoriouſly falſe, yet places being laid down accordingly, and a long voyage broken into many ſhort ones, the voyage may be performed tolerably well by it, eſpecially near the ſame meridian.

In Plain Sailing it is ſuppoſed that theſe three, the rhumb line, the meridian, and parallel of latitude, will always form a right-angled triangle; and ſo poſited, as that the perpendicular ſide will repreſent part of the meridian, or north and ſouth line, containing the difference of latitude; the baſe of the triangle, the departure, or eaſt-and-weſt line; and the hypothenuſe the diſtance ſailed. The angle at the vertex is the courſe; and the angle at the baſe, the complement of the courſe; any two of which, beſides the right angle, being given, the triangle may be protracted, and the other three parts found.

For the doctrine of Plane Sailing, ſee SAILING.

PLANE *Scale*, is a thin ruler, upon which are graduated the lines of chords, ſines, tangents, ſecants, leagues, rhumbs, &c; being of great uſe in moſt parts of the mathematics, but eſpecially in navigation. See its deſcription and uſe under SCALE.

PLANE *Table*, an inſtrument much uſed in land-ſurveying; by which the draught, or plan, is taken upon the ſpot, as the ſurvey or meaſurement goes on, without any future protraction, or plotting.

This inſtrument conſiſts of a Plane rectangular board, of any convenient ſize, the centre of which, when uſed, is fixed by means of ſcrews to a three-legged ſtand, having a ball and ſocket, or univerſal joint, at the top, by means of which, when the legs are fixed on the ground, the table is inclined in any direction. To the table belongs,

1. A frame of wood, made to fit round its edges, for the purpoſe of fixing a ſheet of paper upon the table. The one ſide of this frame is uſually divided into equal parts, by which to draw lines acroſs the table, parallel or perpendicular to the ſides; and the other ſide of the frame is divided into 360 degrees, from a centre which is in the middle of the table; by means of which the table is to be uſed as a theodolite, &c.

2. A magnetic needle and compaſs ſcrewed into the ſide of the table, to point out directions and be a check upon the ſights.

3. An index, which is a braſs two-foot ſcale, either with a ſmall teleſcope, or open ſights erected perpendicularly upon the ends. Theſe ſights and the fiducial edge of the index are parallel, or in the ſame Plane.

General Uſe of the PLANE *Table.*

To uſe this inſtrument properly, take a ſheet of writing or drawing paper, and wet it to make it expand; then ſpread it flat upon the table, preſſing down the frame upon the edges, to ſtretch it, and keep it fixed there; and when the paper is become dry, it will, by ſhrinking again, ſtretch itſelf ſmooth and flat from any cramps or unevenneſs. Upon this paper is to be drawn the plan or form of the thing meaſured.

The general uſe of this inſtrument, in land-ſurveying, is to begin by ſetting up the table at any part of the ground you think the moſt proper, and make a point upon a convenient part of the paper or table, to repreſent that point of the ground; then fix in that point of the paper one leg of the compaſſes, or a fine ſteel pin, and apply to it the fiducial edge of the index, moving it round the table, cloſe by the pin, till through the ſights you perceive ſome point deſired, or remarkable object, as the corner of a field, or a picket ſet up, &c; and from the ſtation point draw a dry or obſcure line along the fiducial edge of the index. Then turn the index to another object, and draw a line on the paper towards it. Do the ſame by another; and ſo on till as many objects are ſet as may be thought neceſſary. Then meaſure from your ſtation towards as many of the objects as may be neceſſary, and no more, taking the requiſite offſets to corners or crooks in the hedges, &c; laying the meaſured diſtances, from a proper ſcale, down upon the reſpective lines on the paper. Then move the table to any of the proper places meaſured to, for a ſecond ſtation, fixing it there in the original poſition, turning it about its centre for that purpoſe, both till the magnetic needle point to the ſame degree of the compaſs as at firſt, and alſo by laying the fiducial edge of the index along the line between the two ſtations, and turning the table till through the index the former ſtation can be ſeen; and then fix the table there: from this new ſtation repeat the ſame operations as at the former; ſetting ſeveral objects, that is, drawing lines towards them, on the paper, by the edge of the index, meaſuring and laying off the diſtances. And thus proceed from ſtation to ſtation; meaſuring only ſuch lines as are neceſſary, and determining as many as you can by interſecting lines of direction drawn from different ſtations.

Of Shifting the Paper on the PLANE *Table.* When one paper is full of the lines &c meaſured, and the ſurvey is not yet completed; draw a line in any manner through the fartheſt point of the laſt ſtation line to which the work can be conveniently laid down; then take the ſheet off the table, and fix another fair ſheet in its place, drawing a line upon it, in a part of it the moſt convenient for the reſt of the work, to repreſent the line drawn at the end of the work on the former paper. Then fold or cut the old ſheet by the line drawn upon it; apply it ſo to the line on the new ſheet, and, as they lie together in that poſition, continue or produce the laſt ſtation line of the old ſheet upon the new one; and place upon it the remainder of the meaſurement of that line, beginning at where the work left off on the old ſheet. And ſo on, from one ſheet to another, till the whole work is completed.

But it is to be noted, that if the ſaid joining lines, upon the old and new ſheet, have not the ſame inclination to the ſide of the table, the needle will not reſpect or point to the original degree of the compaſs, when the table is rectified. But if the needle be required to reſpect ſtill the ſame degree of the compaſs, the eaſieſt way then of drawing the lines in the ſame poſition, is to draw them both parallel to the ſame ſides of the table, by means of the equal parallel diviſions marked on the other two ſides of the frame.

When the work of ſurveying is done, and you would faſten all the ſheets together into one piece, or rough plan, the aforeſaid lines are to be accurately joined together, in the ſame manner as when the lines were tranſferred from the old ſheets to the new ones.

See more full directions for the uſe of the Plane Table,

Table, illuſtrated with various examples, in my Treatiſe on Menſuration, 2d edit. pa. 509 &c.

PLANET, literally a wanderer, or a wandering ſtar, in oppoſition to a ſtar, properly ſo called, which remains fixed. It is a celeſtial body, revolving around the ſun, or ſome other planet, as a centre, or at leaſt as a focus, and with a moderate degree of excentricity, ſo that it never is ſo much farther from the ſun at one time than at another, but that it can be ſeen as well from one part of its orbit as another; as diſtinguiſhed from the comets, which on the fartheſt part of their trajectory go off to ſuch vaſt diſtances, as to remain a long time inviſible.

The Planets are uſually diſtinguiſhed into Primary and Secondary.

Primary PLANETS, called alſo ſimply Planets, are thoſe which move round the ſun, as their centre, or focus of their orbit. Such as Mercury, Venus, the Earth, Mars, Jupiter, Saturn, the Georgian or Herſchel, and perhaps others. And the

Secondary PLANETS, are ſuch as move round ſome primary one, as their centre, in the ſame manner as the primary ones do about the ſun. Such as the moon, which moves round the earth, as a ſecondary; and the three, Jupiter, Saturn, and Georgian, have each ſeveral ſecondary Planets, or moons, moving round them.

Till very lately the number of the primary Planets was eſteemed only ſix, which it was thought conſtituted the whole number of them in the ſolar ſyſtem; viz, Mercury, Venus, the Earth, Mars, Jupiter, and Saturn; all of which it appears were known to the aſtronomers of all ages, who never dreamt of an increaſe to their number. But a ſeventh has been lately diſcovered, by Dr. Herſchel, viz, on March the 13th, 1781, lying beyond all the reſt, and now called the Georgian, or Herſchel: and poſſibly others may ſtill remain undiſcovered to this day.

The primary Planets are again diſtinguiſhed into Superior and Inferior.

The Superior Planets are thoſe that are above the earth, or farther from the ſun than the earth is; as, Mars, Jupiter, Saturn, and the Georgian or Herſchel. And

The Inferior Planets are thoſe that are below the earth, or that are nearer the ſun than the earth is; which are Venus and Mercury.

The Planets were repreſented by the ſame characters as the chemiſts uſe to repreſent their metals by, on account of ſome ſuppoſed analogy between thoſe celeſtial and the ſubterraneous bodies. Thus,

Mercury, the meſſenger of the Gods, repreſented by ☿, the ſame as that metal, imitating a man with wings on his head and feet, is a ſmall bright planet, with a light tinct of blue, the ſun's conſtant attendant, from whoſe ſide it never departs above 28°, and by that means is uſually hid in his ſplendor. It performs its courſe around him in about 3 months.

Venus, the goddeſs of love, marked ♀, from the figure of a woman, the ſame as denotes copper, from a ſlight tinge of that colour, or verging to a light ſtraw colour. She is a very bright Planet, revolving next above Mercury, and never appears above 48 degrees from the ſun, finiſhing her courſe about him in about ſeven months. When this Planet goes before the ſun, or is a morning ſtar, it has been called Phoſphorus, and alſo Lucifer; and when following him, or when it ſhines in the evening as an evening ſtar, it is called Heſperus.

Tellus, the Earth, next above Venus, is denoted by ⊕, and performs its courſe about the ſun in the ſpace of a year.

Mars, the god of war, characterized ♂, a man holding out a ſpear, the ſame as iron, is a ruddy fiery-coloured Planet, and finiſhes his courſe about the ſun in about 2 years.

Jupiter, the chief god, or thunderer, marked ♃, to repreſent the thunderbolts, denoting the ſame as tin, from his pure white brightneſs. This Planet is next above Mars, and completes its courſe round the ſun in about 12 years.

Saturn, the father of the Gods, is expreſſed by ♄, to imitate an old man ſupporting himſelf with a ſtaff, and is the ſame as denotes lead, from his feeble light and duſky colour. He revolves next above Jupiter, and performs his courſe in about 30 years.

Laſtly, the Georgian, or Herſchel, is denoted by ♅, the initial of his name, with a croſs for the chriſtian Planet, or that diſcovered by the chriſtians. This is the higheſt, or outermoſt, of the known Planets, and revolves around the ſun in the ſpace of about 90 years.

From theſe deſcriptions a perſon may eaſily diſtinguiſh all the Planets, except the laſt, which requires the aid of a teleſcope. For if after ſun-ſet he ſees a Planet nearer the eaſt than the weſt, he may conclude it is neither Venus nor Mercury; and he may determine whether it is Saturn, Jupiter, or Mars, by the colour, light, and magnitude: by which alſo he may diſtinguiſh between Venus and Mercury.

It is probable that all the Planets are dark opake bodies, ſimilar to the earth, and for the following reaſons.

1. Becauſe, in Mercury, Venus, and Mars, only that part of the diſk is found to ſhine which is illuminated by the ſun; and again, Venus and Mercury, when between the ſun and the earth, appear like maculæ or dark ſpots on the ſun's face: from which it is evident, that thoſe three Planets are opake bodies, illuminated by the borrowed light of the ſun. And the ſame appears of Jupiter, from his being void of light in that part to which the ſhadow of his ſatellites reaches as well as in that part turned from the ſun: and that his ſatellites are opake, and reflect the ſun's light, like the moon, is abundantly ſhewn. Moreover, ſince Saturn, with his ring and ſatellites, and alſo Herſchel, with his ſatellites, only yield a faint light, conſiderably fainter than that of the reſt of the Planets, and than that of the fixed ſtars, though theſe be vaſtly more remote; it is paſt a doubt that theſe Planets too, with their attendants, are opake bodies.

2. Since the ſun's light is not tranſmitted through Mercury or Venus, when placed againſt him, it is plain they are denſe opake bodies; which is likewiſe evident of Jupiter, from his hiding the ſatellites in his ſhadow; and therefore, by analogy, the ſame may be concluded of Saturn and Herſchel.

3. From the variable ſpots of Venus, Mars, and Jupiter, it is evident that theſe Planets have a changeable atmoſphere; which ſort of atmoſphere may, by a like argument, be inferred of the ſatellites of Jupiter; and

therefore, by ſimilitude, the ſame may be concluded of the other Planets.

4. In like manner, from the mountains obſerved in the moon and Venus, the ſame may be ſuppoſed in the other Planets.

5. Laſtly, ſince all theſe Planets are opake bodies, ſhining with the ſun's borrowed light, are furniſhed with mountains, and are encompaſſed with a changeable atmoſphere; they conſequently have waters, ſeas &c, as well as dry land, and are bodies like the moon, and therefore like the earth. And hence, it ſeems alſo probable, that the other Planets have their animal inhabitants, as well as our earth has.

Of the Orbits of the PLANETS.

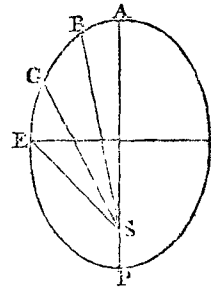
Though all the primary Planets revolve about the ſun, their orbits are not circles, but ellipſes, having the ſun in one of the foci. This circumſtance was firſt found out by Kepler, from the obſervations of Tycho Brahe: before that, all aſtronomers took the planetary orbits for eccentric circles.

The Planes of theſe orbits do all interſect in the ſun; and the line in which the plane of each orbit cuts that of the earth, is called the Line of the nodes; and the two points in which the orbits themſelves touch that plane, are the Nodes; alſo the angle in which each plane cuts that of the ecliptic, is called the Inclination of the plane or orbit.—The diſtance between the centre of the ſun, and the centre of each orbit, is called the excentricity of the Planet, or of its orbit.

The Motions of the PLANETS.

The motions of the primary Planets are very ſimple, and tolerably uniform, as being compounded only of a projectile motion, forward in a right line, which is a tangent to the orbit, and a gravitation towards the ſun at the centre. Beſides, being at ſuch vaſt diſtances from each other, the effects of their mutual gravitation towards one another are in a conſiderable degree, though not altogether, inſenſible; for the action of Jupiter upon Saturn, for ex. is found to be $\frac{1}{2\,0\,4}$ of the action of the ſun upon Saturn, by comparing the matter of Jupiter with that of the ſun, and the ſquare of the diſtance of each from Saturn. So that the elliptic orbit of Saturn will be found more juſt, if its focus be ſuppoſed not in the centre of the ſun, but in the common centre of gravity of the ſun and Jupiter, or rather in the common centre of gravity of the ſun and all the Planets below Saturn. And in like manner, the elliptic orbit of any other Planet will be found more accurate, by ſuppoſing its focus to be in the common centre of gravity of the ſun and all the Planets that are below it. But the matter is far otherwiſe, in reſpect of the ſecondary Planets: for every one of theſe, though it chiefly gravitates towards its reſpective primary one, as its centre, yet at equal diſtances from the ſun, it is alſo attracted towards him with an equally accelerated gravity, as the primary one is towards him; but at a greater diſtance with leſs, and at a nearer diſtance with greater: from which double tendency towards the ſun, and towards their own primary Planets, it happens, that the motion of the ſatellites, or ſecondary Planets, comes to be very much compounded, and affected with various inequalities.

The motions even of the primary Planets, in their elliptic orbits, are not equable, becauſe the ſun is not in their centre, but their focus. Hence they move; ſometimes faſter, and ſometimes ſlower, as they are nearer to, or farther from the ſun; but yet theſe irregularities are all certain, and follow according to an immutable law. Thus, the ellipſis PEA &c repreſenting the orbit of a Planet, and the focus S the ſun's place: the axis of the ellipſe AP, is the line of the apſes; the point A, the higher apſis or aphelion; P the lower apſis or perihelion; GS the eccentricity; and ES the Planet's mean diſtance from the ſun. Now the motion of the Planet in its perihelion P is ſwifteſt, but in its aphelion A it is ſloweſt; and at E the motion as well as the diſtance is a mean, being there ſuch as would deſcribe the whole orbit in the ſame time it is really deſcribed in. And the law by which the motion in every point is regulated, is this, that a line or radius drawn from the centre of the ſun to the centre of the Planet, and thus carried along with an angular motion, does always deſcribe an elliptic area proportional to the time; that is, the trilineal area ASB, is to the area ASG, as the time the Planet is in moving over AB, to the time it is in moving over AG. This law was firſt found out by Kepler, from obſervations; and has ſince been accounted for and demonſtrated by Sir Iſaac Newton, from the general laws of attraction and projectile motion.



As to the periods and velocities of the Planets, or the times in which they perform their courſes, they are found to have a wonderful harmony with their diſtances from the ſun, and with one another: the nearer each Planet being to the ſun, the quicker ſtill is its motion, and its period the ſhorter, according to this general and regular law; viz, that the ſquares of their periodical times are as the cubes of their mean diſtances from the ſun or focus of their orbits. The knowledge of this law we owe alſo to the ſagacity of Kepler, who found that it obtained in all the primary Planets; as aſtronomers have ſince found it alſo to hold good in the ſecondary ones. Kepler indeed deduced this law merely from obſervation, by a compariſon of the ſeveral diſtances of the Planets with their periods or times: the glory of inveſtigating it from phyſical principles is due to Sir Iſaac Newton, who has demonſtrated that, in the preſent ſtate of nature, ſuch a law was inevitable.

The phenomena of the Planets are, their Conjunctions, Oppoſitions, Elongations, Stations, Retrogradations, Phaſes, and Eclipſes; for which ſee the reſpective articles.

For a view of the comparative magnitudes of the Planets; and for a view of their ſeveral diſtances, &c; ſee the articles ORBIT and SOLAR SYSTEM, as alſo Plate xxi, fig. 1.

The following Table contains a ſynopſis of the diſtances, magnitudes, periods, &c, of the ſeveral Planets, according to the lateſt obſervations and improvements.

TABLE

TABLE *of the* PLANETARY MOTIONS, DISTANCES, &c.

Anno 1784.	MERCURY.	VENUS.	EARTH.	MARS.	JUPITER.	SATURN.	HERSCHEL, or GEORGIAN, 1782.

Proportion of Denſity; that of the Sun being ¼.	2	1¼	1	·7	·23	·02	*

A Planet's motion, or diſtance from its apogee, is called the mean anomaly of the Planet, and is meaſured by the area it deſcribes in the given time: when the Planet arrives at the middle of its orbit, or the point E, the area or time is called the true anomaly. When the Planet's motion is reckoned from the firſt point of Aries, it is called its motion in longitude; which is either mean or true; viz, mean, which is ſuch as it would have were it to move uniformly in a circle; and true, which is that with which the Planet actually deſcribes its orbit, and is meaſured by the arc of the ecliptic it deſcribes. And hence may be found the Planet's place in its orbit for any given time after it has left the aphelion: for ſuppoſe the area of the ellipſis be ſo divided by the line SG, that the whole elliptic area may have the ſame proportion to the part ASG, as the whole periodical time in which the Planet deſcribes its whole orbit, has to the given time; then will G be the Planet's place in its orbit ſought.

PLANETARIUM, an aſtronomical machine, contrived to repreſent the motions, orbits, &c, of the planets, as they really are in nature, or according to the Copernican ſyſtem. The larger ſort of them are called Orreries. See ORRERY.

A very remarkable machine of this ſort was invented by Huygens, and deſcribed in his Opuſc. Poſth. tom. 2. p. 157, edit. Amſt. 1728. And it is ſtill preſerved among the curioſities of the univerſity at Leyden.

In this Planetarium, the five primary planets perform their revolutions about the ſun, and the moon performs her revolution about the earth, in the ſame time that they are really performed in the heavens. Alſo the orbits of the moon and planets are repreſented with their true proportions, eccentricity, poſition, and declination from the ecliptic or orbit of the earth. So that by this machine the ſituation of the planets, with the conjunctions, oppoſitions, &c, may be known, not only for the preſent time, but for any other time either paſt or yet to come; as in a perpetual ephemeris.

There was exhibited in London, viz. in the year 1791, a ſtill much more complete Planetarium of this ſort; called "a Planetarium or aſtronomical machine, which exhibits the moſt remarkable phenomena, motions, and revolutions of the univerſe. Invented, and partly executed, by the celebrated M. Phil. Matthew Hahn, member of the academy of ſciences at Erfurt. But finiſhed and completed by Mr. Albert de Mylius." This is a moſt ſtupendous and elaborate machine; conſiſting of the ſolar ſyſtem in general, with all the orbits and planets in their due proportions and poſitions; as alſo the ſeveral particular planetary ſyſtems of ſuch as have ſatellites, as of the earth, Jupiter, &c; the whole kept in continual motion by a chronometer, or grand eight-day clock; by which all theſe ſyſtems are made perpetually to perform all their motions exactly as in nature, exhibiting at all times the true and real motions, poſitions, aſpects, phenomena, &c, of all the celeſtial bodies, even to the very diurnal rotation of the planets, and the unequal motions in their elliptic orbits. A deſcription was publiſhed of this moſt ſuperb machine; and it was purchaſed and ſent as one of the preſents to the emperor of China, in the embaſſy of Lord Macartney, in the year 1793.

But the Planetariums or orreries now moſt commonly uſed, do not repreſent the true times of the celeſtial motions, but only their proportions; and are not kept in continual motion by a clock, but are only turned round occaſionally with the hand, to help to give young beginners an idea only of the planetary ſyſtem; as alſo, if conſtructed with ſufficient accuracy, to reſolve problems, in a coarſe way, relating to the motions of the planets, and of the earth and moon, &c.

Dr. Deſaguliers (Exp. Philoſ. vol. 1, p. 430.) deſcribes a Planetarium of his own contrivance, which is one of the beſt of the common ſort. The machine is contrived to be rectified or ſet to any latitude; and then by turning the handle of the Planetarium, all the planets perform their revolutions round the ſun in proportion to their periodical times, and they carry indices which ſhew the longitudes of the planets, by pointing to the diviſions graduated on circles for that purpoſe.

The Planetarium repreſented in fig. 1, plate xxii. is an inſtrument contrived by Mr. Wm. Jones, of Holborn, London, mathematical inſtrument maker, who has paid conſiderable attention to ſuch machines, to bring them to a great degree of ſimplicity and perfection. It repreſents in a general manner, by various parts of its machinery, all the motions and phenomena of the planetary ſyſtem. This machine conſiſts of, the Sun in the centre, with the Planets in the order of their diſtance from him, viz. Mercury, Venus, the Earth and Moon, Mars, Jupiter with his moons, and Saturn with his ring and moons; and to it is alſo occaſionally applied an extra long arm for the Georgian Planet and his two moons. To the earth and moon is applied a frame CD, containing only four wheels and two pinions, which ſerve to preſerve the earth's axis in its due parallelism in its motion round the ſun, and to give the moon at the ſame time her due revolution about the earth. Theſe wheels are connected with the wheelwork in the round box below, and the whole is ſet in motion by the winch H. The arm M that carries round the moon, points out on the plate C her age and phaſes for any ſituation in her orbit, upon which they are engraved. In like manner the arm points out her place in the ecliptic B, in ſigns and degrees, called her geocentric place, that is, as ſeen from the earth. The moon's orbit is repreſented by the flat rim A; the two joints of it, upon which it turns, denoting her nodes; and the orbit being made to incline to any required angle. The terrella, or little earth, of this machine, is uſually made of a three inch globe papered, &c, for the purpoſe; and by means of the terminating wire that goes over it, points out the changes of the ſeaſons, and the different lengths of days and nights more conſpicuouſly. By this machine are ſeen at once all the Planets in motion about the Sun, with the ſame reſpective velocities and periods of revolution which they have in the heavens; the wheelwork being calculated to a minute of time, from the lateſt diſcoveries. See Mr. Jones's Deſcription of his new portable Orrery.

PLANETARY, ſomething that relates to the planets. Thus, we ſay Planetary worlds, Planetary inhabitants, Planetary motions, &c. Huygens and Fontenelle bring ſeveral probable arguments for the reality of Planetary worlds, animals, plants, men, &c.

PLANETARY *Syſtem*, is the ſyſtem or aſſemblage of the Planets, primary and ſecondary, moving in their reſpective

reſpective orbits, round their common centre the ſun. See *Solar* SYSTEM.

PLANETARY *Days*. With the Ancients, the week was ſhared among the ſeven planets, each planet having its day. This we learn from Dion Caſſius and Plutarch, Sympoſ. lib. 4. q. 7. Herodotus adds, that it was the Egyptians who firſt diſcovered what god, that is what planet, preſides over each day; for that among this people the planets were directors. And hence it is, that in moſt European languages the days of the week are ſtill denominated from the planets; as Sunday, Monday, &c.

PLANETARY *Dials*, are ſuch as have the Planetary hours inſcribed on them.

PLANETARY *Hours*, are the 12th parts of the artificial day and night. See *Planetary* HOUR.

PLANETARY *Squares*, are the ſquares of the ſeven numbers from 3 to 9, diſpoſed magically. Cornelius Agrippa, in his book of magic, has given the conſtruction of the ſeven Planetary ſquares. And M. Poignard, canon of Bruſſels, in his treatiſe on ſublime ſquares, gives new, general, and eaſy methods, for making the ſeven Planetary ſquares, and all others to infinity, by numbers in all ſorts of progreſſions. See MAGIC *ſquare*.

PLANETARY *Years*, the periods of time in which the ſeveral planets make their revolutions round the ſun, or earth.—As from the proper revolution of the earth, or the apparent revolution of the ſun, the ſolar year takes its original; ſo from the proper revolutions of the reſt of the planets about the earth, as many ſorts of years do ariſe; viz, the Saturnian year, which is defined by 29 Egyptian years 174 days 58 minutes, equivalent in a round number to 30 ſolar years. The Jovial year, containing 11 years 317 days 14 hours 59 minutes. The Martial year, containing 1 year 321 days 23 hours 31 minutes. For Venus and Mercury, as their years, when judged of with regard to the earth, are almoſt equal to the ſolar year; they are more uſually eſtimated from the ſun, the true centre of their motions: in which caſe the former is equal to 224 days 16 hours 49 minutes; and the latter to 87 days 23 hours 16 minutes.

PLANIMETRY, that part of geometry which conſiders lines and plane figures, without any regard to heights or depths.—Planimetry is particularly reſtricted to the menſuration of planes and other ſurfaces; as contradiſtinguiſhed from Stereometry, or the menſuration of ſolids, or capacities of length, breadth and depth.

Planimetry is performed by means of the ſquares of long meaſures, as ſquare inches, ſquare feet, ſquare yards, &c; that is, by ſquares whoſe ſide is an inch, a foot, a yard, &c. So that the area or content of any ſurface is ſaid to be found, when it is known how many ſuch ſquare inches, feet, yards, &c. it contains. See MENSURATION and SURVEYING.

PLANISPHERE, a projection of the ſphere, and its various circles, on a plane; as upon paper or the like. In this ſenſe, maps of the heavens and the earth, exhibiting the meridians and other circles of the ſphere, may be called Planiſpheres.

Planiſphere is ſometimes alſo conſidered as an aſtronomical inſtrument, uſed in obſerving the motions of the heavenly bodies; being a projection of the celeſtial ſphere upon a plane, repreſenting the ſtars, conſtellations, &c, in their proper ſituations, diſtances, &c. As the Aſtrolabe, which is a common name for all ſuch projections.

In all Planiſpheres, the eye is ſuppoſed to be in a point, viewing all the circles of the ſphere, and referring them to a plane beyond them, againſt which the ſphere is as it were flattened: and this plane is called the Plane of Projection, which is always ſome one of the circles of the ſphere itſelf, or parallel to ſome one.

Among the infinite number of Planiſpheres which may be furniſhed by the different planes of projection, and the different poſitions of the eye, there are two or three that have been preferred to the reſt. Such as that of Ptolomy, where the plane of projection is parallel to the equator: that of Gemma Friſius, where the plane of projection is the colure, or ſolſtitial meridian, and the eye the pole of the meridian, being a ſtereographical projection: or that of John de Royas, a Spaniard, whoſe plane of projection is a meridian, and the eye placed in the axis of that meridian, at an infinite diſtance; being an orthographical projection, and called the Analemma.

PLANO-*Concave* glaſs or lens, is that which is plane on one ſide, and concave on the other. And

PLANO-*Convex* glaſs or lens, is that which is plane on one ſide, and convex on the other. See LENS.

PLAT-BAND, in Architecture, is any flat ſquare moulding, whoſe height much exceeds its projecture. Such are the faces of an architrave, and the Platbands of the modillions of a cornice.

PLATFORM, in Artillery and Gunnery, a ſmall elevation, or a floor of wood, ſtone, or the like, on which cannon, &c, are placed, for more conveniently working and firing them.

PLATFORM, in Architecture, a row of beams that ſupport the timber-work of a roof, lying on the top of the walls, where the entablature ought to be raiſed. Alſo a kind of flat walk, or plane floor, on the top of a building; from whence a fair view may be taken of the adjacent grounds. So, an edifice is ſaid to be covered with a Platform, when it has no arched roof.

PLATO, one of the moſt celebrated among the ancient philoſophers, being the founder of the ſect of the Academics, was the ſon of Ariſto, and born at Athens, about 429 years before Chriſt. He was of a royal and illuſtrious family, being deſcended by his father from Codrus, and by his mother from Solon. The name given him by his parents was *Ariſtocles*; but being of a robuſt make, and remarkably broad-ſhouldered, from this circumſtance he was nick-named *Plato* by his wreſtling-maſter, which name he retained ever after.

From his infancy, Plato diſtinguiſhed himſelf by his lively and brilliant imagination. He eagerly imbibed the principles of poetry, muſic, and painting. The charms of philoſophy however prevailing, drew him from thoſe of the fine arts; and at the age of twenty he attached himſelf to Socrates only, who called him the *Swan of the Academy*. The diſciple profited ſo well of his maſter's leſſons, that at twenty-five years of age he had the reputation of a conſummate ſage. He lived with Socrates for eight years, in which time he committed to writing, according to the cuſtom of the ſtudents, the purport of a great number of his maſter's excellent lectures, which he digeſted by way of philoſo-

phical converſations; but made ſo many judicious additions and improvements of his own, that Socrates, hearing him one day recite his Lyſis, cried out, O Hercules! how many fine ſentiments does this young man aſcribe to me, that I never thought of! And Laertius aſſures us, that he compoſed ſeveral diſcourſes which Socrates had no manner of hand in. At the time when Socrates was firſt arraigned, Plato was a junior ſenator, and he aſſumed the orator's chair to plead his maſter's cauſe, but was interrupted in that deſign, and the judges paſſed ſentence of condemnation upon Socrates. Upon this occaſion Plato begged him to accept from him a ſum of money ſufficient to purchaſe his enlargement, but Socrates peremptorily refuſed the generous offer, and ſuffered himſelf to be put to death.

The philoſophers who were at Athens were ſo alarmed at the death of Socrates, that moſt of them fled, to avoid the cruelty and injuſtice of the government. Plato retired to Megara, where he was kindly entertained by Euclid the philoſopher, who had been one of the firſt ſcholars of Socrates, till the ſtorm ſhould be over. Afterwards he determined to travel in purſuit of knowledge; and from Megara he went to Italy, where he conferred with Eurytus, Philolaus, and Archytas, the moſt celebrated of the Pythagoreans, from whom he learned all his natural philoſophy, diving into the moſt profound and myſterious ſecrets of the Pythagoric doctrines. But perceiving other knowledge to be connected with them, he went to Cyrene, where he ſtudied geometry and other branches of mathematics under Theodorus, a celebrated maſter.

Hence he travelled into Egypt, to learn the theology of their prieſts, with the ſciences of arithmetic, aſtronomy, and the nicer parts of geometry. Having taken alſo a ſurvey of the country, with the courſe of the Nile and the canals, he ſettled ſome time in the province of Sais, learning of the ſages there their opinions concerning the univerſe, whether it had a beginning, whether it moved wholly or in part, &c; alſo concerning the immortality and tranſmigration of ſouls: and here it is alſo thought he had ſome communication with the books of Moſes.

Plato's curioſity was not yet ſatisfied. He travelled into Perſia, to conſult the magi as to the religion of that country. He deſigned alſo to have penetrated into India, to learn of the Brachmans their manners and cuſtoms; but was prevented by the wars in Aſia.

Afterwards, returning to Athens, he applied himſelf to the teaching of philoſophy, opening his ſchool in the Academia, a place of exerciſe in the ſuburbs of the city; from whence it was that his followers took the name of Academics.

Yet, ſettled as he was, he made ſeveral excurſions abroad: one in particular to Sicily, to view the fiery ebullitions of Mount Etna. Dionyſius the tyrant then reigned at Syracuſe; a very bad man. Plato however went to viſit him; but, inſtead of flattering him like a courtier, reproved him for the diſorders of his court, and the injuſtice of his government. The tyrant, not uſed to diſagreeable truths, grew enraged at Plato, and would have put him to death, if Dion and Ariſtomenes, formerly his ſcholars, and then favourites of that prince, had not powerfully interceded for him. Dionyſius however delivered him into the hands of an envoy of the Lacedemonians, who were then at war with the Athenians: and this envoy, touching upon the coaſt of Ægina, ſold him for a ſlave to a merchant of Cyrene; who, as ſoon as he had bought him, liberated him, and ſent him home to Athens.

Some time after, he made a ſecond voyage into Sicily, in the reign of Dionyſius the younger; who ſent Dion, his miniſter and favourite, to invite him to court, that he might learn from him the art of governing his people well. Plato accepted the invitation, and went; but the intimacy between Dion and Plato raiſing jealouſy in the tyrant, the former was diſgraced, and the latter ſent back to Athens. But Dion, being taken into favour again, perſuaded Dionyſius to recall Plato, who received him with all the marks of goodwill and friendſhip that a great prince could give. He ſent out a fine galley to meet him, and went himſelf in a magnificent chariot, attended by all his court, to receive him. But this prince's uneven temper hurried him into new ſuſpicions. It ſeems indeed that theſe apprehenſions were not altogether groundleſs: for Ælian ſays, and Cicero was of the ſame opinion, that Plato taught Dion how to diſpatch the tyrant, and to deliver the people from oppreſſion. However this may be, Plato was offended and complained; and Dionyſius, incenſed at theſe complaints, reſolved to put him to death: but Archytas, who had great intereſt with the tyrant, being informed of it by Dion, interceded for the philoſopher, and obtained leave for him to retire.

The Athenians received him joyfully at his return, and offered him the adminiſtration of the government; but he declined that honour, chooſing rather to live quietly in the Academy, in the peaceable contemplation and ſtudy of philoſophy; being indeed ſo deſirous of a private retirement that he never married. His fame drew diſciples from all parts, when he would admit them, as well as invitations to come to reſide in many of the other Grecian ſtates; but the three that moſt diſtinguiſhed themſelves, were Spuſippus his nephew, who continued the Academy after him, Xenocrates the Caledonian, and the celebrated Ariſtotle. It is ſaid alſo that Theophraſtus and Demoſthenes were two of his diſciples. He had it ſeems ſo great a reſpect for the ſcience of geometry and the mathematics, that he had the following inſcription painted in large letters over the door of his academy; LET NO ONE ENTER HERE, UNLESS HE HAS A TASTE FOR GEOMETRY AND THE MATHEMATICS!

But as his great reputation gained him on the one hand many diſciples and admirers, ſo on the other it raiſed him ſome emulators, eſpecially among his fellow-diſciples, the followers of Socrates. Xenophon and he were particularly diſaffected to each other. Plato was of ſo quiet and even a temper of mind, even in his youth, that he never was known to expreſs a pleaſure with any greater emotion than that of a ſmile; and he had ſuch a perfect command of his paſſions, that nothing could provoke his anger or reſentment; from hence, and the ſubject and ſtyle of his writings, he acquired the appellation of the *Divine Plato*. But although he was naturally of a reſerved and very penſive diſpoſition; yet, according to Ariſtotle, he was affable, courteous, and perfectly good-natured; and ſometimes would condeſcend

ſcend to crack little innocent jokes on his intimate acquaintances. Of his affability there needs no greater proof than his civil manner of converſing with the philoſophers of his own times, when pride and envy were at their height. His behaviour to Diogenes is always mentioned in his hiſtory. This Cynic was greatly offended, it ſeems, at the politeneſs and fine taſte of Plato, and uſed to catch all oppórtunities of ſnarling at him. Dining one day at his table with other company, when trampling upon the tapeſtry with his dirty feet, he uttered this brutiſh ſarcaſm, "I trample upon the pride of Plato:" to which the latter wiſely and calmly replied, "with a greater pride."

This extraordinary man, being arrived at 81 years of age, died a very eaſy and peaceable death, in the midſt of an entertainment, according to ſome; but, according to Cicero, as he was writing. Both the life and death of this philoſopher were calm and undiſturbed; and indeed he was finely compoſed for happineſs. Beſide the advantages of a noble birth, he had a large and comprehenſive underſtanding, a vaſt fund of wit and good taſte, great evenneſs and ſweetneſs of temper, all cultivated and refined by education and travel; ſo that it is no wonder he was honoured by his countrymen, eſteemed by ſtrangers, and adored by his ſcholars. Tully perfectly adored him: he tells us that he was juſtly called by Panætius, the divine, the moſt wiſe, the moſt ſacred, the Homer of philoſophers; thinks, that if Jupiter had ſpoken Greek, he would have done it in Plato's ſtyle, &c. But, panegyric aſide, Plato was certainly a very wonderful man, of a large and comprehenſive mind, an imagination infinitely fertile, and of a moſt flowing and copious eloquence. However, the ſtrength and heat of fancy prevailing over judgment in his compoſition, he was too apt to ſoar beyond the limits of earthly things, to range in the imaginary regions of general and abſtracted ideas; on which account, though there is always a greatneſs and ſublimity in his manner, he did not philoſophize ſo much according to truth and nature as Ariſtotle, though Cicero did not ſcruple to give him the preference.

The writings of Plato are all in the way of dialogue, where he ſeems to deliver nothing from himſelf, but every thing as the ſentiments and opinions of others, of Socrates chiefly, of Timæus, &c. His ſtyle, as Ariſtotle obſerved, is between proſe and verſe: on which account ſome have not ſcrupled to rank him among the poets: and indeed, beſide the elevation and grandeur of his ſtyle, his matter is frequently the offſpring of imagination, inſtead of doctrines or truths deduced from nature. The firſt edition of Plato's works in Greek, was printed by Aldus at Venice in 1513: but a Latin verſion of them by Marſilius Ficinus had been printed there in 1491. They were reprinted together at Lyons in 1588, and at Francfort in 1602. The famous printer Henry Stephens, in 1578, gave a beautiful and correct edition of Plato's works at Paris, with a new Latin verſion by Serranus, in three volumes folio.

PLATONIC, ſomething that relates to Plato, his ſchool, philoſophy, opinions, or the like.

PLATONIC *Bodies*, ſo called from Plato who treated of them, are what are otherwiſe called the regular bodies. They are five in number; the tetraedron, the hexaedron, the octaedron, the dodecaedron, and the icoſaedron. See each of theſe articles, as alſo REGULAR BODIES.

PLATONIC *Year*, or the *Great Year*, is a period of time determined by the revolution of the equinoxes, or the time in which the ſtars and conſtellations return to their former places, in reſpect of the equinoxes.

The Platonic year, according to Tycho Brahe, is 25816 ſolar years, according to Riccioli 25920, and according to Caſſini 24800 years.

This period being once accompliſhed, it was an opinion among the ancients, that the world was to begin anew, and the ſame ſeries of things to return over again.

PLATONISM, the doctrine and ſentiments of Plato and his followers, with regard to philoſophy, &c. His diſciples were called Academics, from Academia, the name of a villa in the ſuburbs of Athens where he opened his ſchool. Among theſe were Xenocrates, Ariſtotle, Lycurgus, Demoſthenes, and Iſocrates. In phyſics, he chiefly followed Heraclitus; in ethics and politics, Socrates; and in metaphyſics, Pythagoras.

After his death, two of the principal of his diſciples, Xenocrates and Ariſtotle, continuing his office, and teaching, the one in the Academy, the other in the Lycæum, formed two ſects, under different names, though in other reſpects the ſame; the one retaining the denomination of ACADEMICS, the other aſſuming that of PERIPATETICS. See theſe two articles.

Afterwards, about the time of the firſt ages of Chriſtianity, the followers of Plato quitted the title of *Academiſts*, and took that of *Platoniſts*. It is ſuppoſed to have been at Alexandria, in Egypt, that they firſt aſſumed this new title, after having reſtored the ancient academy, and re-eſtabliſhed Plato's ſentiments; which had many of them been gradually dropped and laid aſide. Porphyry, Plotin, Iamblichus, Proclus, and Plutarch, are thoſe who acquired the chief reputation among the Greek Platoniſts; Apuleius and Chalcidius, among the Latins; and Philo Judæus, among the Hebrews. The modern Platoniſts own Plotin the founder, or at leaſt the reformer, of their ſect.

The Platonic philoſophy appears very conſiſtent with the Moſaic; and many of the primitive fathers follow the opinions of that philoſopher, as being favourable to Chriſtianity. Juſtin is of opinion that there are many things in the works of Plato which this philoſopher could not learn from mere natural reaſon; but thinks he muſt have learnt them from the books of Moſes, which he might have read when in Egypt. Hence Numenius the Pythagorean expreſsly calls Plato the *Attic Moſes*, and upbraids him with plagiariſm; becauſe he ſtole his doctrine concerning God and the world from the books of Moſes. Theodoret ſays expreſsly, that he has nothing good and commendable concerning the Deity and his worſhip, but what he took from the Hebrew theology; and Clemens Alexandrinus calls him the *Hebrew Philoſopher*. Gale is very particular in his proof of the point, that Plato borrowed his philoſophy from the Scriptures, either immediately, or by means of tradition; and, beſide the authority of the ancient writers, he brings ſome arguments from the thing itſelf. For example, Plato's confeſſion, that the Greeks borrowed their knowledge of the one infinite God, from an ancient people, better and

nearer to God than they; by which people, our author makes no doubt, he meant the Jews, from his account of the ſtate of innocence; as, that man was born of the earth, that he was naked, that he enjoyed a truly happy ſtate, that he converſed with brutes, &c. In fact, from an examination of all the parts of Plato's philoſophy, phyſical, metaphyſical, and ethical, this author finds, in every one, evident marks of its ſacred original.

As to the manner of the creation, Plato teaches, that the world was made according to a certain exemplar, or idea, in the divine architect's mind. And all things in the univerſe, in like manner, he ſhews, do depend on the efficacy of internal ideas. This ideal world is thus explained by Didymus: 'Plato ſuppoſes certain patterns, or exemplars, of all ſenſible things, which he calls ideas; and as there may be various impreſſions taken off from the ſame ſeal, ſo he ſays are there a vaſt number of natures exiſting from each idea.' This idea he ſuppoſes to be an eternal eſſence, and to occaſion the ſeveral things in nature to be ſuch as itſelf is. And that moſt beautiful and perfect idea, which comprehends all the reſt, he maintains to be the world.

Farther, Plato teaches that the univerſe is an intelligent animal, conſiſting of a body and a ſoul, which he calls *the generated God*, by way of diſtinction from what he calls the *immutable eſſence*, who was the cauſe of the generated God, or the univerſe.

According to Plato, there were two ſorts of inferior and derivative gods; the mundane gods, all of which had a temporary generation with the world; and the ſupramundane eternal gods, which were all of them, one excepted, produced from that one, and dependent on it as their cauſe. Dr. Cudworth ſays, that Plato aſſerted a plurality of gods, meaning animated or intellectual beings, or dæmons, ſuperior to men, to whom honour and worſhip are due; and applying the appellation to the ſun, moon, and ſtars, and alſo to the earth. He aſſerts however, at the ſame time, that there was one ſupreme God, the ſelf originated being, the maker of the heaven and earth, and of all thoſe other gods. He alſo maintains, that the Pſyche, or univerſal mundane ſoul, which is a ſelf-moving principle, and the immediate cauſe of all the motion in the world, was neither eternal nor ſelf-exiſtent, but made or produced by God in time; and above this ſelf-moving Pſyche, but ſubordinate to the Supreme Being, and derived by emanation from him, he ſuppoſes an immoveable Nous or intellect, which was properly the Demiurgus, or framer of the world.

The firſt matter of which this body of the univerſe was formed, he obſerves, was a rude indigeſted heap, or chaos: Now, adds he, the creation was a mixed production; and the world is the reſult of a combination of neceſſity and underſtanding, that is, of matter, which he calls neceſſity, and the divine wiſdom: yet ſo that mind rules over neceſſity; and to this neceſſity he aſcribes the introduction and prevalence both of moral and natural evil.

The principles, or elements, which Plato lays down, are fire, air, water, and earth. He ſuppoſes two heavens, the Empyrean, which he takes to be of a fiery nature, and to be inhabited by angels, &c; and the Starry heaven, which he teaches is not adamantine, or ſolid, but liquid and ſpirable.

With regard to the human ſoul, Plato maintained its tranſmigration, and conſequently its future immortality and pre-exiſtence. He aſſerted, that human ſouls are here in a lapſed ſtate, and that ſouls ſinning ſhould fall down into theſe earthly bodies. Euſebius expreſsly ſays, that Plato held the ſoul to be ungenerated, and to be derived by emanation from the firſt cauſe.

His phyſics, or doctrine *de corpore*, is chiefly laid down in his Timæus, where he argues on the properties of body in a geometrical manner; which Ariſtotle takes occaſion to reprehend in him. His doctrine *de mente* is delivered in his 10th Book of Laws, and his Parmenides.

St. Auguſtine commends the Platonic philoſophy; and even ſays, that the Platoniſts were not far from Chriſtianity. It is alſo certain that moſt of the celebrated fathers were Platoniſts, and borrowed many of their explanations of ſcripture from the Platonic ſyſtem. To account for this fact, it may be obſerved, that towards the end of the ſecond century, a new ſect of philoſophers, called the modern, or later, Platonics, aroſe of a ſudden, ſpread with amazing rapidity through the greateſt part of the Roman empire, ſwallowed up almoſt all the other ſects, and proved very detrimental to Chriſtianity.

The ſchool of Alexandria in Egypt, inſtituted by Ptolomy Philadelphus, renewed and reformed the Platonic philoſophy. The votaries of this ſyſtem diſtinguiſhed themſelves by the title of Platonics, becauſe they thought that the ſentiments of Plato concerning the Deity and inviſible things, were much more rational and ſublime than thoſe of the other philoſophers. This new ſpecies of Platoniſm was embraced by ſuch of the Alexandrian Chriſtians as were deſirous to retain, with the profeſſion of the goſpel, the title, the dignity, and the habit of philoſophers. Ammonius Saccas was its principal founder, who was ſucceeded by his diſciple Plotinus, as this latter was by Porphyry, the chief of thoſe formed in his ſchool. From the time of Ammonius until the ſixth century, this was almoſt the only ſyſtem of philoſophy publicly taught at Alexandria. It was brought into Greece by Plutarch, who renewed at Athens the celebrated Academy, from whence iſſued many illuſtrious philoſophers. The general principle on which this ſect was founded, was, that truth was to be purſued with the utmoſt liberty, and to be collected from all the different ſyſtems in which it lay diſperſed. But none that were deſirous of being ranked among theſe new Platoniſts, called in queſtion the main doctrines; thoſe, for example, which regarded the exiſtence of one God, the fountain of all things; the eternity of the world; the dependance of matter upon the Supreme Being; the nature of ſouls; the plurality of gods, &c.

In the fourth century, under the reign of Valentinian, a dreadful ſtorm of perſecution aroſe againſt the Platoniſts; many of whom, being accuſed of magical practices, and other heinous crimes, were capitally convicted.

In the fifth century Proclus gave new life to the doctrine of Plato, and reſtored it to its former credit in Greece; with whom concurred many of the Chriſtian doctors, who adopted the Platonic ſyſtem. The

Platonic

Platonic philoſophers were generally oppoſers of Chriſtianity; but in the fifth century, Chalcidius gave the Pagan ſyſtem an evangelical aſpect; and thoſe who, before it became the religion of the ſtate, ranged themſelves under the ſtandard of Plato, now repaired to that of Chriſt, without any great change of their ſyſtem.

Under the emperor Juſtinian, who iſſued a particular edict, prohibiting the teaching of philoſophy at Athens, which edict ſeems to have been levelled at modern Platoniſm, all the celebrated philoſophers of this ſect took refuge among the Perſians, who were at that time the enemies of Rome; and though they returned from their voluntary exile, when the peace was concluded between the Perſians and Romans, in 533, they could never recover their former credit, nor obtain the direction of the public ſchools.

Platoniſm however prevailed among the Greeks, and was by them, and particularly by Gemiſtius Pletho, introduced into Italy, and eſtabliſhed, under the auſpices of Coſmo de Medicis, about the year 1439, who ordered Marſilius Ficinus to tranſlate into Latin the works of the moſt renowned Platoniſts.

PLATONISTS, the followers of Plato; otherwiſe called Academics, from Academia, the name of the place that philoſopher choſe for his reſidence at Athens.

PLEIADES, an aſſemblage of ſeven ſtars in the neck of the conſtellation Taurus, the bull; although there are now only ſix of them viſible to the naked eye. The largeſt of theſe is of the third magnitude, and called Lucido Pleiadum.

The Greeks fabled, that the name Pleiades was given to theſe ſtars from ſeven daughters of Atlas and Pleione one of the daughters of Oceanus, who having been the nurſes of Bacchus, were for their ſervices taken up to heaven and placed there as ſtars, where they ſtill ſhine. The meaning of which fable may be, that Atlas firſt obſerved theſe ſtars, and called them by the names of the daughters of his wife Pleione.

PLENILUNIUM, the full-moon.

PLENUM, in Phyſics, ſignifies that ſtate of things, in which every part of ſpace, or extenſion, is ſuppoſed to be full of matter: in oppoſition to a Vacuum, which is a ſpace devoid of all matter.

The Carteſians held the doctrine of an abſolute Plenum; namely on this principle, that the eſſence of matter conſiſts in extenſion; and conſequently, there being every where extenſion or ſpace, there is every where matter: which is little better than begging the queſtion.

PLINTH, in Architecture, a flat ſquare member in form of a brick or tile; uſed as the foot or foundation of columns and pillars, &c.

PLOT, in Surveying, the plan or draught of any parcel of ground; as a field, farm, or manor, &c.

PLOTTING, in Surveying, the deſcribing or laying down on paper, the ſeveral angles and lines, &c, of a tract of land, that has been ſurveyed and meaſured.

Plotting is uſually performed by two inſtruments, the protractor and Plotting-ſcale; the former ſerving to lay off all the angles that have been meaſured and ſet down, and the latter all the meaſured lines. See theſe two inſtruments under their reſpective names.

PLOTTING *Scale*, a mathematical inſtrument chiefly uſed for the plotting of grounds in ſurveying, or ſetting off the lengths of the lines. It is either 6, 9, or 12 inches in length, and about an inch and half broad; being made either of box-wood, braſs, ivory, or ſilver; thoſe of ivory are the neateſt.

This inſtrument contains various ſcales or divided lines, on both ſides of it. On the one ſide are a number of plane ſcales, or ſcales of equal diviſions, each of a different number to the inch; as alſo ſcales of chords, for laying down angles; and ſometimes even the degrees of a circle marked on one edge, anſwering to a centre marked on the oppoſite edge, by which means it ſerves alſo as a protractor. On the other ſide are ſeveral diagonal ſcales, of different ſizes, or different diviſions to the inch; ſerving to take off lines expreſſed by numbers to three dimenſions, as units, tens, and hundreds; as alſo a ſcale of diviſions which are the 100th parts of a foot. But the moſt uſeful of all the lines that can be laid upon this inſtrument, though not always done, is a line or plane ſcale upon the two oppoſite edges, made thin for that purpoſe. This is a very uſeful line in ſurveying; for by laying the inſtrument down upon the paper, with its divided edge along a line upon which are to be laid off ſeveral diſtances, for the places of off-ſets, &c; theſe diſtances are all transferred at once from the inſtrument to the line on the paper, by making ſmall marks or points againſt the reſpective diviſions on the edge of the ſcale. See fig. 2 & 3, plates xxi and xxii.

PLOTTING-*Table*, in Surveying, is uſed for a plane table, as improved by Mr. Beighton, who has obviated a good many inconveniencies attending the uſe of the common plane table. See Philoſ. Tranſ. numb. 461, ſect. 1.

PLOUGH, or PLOW, in Navigation, an ancient mathematical inſtrument, made of box or pear-tree, and uſed to take the height of the ſun or ſtars, in order to find the latitude. This inſtrument admits of the degrees to be very large, and has been much eſteemed by many artiſts; though now quite out of uſe.

PLUMB-LINE, a term among artificers for a line perpendicular to the horizon.

PLUMMET, PLUMB-RULE, or PLUMB-LINE, an inſtrument uſed by maſons, carpenters, &c, to draw perpendiculars; in order to judge whether walls, &c, be upright, or planes horizontal, and the like.

PLUNGER, in Mechanics, a ſolid braſs cylinder, uſed as a forcer in forcing pumps.

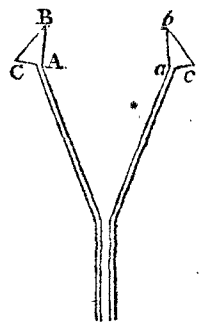
PLUS, in Algebra, the affirmative or poſitive ſign, +, ſignifying more or addition, or that the quantity following it is either to be conſidered as a poſitive or affirmative quantity, or that it is to be added to the other quantities; ſo 4 + 6 = 10, is read thus, 4 plus 6 is equal to 10. See AFFIRMATIVE *Sign*.

The more early writers of Algebra, as Lucas de Burgo, Cardan, Tartaglia, &c, wrote the word moſtly at full length. Afterwards the word was contracted or abbreviated, uſing one or two of its firſt letters; which initial was, by the Germans I think, corrupted to the preſent character +; which I find firſt uſed by Stifelius, printed in his Arithmetic.

PLUVIAMETER, a machine for meaſuring the quantity of rain that falls. There is deſcribed in the Philoſ. Tranſ. (numb. 473, or Abridg. x. 456), by Robert Pickering, under the name of an Ombrameter,

an inſtrument of this kind. It conſiſts of a tin funnel *d*, whoſe ſurface is an inch ſquare (fig. 6, plate xx); a flat board *aa*; and a glaſs tube *bb*, ſet into the middle of it in a groove; and an index with diviſions *cc*; the board and tube being of any length at pleaſure. The bore of the tube is about half an inch, which Mr. Pickering ſays is the beſt ſize. The machine is fixed in ſome free and open place, as the top of the houſe, &c.

The Rain-gage employed at the houſe of the Royal Society is deſcribed by Mr. Cavendiſh, in the Philoſ. Tranſ. for 1776, p. 384. The veſſel which receives the rain is a conical funnel, ſtrengthened at the top by a braſs ring, 12 inches in diameter. The ſides of the funnel and inner lip of the braſs ring are inclined to the horizon, in an angle of above 65°; and the outer lip in an angle of above 50°; which are ſuch degrees of ſteepneſs, that there ſeems no probability either that any rain which falls within the funnel, or on the inner lip of the ring, ſhall daſh out, or that any which falls on the outer lip ſhall daſh into the funnel. The annexed figure is a vertical ſection of the funnel, ABC and *abc* being the braſs ring, BA and *ba* the inner lip, and BC and *bc* the outer.



Note, that in fixing Pluviameters care ſhould be taken that the rain may have free acceſs to them, without being impeded or overſhaded by buildings, &c; and therefore the tops of houſes are moſtly to be preferred. Alſo when the quantities of rain collected in them, at different places, are compared together, the inſtruments ought to be fixed at the ſame height above the ground at both places; becauſe at different heights the quantities are always different, even in the ſame place. And hence alſo, any regiſter or account of rain in the Pluviameter, ought to be accompanied with a note of the height above the ground the inſtrument is placed at. See *Quantity of* RAIN.

PNEUMATICS, that branch of natural philoſophy which treats of the weight, preſſure, and elaſticity of the air, or elaſtic fluids, with the effects ariſing from them. Wolfius, inſtead of Pneumatics, uſes the term Aerometry.

This is a ſiſter ſcience to Hydroſtatics; the one conſidering the air in the ſame manner as the other does water. And ſome conſider Pneumatics as a branch of mechanics; becauſe it conſiders the air in motion, with the conſequent effects.

For the nature and properties of air, ſee the article AIR, where they are pretty largely treated of. To which may be added the following, which reſpects more particularly the ſcience of Pneumatics, as contained in a few propoſitions, and their corollaries.

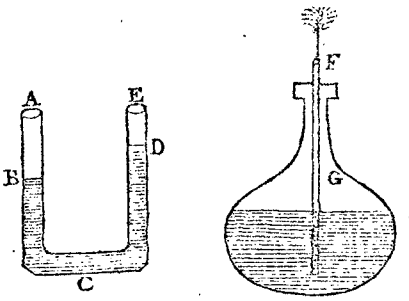
PROP. I. *The Air is a heavy fluid body, which ſurrounds and gravitates upon all parts of the ſurface of the earth.*

Theſe properties of air are proved by experience. That it is a fluid, is evident from its eaſily yielding to any the leaſt force impreſſed upon it, with little or no ſenſible reſiſtance.

But when it is moved briſkly, by any means, as by a fan, or a pair of bellows; or when any body is moved ſwiftly through it; in theſe caſes we become ſenſible of it as a body, by the reſiſtance it makes in ſuch motions, and alſo by its impelling or blowing away any light ſubſtances. So that, being capable of reſiſting, or moving other bodies by its impulſe, it muſt itſelf be a body, and be heavy, like all other bodies, in proportion to the matter it contains; and therefore it will preſs upon all bodies that are placed under it.

And being a fluid, it will ſpread itſelf all over upon the earth; alſo like other fluids it will gravitate upon, and preſs every where upon the earth's ſurface.

The gravity and preſſure of the air is alſo evident from many experiments. Thus, for inſtance, if water, or quick-ſilver, be poured into the tube ACE, and the air be ſuffered to preſs upon it, in both ends of the tube; the fluid will reſt at the ſame height in both the legs: but if the air be drawn out of one end as E, by any means; then the air preſſing on the other end A, will preſs down the fluid in this leg at B, and raiſe it up in the other to D, as much higher than at B, as the preſſure of the air is equal to. By which it appears, not only that the air does really preſs, but alſo what the quantity of that preſſure is equal to. And this is the principle of the Barometer.



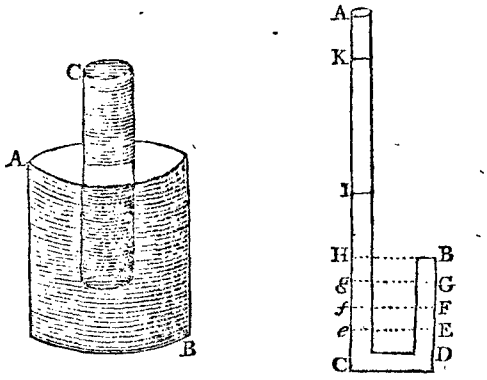
PROP. II. *The air is alſo an elaſtic fluid, being condenſible and expanſible. And the law it obſerves in this reſpect is this, namely, that its denſity is always proportional to the force by which it is compreſſed.*

This property of the air is proved by many experiments. Thus, if the handle of a ſyringe be puſhed inwards, it will condenſe the incloſed air into a leſs ſpace; by which it is ſhewn to be condenſible. But the included air, thus condenſed, will be felt to act ſtrongly againſt the hand, and to reſiſt the force compreſſing it more and more; and on withdrawing the hand, the handle is puſhed back again to where it was at firſt. Which ſhews that the air is elaſtic.

Again, fill a ſtrong bottle half full with water, and then inſert a pipe into it, putting its lower end down near to the bottom, and cementing it very cloſe round the mouth of the bottle. Then if air be ſtrongly injected through the pipe, as by blowing with the mouth or otherwiſe, it will paſs through the water from the lower end, and aſcend up into the part before occupied by

by the air at G, and the whole mass of air become there condensed because the water is not easily compressed into a less space. But on removing the force which injected the air at F, the water will begin to rise from thence in a jet, being pushed up the pipe by the increased elasticity of the air G, by which it presses on the surface of the water, and forces it through the pipe, till as much be expelled as there was air forced in; when the air at G will be reduced to the same density as at first, and, the balance being restored, the jet will cease.

Likewise, if into a jar of water AB, be inverted an empty glass tumbler C, or such like; the water will

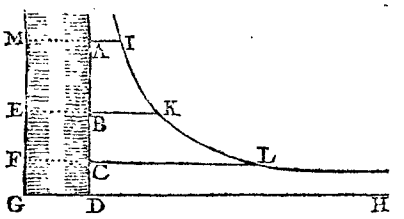


enter it, and partly fill it, but not near so high as the water in the jar, compressing and condensing the air into a less space in the upper part C, and causing the glass to make a sensible resistance to the hand in pushing it down. But on removing the hand, the elasticity of the internal condensed air throws the glass up again.—All these shewing that the air is condensible and elastic.

Again, to shew the rate or proportion of the elasticity to the condensation; take a long slender glass tube, open at the top A, bent near the bottom or close end B, and equally wide throughout, or at least in the part BD (2d fig. above). Pour in a little quicksilver at A, just to cover the bottom to the bend at CD, and to stop the communication between the external air and the air in BD. Then pour in more quicksilver, and observe to mark the corresponding heights at which it stands in the two legs: so, when it rises to H in the open leg AC, let it rise to E in the close one, reducing its included air from the natural bulk BD to the contracted space BE, by the pressure of the column H*e*; and when the quicksilver stands at I and K, in the open leg, let it rise to F and G in the other, reducing the air to the respective spaces BF, BG, by the weights of the columns I*f*, K*g*. Then it is always found, that the condensations and elasticities are as the compressing weights, or columns of the quicksilver and the atmosphere together. So, if the natural bulk of the air BD be compressed into the spaces BE, BF, BG, or reduced by the spaces DE, DF, DG, which are $\frac{1}{4}$, $\frac{1}{2}$, $\frac{3}{4}$ of BD, or as the numbers 1, 2, 3; then the atmosphere, together with the corresponding column H*e*, I*f*, K*g*, will also be found to be in the same proportion, or as the numbers 1, 2, 3: and then the weights of the quicksilver are thus, viz, H*e* = $\frac{1}{3}$A, I*f* = A, and K*g* = 3A; where A denotes the weight of the atmosphere. Which shews that the condensations are directly as the compressing forces. And the elasticities are also in the same proportion, since the pressures in AC are sustained by the elasticities in BD.

From the foregoing principles may be deduced many useful remarks, as in the following corollaries, viz:

Corol. 1. The space that any quantity of air is confined in, is reciprocally as the force that compresses it. So, the forces which confine a quantity of air in the



cylindrical spaces AG, BG, CG, are reciprocally as the same, or reciprocally as the heights AD, BD, CD. And therefore, if to the two perpendicular lines AD, DH, as asymptotes, the hyperbola IKL be described, and the ordinates AI, BK, CL be drawn; then the forces which confine the air in the spaces AG, BG, CG, will be as the corresponding ordinates AI, BK, CL, since these are reciprocally as the abscisses AD, BD, CD, by the nature of the hyperbola.

Corol. 2. All the air near the earth is in a state of compression, by the weight of the incumbent atmosphere.

Corol. 3. The air is denser near the earth, than in high places; or denser at the foot of a mountain, than at the top of it. And the higher above the earth, the rarer it is.

Corol. 4. The spring or elasticity of the air, is equal to the weight of the atmosphere above it; and they will produce the same effects; since they are always sustained and balanced by each other.

Corol. 5. If the density of the air be increased, preserving the same heat or temperature; its spring or elasticity will likewise be increased, and in the same proportion.

Corol. 6. By the gravity and pressure of the atmosphere upon the surfaces of fluids, the fluids are made to rise in any pipes or vessels, when the spring or pressure within is diminished or taken off.

Prop. III. *Heat increases the elasticity of the air, and cold diminishes it. Or heat expands, and cold contracts and condenses the air.*

This property is also proved by experience.

Thus, tie a bladder very close, with some air in it; and lay it before the fire; then as it warms, it will more and more distend the bladder, and at last burst it, if the heat be continued and increased high enough. But if the bladder be removed from the fire; it will contract again to its former state by cooling.——It was upon this principle that the first air-balloons were made by Montgolfier: for by heating the air within them, by a fire underneath, the hot air distends them to a size which occupies a space in the atmosphere whose weight of common air exceeds that of the balloon.

Also, if a cup or glass, with a little air in it, be inverted into a vessel of water; and the whole be heated

over the fire, or otherwiſe: the air in the top will expand till it fill the glaſs, and expel the water out of it; and part of the air itſelf will follow, by continuing or increaſing the heat.

Many other experiments to the ſame effect might be adduced, all proving the properties mentioned in the propoſition.

Schol. Hence, when the force of the elaſticity of the air is conſidered, regard muſt be had to its heat or temperature; the ſame quantity of air being more or leſs elaſtic, as its heat is more or leſs. And it has been found by experiment that its elaſticity is increaſed at the following rate, viz, by the 435th part, by each degree of heat expreſſed by Fahrenheit's thermometer, of which there are 180 between the freezing and boiling heat of water. It has alſo been found (Philoſ. Tranſ. 1777, pa. 560 &c), that water expands the 6666th part, with each degree of heat; and mercury the 9600th part by each degree. Moreover, the relative or ſpecific gravities of theſe three ſubſtances, are as follow: viz,

Air	1·232	when the barom. is at 30, and the thermom. at 55.
Water	1000	
Mercury	13600	

Alſo theſe numbers are the weights of a cubic foot of each, in the ſame circumſtances of the barometer and thermometer.

PROP. IV. *The weight or preſſure of the atmoſphere, upon any baſe at the ſurface of the earth, is equal to the weight of a column of quickſilver of the ſame baſe, and its height between* 28 *and* 31 *inches.*

This is proved by the barometer, an inſtrument which meaſures the preſſure of the air; the deſcription of which ſee under its proper article. For at ſome ſeaſons, and in ſome places, the air ſuſtains and balances a column of mercury of about 28 inches; but at others, it balances a column of 29, or 30, or near 31 inches high; ſeldom in the extremes 28 or 31, but commonly about the means 29 or 30, and indeed moſtly near 30. A variation which depends partly on the different degrees of heat in the air near the ſurface of the earth, and partly on the commotions and changes in the atmoſphere, from winds and other cauſes, by which it is accumulated in ſome places, and depreſſed in others, being thereby rendered denſer and heavier, or rarer and lighter; which changes in its ſtate are almoſt continually happening in any one place. But the medium ſtate is from 29½ to 30 inches.

Corol. 1. Hence the preſſure of the atmoſphere upon every ſquare inch at the earth's ſurface, at a medium, is very near 15 pounds avoirdupois. For, a cubic foot of mercury weighing nearly 13600 ounces, a cubic inch of it will weigh the 1728th part of it, or almoſt 8 ounces, or half a pound, which is the weight of the atmoſphere for every inch of the barometer upon a baſe of a ſquare inch; and therefore 29¾ inches, the medium height of the barometer, weighs almoſt 15 pounds, or rather 14¾lb very nearly.

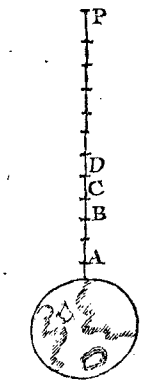
Corol. 2. Hence alſo the weight or preſſure of the atmoſphere, is equal to that of a column of water from 32 to 35 feet high, or on a medium 33 or 34 feet high. For water and quickſilver are in weight nearly as 1 to 13·6; ſo that the atmoſphere will balance a column of water 13·6 times higher than one of quickſilver; conſequently 13·6 × 30 inches = 408 inches or 34 feet, is near the medium height of water, or it is more nearly 33¾ feet. And hence it appears that a common ſucking pump will not raiſe water higher than about 34 feet. And that a ſyphon will not run if the perpendicular height of the top of it be more than 33 or 34 feet.

Corol. 3. If the air were of the ſame uniform denſity, at every height, up to the top of the atmoſphere, as at the ſurface of the earth; its height would be about 5¼ miles at a medium. For the weights of the ſame volume of air and water, are nearly as 1·232 to 1000; therefore as 1·232 : 1000 :: 34 feet : 27600 feet, or 5¼ miles very nearly. And ſo high the atmoſphere would be, if it were all of uniform denſity, like water. But, inſtead of that, from its expanſive and elaſtic quality, it becomes continually more and more rare the farther above the earth, in a certain proportion which will be treated of below.

Corol. 4. From this prop. and the laſt, it follows that the height is always the ſame, of an uniform atmoſphere above any place, which ſhall be all of the uniform denſity with the air there, and of equal weight or preſſure with the real height of the atmoſphere above that place, whether it be at the ſame place at different times, or at any different places or heights above the earth; and that height is always about 27600 feet, or 5¼ miles, as found above in the 3d corollary. For, as the denſity varies in exact proportion to the weight of the column, it therefore requires a column of the ſame height in all caſes, to make the reſpective weights or preſſures. Thus, if W and w be the weights of atmoſphere above any places, D and d their denſities, and H and h the heights of the uniform columns, of the ſame denſities and weights: Then $H \times D = W$, and $h \times d = w$; therefore $\frac{W}{D}$ or H is equal to $\frac{w}{d}$, or h; the temperature being the ſame.

PROP. V. *The denſity of the atmoſphere, at different heights above the earth, decreaſes in ſuch ſort, that when the heights increaſe in arithmetical progreſſion, the denſities decreaſe in geometrical progreſſion.*

Let the perpendicular line AP, erected on the earth, be conceived to be divided into a great number of very ſmall parts A, B, C, D, &c, forming ſo many thin ſtrata of air in the atmoſphere, all of different denſity, gradually decreaſing from the greateſt at A: then the denſity of the ſeveral ſtrata A, B, C, D, &c, will be in geometrical progreſſion decreaſing.



For, as the ſtrata A, B, C, &c, are all of equal thickneſs, the quantity of matter in each of them, is as the denſity there; but the denſity in any one, being as the compreſſing force, is as the weight or quantity of matter from that place upward to the top of the atmoſphere; therefore the quantity of matter in each ſtratum, is alſo as the whole quantity from that place upwards. Now if from the whole weight at any

place

place as B, the weight or quantity in the ſtratum B be ſubtracted, the remainder will be the weight at the next higher ſtratum C; that is, from each weight ſubtracting a part which is proportional to itſelf, leaves the next weight; or, which is the ſame thing, from each denſity ſubtracting a part which is always proportional to itſelf, leaves the next denſity. But when any quantities are continually diminiſhed by parts which are proportional to themſelves, the remainders then form a ſeries of continued proportionals; and conſequently theſe denſities are in geometrical progreſſion.

Thus, if the firſt denſity be D, and from each there be taken its nth part; then there remains its $\frac{n-1}{n}$ part, or the $\frac{m}{n}$ part, putting m for $n-1$; and therefore the ſeries of denſities will be D, $\frac{m}{n}$D, $\frac{m^2}{n^2}$D, $\frac{m^3}{n^3}$D, &c, $\frac{m}{n}$ being the common ratio of the ſeries.

Schol. Becauſe the terms of an arithmetical ſeries, are proportional to the logarithms of the terms of a geometrical ſeries; therefore different altitudes above the earth's ſurface, are as the logarithms of the denſities, or weights of air, at thoſe altitudes. So that,

if D denote the denſity at the altitude A,
and d the denſity at the altitude a;
then A being as the logarithm of D,
and a as the logarithm of d,
the dif. of altitude $A - a$ will be as
the log. of D − log. of d, or as log. of $\frac{D}{d}$.

And if A = 0, or D the denſity at the ſurface of the earth, then any altitude above the ſurface a, is as the log. of $\frac{D}{d}$. Or, in general, the log. of $\frac{D}{d}$ is as the altitude of the one place above the other, whether the lower place be at the ſurface of the earth, or any where elſe.

And from this property is derived the method of determining the heights of mountains, and other eminences, by the barometer, which is an inſtrument that meaſures the weight or denſity of the air at any place. For by taking with this inſtrument, the preſſure or denſity at the foot of a hill for inſtance, and again at the top of it, the difference of the logarithms of theſe two preſſures, or the logarithms of their quotient, will be as the difference of altitude, or as the height of the hill; ſuppoſing the temperatures of the air to be the ſame at both places, and the gravity of air not altered by the different diſtances from the earth's centre.

But as this formula expreſſes only the relations between different altitudes, with reſpect to their denſities, recourſe muſt be had to ſome experiment, to obtain the real altitude which correſponds to any given denſity, or the denſity which correſponds to a given altitude. Now there are various experiments by which this may be done. The firſt, and moſt natural, is that which reſults from the known ſpecific gravity of air, with reſpect to the whole preſſure of the atmoſphere on the ſurface of the earth. Now, as the altitude a is always as log. $\frac{D}{d}$, aſſume h ſo that a may be $= h \times$ log. $\frac{D}{d}$, where h will be of one conſtant value for all altitudes; and to determine that value, let a caſe be taken in which we know the altitude a correſponding to a known denſity d: as for inſtance take $a = 1$ foot, or 1 inch, or ſome ſuch ſmall altitude; and becauſe the denſity D may be meaſured by the preſſure of the atmoſphere, or the uniform column of 27600 feet, when the temperature is 55°; therefore 27600 feet will denote the denſity D at the lower place, and 27599 the leſs denſity d at one foot above it; conſequently this equation ariſes, viz, $1 = h \times$ log. of $\frac{27600}{27599}$, which, by the nature of logarithms, is nearly $= h \times \frac{\cdot 43429448}{27600} = \frac{h}{63551}$ nearly; and hence $h =$ 63451 feet; which gives for any altitude whatever, this general theorem, viz, $a =$.

63551 × log. $\frac{D}{d}$, or $= 63551 \times$ log. $\frac{M}{m}$ feet, or 10592 × log. $\frac{M}{m}$ fathoms; where M is the column of mercury which is equal to the preſſure or weight of the atmoſphere at the bottom, and m that at the top of the altitude a; and where M and m may be taken in any meaſure, either feet, or inches, &c.

Note, that this formula is adapted to the mean temperature of the air 55°. But for every degree of temperature different from this, in the medium between the temperatures at the top and bottom of the altitude a, that altitude will vary by its 435th part; which muſt be added when the medium exceeds 55°, otherwiſe ſubtracted.

Note alſo, that a column of 30 inches of mercury varies its length by about the 320th part of an inch for every degree of heat, or rather the 9600th part of the whole volume.

But the ſame formula may be rendered much more convenient for uſe, by reducing the factor 10592 to 10000, by changing the temperature proportionably from 55°: thus, as the difference 592 is the 18th part of the whole factor 10592; and as 18 is the 24th part of 435; therefore the correſponding change of temperature is 24°, which reduces the 55° to 31°. So that the formula becomes $a = 10000 \times$ log. of $\frac{M}{m}$ fathoms when the temperature is 31 degrees; and for every degree above that, the reſult muſt be increaſed by ſo many times its 435th part.

See more on this head under the article BAROMETER, at the end.

By the weight and preſſure of the atmoſphere, the effect and operations of Pneumatic engines may be accounted for, and explained; ſuch as ſyphons, pumps, barometers, &c. See each of theſe articles, alſo AIR.

PNEUMATIC *Engine*, the ſame as the AIR-PUMP.

POCKET *Electrical Apparatus*.—This is a contrivance of Mr. William Jones, in Holborn, the form of which is repreſented in plate xxiii, fig. 4.

This ſmall machine is capable of a tolerably ſtrong charge, or accumulation of electricity, and will give a ſmall ſhock to one, two, three, or a greater number of perſons.

A is the Leyden phial or jar that holds the charge. B is the diſcharger to diſcharge the jar when required without electrifying the perſon that holds it. C is a ribbon prepared in a peculiar manner ſo as to be excited, and communicate its electricity to the jar. D are two hair, &c, ſkin rubbers, which are to be placed on the firſt and middle fingers of the left hand.

To charge the Jar.

Place the two finger-caps D on the firſt and middle finger of the left hand; hold the jar A at the ſame time, at the joining of the red and black on the outſide between the thumb and firſt finger of the ſame hand; then take the ribbon in your right hand, and ſteadily and gently draw it upwards between the two rubbers D, on the two fingers; taking care at the ſame time, the braſs ball of the jar is kept nearly cloſe to the ribbon, while it is paſſing through the fingers. By repeating this operation twelve or fourteen times, the electrical fire will paſs into the jar which will become charged, and by placing the diſcharger C againſt it, as in the plate, you will ſee a ſenſible ſpark paſs from the ball of the jar to that of the diſcharger. If the apparatus is dry and in good order, you will hear the crackling of the fire when the ribbon is paſſing through the fingers, and the jar will diſcharge at the diſtance repreſented in the figure.

To electrify a Perſon.

You muſt deſire him to take the jar in one hand, and with the other touch the nob of it: or, if diverſion is intended, deſire the perſon to ſmell at the nob of it, in expectation of ſmelling the ſcent of a roſe or a pink; this laſt mode has occaſioned it to be ſometimes called the Magic Smelling Bottle.

POETICAL *Numbers*. See NUMBERS.

POETICAL *Riſing* and *Setting*. See RISING and SETTING.

The ancient poets, referring the riſing and ſetting of the ſtars to that of the ſun, make three kinds of riſing and ſetting, viz, Coſmical, Acronical, and Heliacal. See each of theſe words in its place.

POINT, a term uſed in various arts and ſciences.

POINT, in Architecture. Arches of the third Point, and Arches of the fourth Point. See ARCHES.

POINT, in Aſtronomy, is a term applied to certain parts or places marked in the heavens, and diſtinguiſhed by proper epithets.

The four grand points or diviſions of the horizon, viz, the eaſt, weſt, north, and ſouth, are called the Cardinal Points.—The zenith and nadir are the Vertical Points.—The Points where the orbits of the planets cut the plane of the ecliptic, are called the Nodes.—The Points where the ecliptic and equator interſect, are called the Equinoctial Points. In particular, that where the ſun aſcends towards the north pole is called the Vernal Point; and that where he deſcends towards the ſouth, the Autumnal Point.—The higheſt and loweſt Points of the ecliptic are called the Solſtitial Points. Particularly, the former of them the Eſtival or Summer Point; the latter, the Brumal or Winter Point.

POINTS, in Electricity, are thoſe acute terminations of bodies which facilitate the paſſage of the electrical fluid either *from* or *to* ſuch bodies.

Mr. Jallabert was probably the firſt perſon who obſerved that a body pointed at one end, and round at the other, produced different appearances upon the ſame body, according as the pointed or round end was preſented to it. But Dr. Franklin firſt obſerved and evinced the whole effect of pointed bodies, both in drawing and throwing off electricity at greater diſtances than other bodies could do it; though he candidly acknowledges, that the power of Points to throw off the electric fire was communicated to him by his friend Mr. Thomas Hopkinſon.

Dr. Franklin electrified an iron ſhot, 3 or 4 inches in diameter, and obſerved that it would not attract a thread when the Point of a needle, communicating with the earth, was preſented to it; and he found it even impoſſible to electrify an iron ſhot when a ſharp needle lay upon it. This remarkable property, poſſeſſed by pointed bodies, of gradually and ſilently receiving or throwing off the electrie fluid, has been evinced by a variety of other familiar experiments.

Thus, if one hand be applied to the outſide coating of a large jar fully charged, and the Point of a needle held in the other, be directed towards the knob of the jar, and moved gradually near it, till the Point of the needle touch the knob or ball, the jar will be entirely diſcharged, ſo as to give no ſhock at all, or one that is hardly ſenſible. In this caſe the Point of the needle has gradually and ſilently drawn away the ſuperabundant electricity from the electrified jar.

Farther, if the knob of a braſs rod be held at ſuch a diſtance from the prime conductor, that ſparks may eaſily eſcape from the latter to the former, whilſt the machine is in motion; then if the Point of a needle be preſented, though at twice the diſtance of the rod from the conductor, no more ſparks will be ſeen paſſing to the rod. When the needle is removed, the ſparks will be ſeen; but upon preſenting it again, they will again diſappear. So that the Point of the needle draws off ſilently almoſt all the fluid, which is thrown by the cylinder or globe of the machine upon the prime conductor. This experiment may be varied, by fixing the needle upon the prime conductor with the point upward; and then, though the knob of a diſcharging rod, or the knuckle of the finger, be brought very near the prime conductor, and the excitation be very ſtrong, little or no ſpark will be perceived.

The influence of points is alſo evinced in the amuſing experiment, commonly called the electrical horſe-race, and many others. See THUNDER-*houſe*.

The late Mr. Henly exhibited the efficacy of pointed bodies, by ſuſpending a large bladder, well blown, and covered with gold, ſilver, or braſs leaf, by means of gum-water, at the end of a ſilken thread 6 or 7 feet long, hanging from the cieling of a room, and electrifying the bladder by giving it a ſtrong ſpark with the knob of a charged bottle: upon preſenting to it the knob of a wire, it cauſed the bladder to move towards the knob, and when nearly in contact gave it a ſpark, thus diſcharging its electricity. By giving the bladder another charge, and preſenting the Point of a needle to it, the bladder was not attracted by the Point, but

rather receded from it, eſpecially when the needle was ſuddenly preſented towards it.

But experiments evincing the efficacy of pointed bodies for ſilently receiving or throwing off the electric fluid, may be infinitely diverſified, according to the fancy or convenience of the electrician.

It may be obſerved, that in the caſe of points throwing off or receiving electricity, a current of air is ſenſible at an electrified Point, which is always in the direction of the Point, whether the electricity be poſitive or negative. A fact which has been well aſcertained by many electricians, and particularly by Dr. Prieſtley and Sig. Beccaria. The former contrived to exhibit the influence of this current on the flame of a candle, preſented to a pointed wire, electrified negatively, as well as poſitively. The blaſt was in both caſes alike, and ſo ſtrong as to lay bare the greateſt part of the wick, the flame being driven from the Point; and the effect was the ſame whether the electric fluid iſſued out of the Point or entered into it. He farther evinced this phenomenon by means of thin light vanes; and he found, as Mr. Wilſon had before obſerved, that the vanes would not turn in vacuo, nor in a cloſe unexhauſted receiver where the air had no free circulation. And in much the ſame manner, Beccaria exhibited to ſenſe the influence of the wind or current of air driven from points.

As to the *Theory* of the phenomena of Points, theſe are accounted for in a variety of ways, by different authors, though perhaps by none with perfect ſatisfaction. See Franklin's writings on Electricity; Lord Mahon's Principles of Electricity, 1779; Beccaria's Artificial Electricity, 1776, pa. 331; and Prieſtley's Hiſtory of Electricity, vol. 2, pa. 191, edit. 1775.

As to the *Application* of the doctrine of Points; it may be obſerved that there is not a more important fact in the hiſtory of electricity, than the uſe to which the diſcovery of the efficacy of pointed bodies has been applied.

Dr. Franklin, having aſcertained the identity of electricity and lightning, was preſently led to propoſe a cheap and eaſy method of ſecuring buildings from the damage of lightning, by fixing a pointed metal rod higher than any part of the building, and communicating with the ground, or with the neareſt water. And this contrivance was actually executed in a variety of caſes; and has uſually been thought an excellent preſervative againſt the terrible effects of lightning.

Some few inſtances however having occurred, in which buildings have been ſtruck and damaged, though provided with theſe conductors; a controverſy aroſe with regard to their expediency and utility. In this controverſy Mr. Benjamin Wilſon took the lead, and Dr. Muſgrave, and ſome few other electricians, the leaſt acquainted with the ſubject, concurred with him in their oppoſition to pointed elevated conductors. Theſe alledge, that every Point, as ſuch, ſolicits the lightning, and thus contributes not only to increaſe the quantity of every actual diſcharge, but alſo frequently to occaſion a diſcharge when it might not otherwiſe have happened: whereas, ſay they, if inſtead of pointed conductors, thoſe with blunted terminations were uſed, they would as effectually anſwer the purpoſe of conveying away the lightning ſafely, without the ſame tendency to increaſe or invite it. Accordingly, Mr. Wilſon, in a letter to the marquis of Rockingham (Philoſ. Tranſ. vol. 54, art. 44), expreſſes his opinion, that, in order to prevent lightning from doing miſchief to high buildings, large magazines, and the like, inſtead of the elevated external conductors, that, on the inſide of the higheſt part of ſuch building, and within a foot or two of the top, it may be proper to fix a rounded bar of metal, and to continue it down along the ſide of the wall to any kind of moiſture in the ground.

On the other hand, it is urged by the advocates for pointed conductors, that Points, inſtead of increaſing an actual diſcharge, really prevent a diſcharge where it would otherwiſe happen, and that blunted conductors tend to invite the clouds charged with lightning. And it ſeems to be a certain fact, that though a ſharp Point will draw off a charge of electricity ſilently at a much greater diſtance than a knob, yet a knob will be ſtruck with a full exploſion or ſhock, the charge being the ſame in both caſes, at a greater diſtance than a ſharp Point.

The efficacy of pointed bodies for preventing a ſtroke of lightning, is ingeniouſly explained by Dr. Franklin in the following manner:—An eye, he ſays, ſo ſituated as to view horizontally the underſide of a thunder-cloud, will ſee it very ragged, with a number of ſeparate fragments or ſmall clouds one under another; the loweſt ſometimes not far from the earth. Theſe, as ſo many ſtepping-ſtones, aſſiſt in conducting a ſtroke between a cloud and a building. To repreſent theſe by an experiment, he directs to take two or three locks of fine looſe cotton, and connect one of them with the prime conductor by a fine thread of 2 inches, another to that, and a third to the ſecond, by like threads, which may be ſpun out of the ſame cotton. He then directs to turn the globe, and ſays we ſhall ſee theſe locks extending themſelves towards the table, as the lower ſmall clouds do towards the earth; but that, on preſenting a ſharp Point, erect under the loweſt, it will ſhrink up to the ſecond, the ſecond up to the firſt, and all together to the prime conductor, where they will continue as long as the Point continues under them. May not, he adds, in like manner, the ſmall electrified clouds, whoſe equilibrium with the earth is ſoon reſtored by the Point, riſe up to the main body, and by that means occaſion ſo large a vacancy, as that the grand cloud cannot ſtrike in that place? Letters, pa. 121.

Mr. Henly too, as well as ſeveral other perſons, with a view of determining the queſtion, whether Points or knobs are to be preferred for the terminations of conductors, made ſeveral experiments, ſhewing in a variety of inſtances, the efficacy of Points in ſilently drawing off the electricity, and preventing ſtrokes which would happen to knobs in the ſame ſituation. Philoſ. Tranſ. vol. 64, part 2, art. 18. See alſo THUNDER-*Houſ*.

Indeed it has been univerſally allowed, that in caſes where the quantity of electricity, with which thunder-clouds are charged, is ſmall, or when they move ſlowly in their paſſage to and over a building, pointed conductors, which draw off the electrical fluid ſilently, within the diſtance at which rounded ends will explode, will gradually exhauſt them, and thus contribute to prevent a ſtroke and preſerve the buildings to which they are annexed.

But it has been ſaid by thoſe who are averſe to the uſe of ſuch conductors, that if clouds, of great extent, and highly electrified, ſhould be driven directly over them with great velocity, or if a cloud hanging directly over buildings to which they are annexed, ſuddenly receives a charge by exploſion from another cloud at a diſtance, ſo as to enable it inſtantly to ſtrike into the earth, theſe pointed conductors muſt take the exploſion; on account of their greater readineſs to admit electricity at a much greater diſtance than thoſe that are blunted, and in proportion to the difference of that ſtriking diſtance, do miſchief inſtead of good: and therefore, they add, that ſuch pointed conductors, though they may be ſometimes advantageous, are yet at other times prejudicial; and that, as the purpoſe for which conductors are fixed upon buildings, is not to protect them from one particular ſort of clouds only, but if poſſible from all, it cannot be adviſable to uſe that kind of conductors which, if they diminiſh danger on the one hand, will increaſe it on the other. Beſides, it is alleged, that if pointed conductors are attended with any the ſlighteſt degree of danger, that danger muſt be conſiderably augmented by carrying them high up into the air, and by fixing them upon every angle of a building, and by making them project in every direction. Such is the reaſoning of Dr. Muſgrave: ſee his paper in the Philoſ. Tranſ. vol. 68, part 2, art. 36.

Mr. Wilſon too, diſſenting from the report of a committee of the Royal Society, appointed to inſpect the damage done by lightning to the houſe of the Board of Ordnance, at Purfleet, in 1777, was led to juſtify his diſſent, and to diſparage the uſe of pointed and elevated conductors, by means of a magnificent apparatus he conſtructed, with which he might produce effects ſimilar to thoſe that had happened in the caſe referred to the conſideration and deciſion of the committee. With this view he procured a model of the Board-houſe at Purfleet, reſembling it as nearly as poſſible in every eſſential appendage, and furniſhed with conductors of different lengths and terminations. And to conſtruct a ſubſtitute for a cloud, he joined together the broad rims of 120 drums, forming together a cylinder of 155 feet in length, and above 16 inches in diameter; and this immenſe cylinder, of about 600 ſquare feet of coated ſurface, was connected occaſionally with one end of a wire 4800 feet long. As this bulky apparatus, repreſenting the thunder-cloud, could not conveniently be put in motion, he contrived to accompliſh the ſame end by moving the model of the building, with a velocity anſwering to that of the cloud, which he ſtates, at a moderate computation, to be about 4 or 5 miles an hour. This apparatus was charged by a machine with one glaſs cylinder, about 10 or 11 feet from its neareſt end; and the whole of the apparatus was diſpoſed in the great room of the Pantheon, and applied to uſe in a variety of experiments. But it is impoſſible within the limits of this article to do juſtice to Mr. Wilſon's experiments, or to the inferences which he deduces from them. Suffice it juſt to obſerve, that moſt of his experiments, in which the model of the houſe, which was paſſed ſwiftly under the artificial cloud, and having annexed to it either the pointed or blunt conductors at the ſame or different heights, were intended to ſhew, that pointed conductors are ſtruck at a greater diſtance, and with a higher elevation, than the blunted ones: and from all his experiments made with pointed and rounded conductors, provided the circumſtances be the ſame in both, he infers, that the rounded ones are much the ſafer of the two; whether the lightning proceeds from one cloud or from ſeveral; that thoſe are ſtill ſafer which riſe little or nothing above the higheſt part of the building; and that this ſafety ariſes from the greateſt reſiſtance exerted at the larger ſurface. See Philoſ. Tranſ. for 1778, pa. 232.

The committee of the Royal Society however, which was compoſed of nine of the moſt diſtinguiſhed electricians in the kingdom, and to whom was referred the conſideration of the moſt effectual method of ſecuring the powder-magazines at Purfleet againſt the effects of lightning, expreſs their united opinion, that elevated ſharp rods, conſtructed and diſpoſed in the manner which they direct, are preferable to low conductors terminated in rounded ends, knobs, or balls of metal; and that the experiments and reaſonings, made and alleged to the contrary by Mr. Wilſon, are inconcluſive.

Mr. Nairne alſo, in order to obviate the objections of Mr. Wilſon and others, and to vindicate the preference generally given to high and pointed conductors, conſtructed a much more ſimple apparatus than that of Mr. Wilſon, with which he made a number of well-deſigned and well-conducted experiments, which ſeem to prove the point as far as it is capable of being proved by an artificial electrical apparatus. From theſe laſt experiments it appears, that though the point was ſtruck by means of a ſwift motion of the artificial cloud, yet a ſmall ball of 3 tenths of an inch diameter was ſtruck farther off than the Point, and a larger ball at a much greater diſtance than either, even with the ſwifteſt motion. Upon the whole, Mr. Nairne ſeems to be juſtified in preferring elevated pointed conductors; next to them, thoſe that are pointed, though they riſe but little above the higheſt part of a building; and after them, thoſe that are terminated in a ball, and placed even with the higheſt part of the building. See Philoſ. Tranſ. 1778, pa. 823.

On the other part, Dr. Muſgrave, not yet ſatisfied, gave in another paper, being "Reaſons for diſſenting from the Report of the Committee appointed to conſider of Mr. Wilſon's Experiments; including Remarks on ſome Experiments exhibited by Mr. Nairne;" which is inſerted, by miſtake, before Mr. Nairne's paper, being at pa. 801 of the ſame volume.

And farther, Mr. Wilſon has another paper, on the ſame ſubject, at pa. 999 of the ſame vol. of Philoſ. Tranſ. for 1778, entitled, "New Experiments upon the Leyden Phial, reſpecting the termination of conductors;" repeating and aſſerting his former objections and reaſonings.

In the Philoſ. Tranſ. too for 1779, pa. 454, Mr. William Swift has a paper, farther proſecuting this ſubject; making various experiments with ſimple and ingenious machinery, with models of houſes and clouds, and with various ſorts of conductors. From the experiments he infers in general, that "the whole current

of theſe experiments tends to ſhew the preference of Points to balls, in order to diminiſh and draw off the electric matter when excited, or to prevent it from accumulating; and conſequently the propriety or even neceſſity of terminating all conductors with Points, to make them uſeful to prevent damage to buildings from lightning. Nay the very conſtruction of all electrical machines, in which it is neceſſary to round all the parts, and to avoid making edges and points which would hinder the matter from being excited, will, I imagine, on reflection, be another corroborating proof of the reſult of the experiments themſelves."

There were other communications made to the Royal Society upon the important ſubject of conductors, ſome of which were received, and others rejected. Upon the whole, this conteſt turned out one of the moſt extraordinary that ever was agitated in the Society; producing the moſt remarkable diſputes, differences, and ſtrange conſequences, that ever the Society experienced ſince it had exiſtence; conſequences which manifeſted themſelves in various inſtances for many years after, and which continue to this very day. All which, with the various ſecret ſprings and aſtoniſhing intrigues, may probably be given to the public on ſome other occaſion.

Point, in Geometry, according to Euclid, is that which has no parts, or is indiviſible; being void of all extenſion, both as to length, breadth, and depth.

This is what is otherwiſe called the Mathematical Point, being the interſection of two lines, and is only conceived by the imagination; yet it is in this that all magnitude begins and ends; the extremes of a line being Points; the extremes of a ſurface, Lines; and the extremes of a ſolid, Surfaces. And hence ſome define a Point, the inceptive of magnitude.

Proportion of Mathematical Points. It is a popular maxim, that all infinites are equal; yet is the maxim falſe, whether of quantities infinitely great, or infinitely little. Dr. Halley inſtances in ſeveral infinite quantities which are in a finite proportion to each other; and ſome that are infinitely greater than others. See Infinite *Quantity*.

And the ſame is ſhewn by Mr. Robarts, of infinitely ſmall quantities, or mathematical Points. He demonſtrates, for inſtance, that the Points of contact between circles and their tangents, are in the ſubduplicate ratio of the diameters of the circles; that the Point of contact between a ſphere and a plane is infinitely greater than between a circle and a line; and that the Points of contact in ſpheres of different magnitudes, are to each other as the diameters of the ſpheres. Philoſ. Tranſ. vol. 27, pa. 470.

Conjugate Point, is uſed for that Point into which the conjugate oval, belonging to ſome kind of curves, vaniſhes. Maclaurin's Alg. pa. 308.

Point *of Contrary Flexure*, &c. See Inflexion, Retrogradation or Retrogression, &c, of curves.

Points *of the Compaſs*, or *Horizon*, &c, in Geography and Navigation, are the Points of diviſion when the whole circle, quite around, is divided into 32 equal parts. Theſe Points are therefore at the diſtance of the 32d part of the circle, or 11° 15′, from each other; hence 5° 37′½ is the diſtance of the half points, and 2° 48′¾ is the diſtance of the quarter Points. See Compass. The principal of theſe are the four cardinal Points, eaſt, weſt, north and ſouth.

Point is alſo uſed for a cape or headland, jutting out into the ſea.——The ſeamen ſay two Points of land are one in another, when they are in a right line, the one behind the other.

Point, in Optics. As the

Point *of Concourſe* or *Concurrence*, is that in which converging rays meet; and is uſually called focus.

Point of *Diſperſion*, *Incidence*, *Reflection*, *Refraction*, and *Radiant* Point. See theſe ſeveral articles.

Point, in Perſpective, is a term uſed for various parts or places, with regard to the perſpective plane. As, the

Point *of Sight*, or *of the eye*, called alſo the Principal Point, is the Point on a plane where a perpendicular from the eye meets it. See Perspective.

Some authors, however, by the Point of Sight, or Viſion, mean the Point where the eye is actually placed, and where all the rays terminate. See Perspective.

Point *of Diſtance*, is a Point in a horizontal line, at the ſame diſtance from the principal Point as the eye is from the ſame. See Perspective.

Third Point, is a Point taken at diſcretion in the line of diſtance, where all the diagonals meet that are drawn from the diviſions of the geometrical plane.

Objective Point, is a Point on a geometrical plane, whoſe repreſentation on the perſpective plane is required.

Accidental Point, and *Viſual* Point. See Accidental and Visual.

Point *of View*, with regard to Building, Painting, &c, is a Point at a certain diſtance from a building, or other object, where the eye has the moſt advantageous view or proſpect of the ſame. And this Point is uſually at a diſtance equal to the height of the building.

Point, in Phyſics, is the ſmalleſt or leaſt ſenſible object of ſight, marked with a pen, or point of a compaſs, or the like. This is popularly called a Phyſical Point, and of ſuch does all phyſical magnitude conſiſt.

Point-Blanc, *Point-Blank*, in Gunnery, denotes the horizontal or level poſition of a gun, or having its muzzle neither elevated nor depreſſed. And the Point-blanc range, is the diſtance the ſhot goes, before it ſtrikes the level ground, when diſcharged in the horizontal or Point-blanc direction. Or ſometimes this means the diſtance the ball goes horizontally in a ſtraight-lined direction.

Pointing, in Artillery and Gunnery, is the laying a piece of ordnance in any propoſed direction, either horizontal, or elevated, or depreſſed, to any angle. This is uſually effected by means of the gunner's quadrant, which, being applied to, or in, the muzzle of the piece, ſhews by a plummet the degree of elevation or depreſſion.

Pointing, in Navigation, is the marking on the chart in what Point, or place, the veſſel is.——This is done by means of the latitude and longitude, after theſe are known, or found by obſervation or computation. Thus, draw a line, with a pencil, across the chart according to the latitude; and another across the other way according to the longitude; then the interſection

ſection of theſe two lines, is the Point or place on the chart where the ſhip is; which is then marked black with a pen, and the pencil lines rubbed out. From the Point or place, thus found, the chart readily ſhews the direct diſtance and courſe run, as alſo yet to run to the intended port, &c.

POLAR, ſomething that relates to the poles of the world: as polar virtue, polar tendency.

POLAR *Circles*, are two leſſer circles of the ſphere, or globe, one round each pole, and at the ſame diſtance from it as is equal to the ſun's greateſt declination or the obliquity of the ecliptic; that is, at preſent 23° 28′.—The ſpace included within each polar circle, is the frigid zone; and to every part of this ſpace, the ſun never ſets at ſome time of the year, and never riſes at another time; each of theſe being a longer duration as the place is nearer the pole.

POLAR *Dials*, are ſuch as have their planes parallel to ſome great circle paſſing through the poles, or to ſome one of the hour-circles; ſo that the pole is neither elevated above the plane, nor depreſſed below it.—This dial, therefore, can have no centre; and conſequently its ſtyle, ſubſtyle, and hour-lines, are parallel.—This will therefore be an horizontal dial to thoſe who live at the equator.

POLAR *Projection*, is a repreſentation of the earth, or heavens, projected on the plane of one of the polar circles.

POLAR *Regions*, are thoſe parts of the earth which lie near the north and ſouth poles.

POLARITY, the quality of a thing having poles, or pointing to, or reſpecting ſome pole: as the magnetic needle, &c.

By heating an iron bar, and letting it cool again in a vertical poſition, it acquires a polarity, or magnetic virtue: the lower end becoming the north pole, and the upper end the ſouth pole. But iron bars acquire a polarity by barely continuing a long time in an erect poſition, even without heating them. Thus, the upright iron bars of ſome windows, &c, are often found to have poles: Nay, an iron rod acquires a polarity, by the mere holding it erect; the lower end, in that caſe, attracting the ſouth end of a magnetic needle; and the upper, the north end. But theſe poles are mutable, and ſhift with the ſituation of the rod.

Some modern writers, particularly Dr. Higgins, in his Philoſophical Eſſay concerning Light, have maintained the polarity of the parts of matter, or that their ſimple attractions are more forcible in one direction, or axis of each atom, than in any other.

POLES, in Aſtronomy, the extremities of the axis upon which the whole ſphere of the world revolves; or the points on the ſurface of the ſphere through which the axis paſſes. Theſe are on every ſide at the diſtance of a quadrant, or 90°, from every point of the equinoctial, and are called, by way of eminence, the poles of the world. That which is viſible to us in Europe, or raiſed above our horizon, is called the Arctic or North Pole; and its oppoſite one, the Antarctic or South Pole.

POLES, in Geography, are the extremities of the earth's axis; or the points on the ſurface of the earth through which the axis paſſes. Of which, that elevated above our horizon is called the Arctic or North Pole; and the oppoſite one, the Antarctic or South Pole.

In conſequence of the ſituation of the Poles, with the inclination of the earth's axis, and its parallelism during the annual motion of our globe round the ſun, the Poles have only one day and one night throughout the year, each being half a year in length. And becauſe of the obliquity with which the rays of the ſun fall upon the polar regions, and the great length of the night in the winter ſeaſon, it is commonly ſuppoſed the cold is ſo intenſe, that thoſe parts of the globe which lie near the Poles have never been fully explored, though the attempt has been repeatedly made by the moſt celebrated navigators. And yet Dr. Halley was of opinion, that the ſolſtitial day, at the Pole, is as hot as at the equator when the ſun is in the zenith; becauſe all the 24 hours of that day under the Pole the ſun-beams are inclined to the horizon in an angle of 23° 28′; whereas at the equator, though the ſun becomes vertical, yet he ſhines no more than 12 hours, being abſent the other 12 hours: and beſides, that during 3 hours 8 minutes of the 12 hours which he is above the horizon there, he is not ſo much elevated as at the Pole. Experience however ſeems to ſhew that this opinion and reaſoning of Dr. Halley are not well founded: for in all the parts of the earth that we know, the middle of ſummer is always the leſs hot the farther the place is from the equator, or the nearer it is to the Pole.

The great object for which navigators have ventured themſelves in the frozen ſeas about the north pole, was to find out a more quick and ready paſſage to the Eaſt Indies. And this has been attempted three ſeveral ways: one by coaſting along the northern parts of Europe and Aſia, called the north-eaſt paſſage; another, by ſailing round the northern part of the American continent, called the north-weſt paſſage; and the third, by ſailing directly over the pole itſelf.

The poſſibility of ſucceeding in the north-eaſt was for a long time believed; and in the laſt century many navigators, particularly the Hollanders, attempted it with great fortitude and perſeverance. But it was always found impoſſible to ſurmount the obſtacles which nature had thrown in the way; and ſubſequent attempts have in a manner demonſtrated the impoſſibility of ever ſailing eaſtward along the northern coaſt of Aſia. The reaſon of this impoſſibility is, that in proportion to the extent of land, the cold is always greater in winter, and vice verſa. This is the caſe even in temperate climates; but much more ſo in thoſe frozen regions when the ſun's influence, even in ſummer, is but ſmall. Hence, as the continent of Aſia extends a vaſt way from weſt to eaſt, and has beſides the continent of Europe joined to it on the weſt, it follows, that about the middle part of that tract of land the cold ſhould be greater than any where elſe. Experience has determined this to be fact; and it now appears, that about the middle of the northern part of Aſia, the ice never thaws; neither have even the hardy Ruſſians and Siberians themſelves been able to overcome the difficulties they meet with in that part of their voyages.

With regard to the north-weſt paſſage, the ſame difficulties occur as in the other. According to Captain Cook's voyage, it appears that if there is any ſtrait which

which divides the continent of America into two, it muſt lie in a higher latitude than 70°, and conſequently be perpetually frozen up. And therefore if a north-weſt paſſage can be found, it muſt be by ſailing round the whole American continent, inſtead of ſeeking a paſſage through it, which ſome have ſuppoſed to exiſt in the bottom of Baffin's Bay. But the extent of the American continent to the northward is yet unknown; and there is a poſſibility of its being joined to that part of Aſia between the Piaſida and Chatanga, which has never yet been circumnavigated. Indeed a rumour has lately gone abroad of ſome remarkable inlet being obſerved on the weſtern coaſt of North America, which it is gueſſed may poſſibly lead to ſome communication with the eaſtern ſide, by the lakes, or a paſſage into Hudſon's Bay: but there ſeems little or no probability of any ſucceſs this way, in which many fruitleſs attempts have been made at various times. It remains therefore to conſider, whether there is any probability of attaining the wiſhed-for paſſage by ſailing directly north, between the eaſtern and weſtern continents.

The late celebrated mathematician, Mr. Maclaurin, was ſo fully perſuaded of the practicability of paſſing by this way to the South and Indian ſeas, that he uſed to ſay, if his other avocations would permit, he would undertake the voyage of trial, even at his own expence.

The practicability of this method, which would lead directly to the Pole itſelf, has alſo been ingeniouſly ſupported by Mr. Daines Barrington, in ſome tracts publiſhed in the years 1775 and 1776, in conſequence of the unſucceſsful attempt made by captain Phipps in the year 1773, to reach a higher northern latitude than 81°. Mr. Barrington inſtances a great number of navigators who have reached very high northern latitudes; nay, ſome who have been at the Pole itſelf, or gone beyond it. From all which he concludes, that if the voyage be attempted at a proper time of the year, there would not be any great difficulty in reaching the Pole. Thoſe vaſt pieces of ice which commonly obſtruct the navigators, he thinks, proceed from the mouths of the great Aſiatic rivers which run northward into the frozen ocean, and are driven eaſtward and weſtward by the currents. But, though we ſhould ſuppoſe them to come directly from the Pole, ſtill our author thinks that this affords an undeniable proof that the Pole itſelf is free from ice; becauſe, when the pieces leave it, and come to the ſouthward, it is impoſſible that they can at the ſame time accumulate at the Pole.

The Altitude or Elevation of the POLE, is an arch of the meridian intercepted between the Pole and the horizon of any places, and is equal to the latitude of the place.

To obſerve the Altitude of the POLE. With a quadrant, obſerve both the greateſt and leaſt meridian altitude of the Pole ſtar. Then half the ſum of the two altitudes, will be the height of the Pole, or the latitude of the place; and half the difference of the ſame will be the diſtance of the ſtar from the Pole. But, for accuracy, the obſerved altitudes ſhould be corrected on account of refraction, before their ſum or difference is taken. See REFRACTION.

POLE, in Spherics, or the Pole of a great circle, is a point upon the ſphere equally diſtant from every part of the circumference of the great circle; or a point 90° diſtant from the circumference in any part of it.—The zenith and nadir are the Poles of the horizon; and the Poles of the equator are the ſame with thoſe of the ſphere or globe.

POLES, in Magnetics, are two points in a loadſtone, correſponding to the Poles of the world; one pointing to the north, and the other to the ſouth.

If the ſtone be broken in ever ſo many pieces, every fragment will ſtill have its two Poles. And if a magnet be biſected by a plane perpendicular to the axis; the two points before joined will become oppoſite Poles, one in each ſegment.

To touch a needle, &c, with a magnet, that part intended for the north end is touched with the ſouth Pole of the magnet; and that intended for the ſouth end, with the north Pole; for the Poles of the needle become contrary to thoſe of the magnet.

A piece of iron acquires a polarity by only holding it upright; though its Poles are not fixed, but ſhift, and are inverted as the iron is. Fire deſtroys all fixed Poles; but it ſtrengthens the mutable ones.

Dr. Gilbert ſays, the end of a rod being heated, and left to cool pointing northward, it becomes a fixed north Pole; if ſouthward, a fixed ſouth Pole. When the end is cooled, held downward, it acquires rather more magnetiſm than if cooled horizontally towards the north. But the beſt way is to cool it a little inclined to the north. Repeating the operations of heating and cooling does not increaſe the effect.

Dr. Power ſays, if a rod be held northwards, and the north end be hammered in that poſition, it will become a fixed north Pole; and contrarily if the ſouth end be hammered. The heavier the blows are, cæteris paribus, the ſtronger will the magnetiſm be; and a few hard blows have as much effect as a great number. And what is ſaid of hammering, is to be likewiſe underſtood of filing, grinding, ſawing, &c; nay, a gentle rubbing, when long continued, will produce Poles.

Old punches and drills have all fixed north poles; becauſe they are almoſt conſtantly uſed downwards. New drills have either mutable Poles, or weak north ones. Drilling with ſuch a one ſouthward horizontally, it is a chance if you produce a fixed ſouth Pole; much leſs if you drill ſouth downwards; but by drilling ſouth upwards, you always make a fixed ſouth Pole.

Mr. Ballard ſays, that in 6 or 7 drills, made in his preſence, the bit of each became a north Pole, merely by hardening.

A weak fixed Pole may degenerate into a mutable one in a day, or even in a few minutes, by holding it in a poſition contrary to its pole. The loadſtone itſelf will not make a fixed Pole in every piece of iron: if the iron be thick, it is neceſſary that it have ſome conſiderable length.

POLE *of a Glaſs*, in Optics, is the thickeſt part of a convex glaſs, or the thinneſt part of a concave one; being the ſame as what is otherwiſe called the vertex of the glaſs; and which, when truly ground, is exactly in the middle of its ſurface.

POLE, or *Rod*, in Surveying, is a lineal meaſure containing $5\frac{1}{2}$ yards, or $16\frac{1}{2}$ feet.—The ſquare of it is called a ſquare Pole; but more uſually a perch, or a rod.

POLE-

POLE-STAR, is a ſtar of the 2d magnitude near the north Pole, in the end of the tail of Urſa Minor, or the Little Bear. Its mean place in the heavens for the beginning of 1790, was as follows: viz,

Right Aſcenſion - -	12°	31′	47″
Annual variat. in ditto -	0	3	4
Declination - -	88	11	8
Annual variat. in ditto -	0	0	$19\frac{6}{10}$

The nearneſs of this ſtar to the Pole, on which account it is always above the horizon in theſe northern latitudes, makes it very uſeful in Navigation, &c, for determining the meridian line, the elevation of Pole, and conſequently the latitude of the place, &c.

POLEMOSCOPE, in Optics, an oblique kind of proſpective glaſs, contrived for the ſeeing of objects that do not lie directly before the eye. It was invented by Hevelius, in 1637, and is the ſame as OPERA *Glaſs*; which ſee.

POLITICAL *Arithmetic*, the application of arithmetical calculations to political uſes and ſubjects; ſuch as the public revenues, the number of people, the extent and value of lands, taxes, trade, commerce, or whatever relates to the power, ſtrength, riches, &c, of a nation or commonwealth. Or, as Davenant conciſely defines it, the art of reaſoning by figures, upon things relating to government.

The chief authors who have attempted calculations of this kind, are, Sir William Petty, Major Graunt, Dr. Halley, Dr. Davenant, Mr. King, and Dr. Price.

Sir William Petty, among many other articles, ſtates that, in his time, the people in England were about ſix millions, and their annual expence about 7l. each; that the rent of the lands was about eight millions, and the intereſts and profits of the perſonal eſtates as much; that the rent of the houſes in England was four millions, and the profits of the labour of all the people twenty-ſix millions yearly; that the corn uſed in England, at 5s. the buſhel for wheat, and 2s. 6d. for barley, amounts to ten millions per annum; that the navy of England required 36,000 men to man it, and the trade and other ſhipping about 48,000; that the whole people in England, Scotland, and Ireland, together, were about nine millions and a half; and thoſe in France about thirteen millions and a half; and in the whole world about 350 millions; alſo that the whole caſh of England, in current money, was then about ſix millions ſterling. See his Political Arith. p. 74, &c.

Mr. Davenant gives ſome good reaſons why many of Sir W. Petty's numbers are not to be entirely depended on; and advances others of his own, founded on the obſervations of Mr. Greg. King. Some of the particulars are, that the land of England is thirty-nine millions of acres; that the number of people in London was about 530,000, and in all England five millions and a half, increaſing 9000 annually, or about the 600th part; the yearly rent of the lands ten millions, and that of the houſes two millions; the produce of all kinds of grain 9 millions. Davenant's Eſſay upon the probable methods &c, in his works, vol. 6.

Major Graunt, in his obſervations on the bills of mortality, computes, that there are 39,000 ſquare miles of land in England, or 25 million acres in England and Wales, and 4,600,000 perſons, making about 5 acres and a half to each perſon; that the people of London were 640,000; and ſtates the ſeveral numbers of perſons living at the different ages.

Sir William Petty, in his diſcourſe about duplicate proportion, farther ſtates, that it is found by experience, that there are more perſons living between 16 and 26 than of any other age; and from thence he infers, that the ſquare roots of every number of men's ages under 16, whoſe root is 4, ſhew the proportion of the probability of ſuch perſons reaching the age of 70 years: thus, the probability of reaching that age by perſons of the

ages of 16, 9, 4, and 1,
are as 4, 3, 2, 1, reſpectively.

Alſo that the probabilities of their order of dying, at ages above that, are as the ſquare-roots of the ages: thus, the probabilities of the order of dying firſt,

of the ages 16, 25, 36, &c,
are as the roots 4, 5, 6, &c.

that is, the odds are 5 to 4 that a perſon of 25 dies before one of 16, and ſo on, declining up to 70 years of age.

Dr. Halley has made a very exact eſtimation of the degrees of mortality of mankind, from a curious table of the births and burials, at the city of Breſlau, in Sileſia; with an attempt to aſcertain the price of annuities upon lives, and many other curious particulars. See the Philoſ. Tranſ. vol. 17, pa. 596. Another table of this kind is given by Mr. Simpſon, for the city of London; and ſeveral by Dr. Price, for many different places.

Mr. Kerſeboom, of Holland, has many and curious calculations and tables of the ſame kind. From his obſervations on the births of the people in England, it appears, that the number of males born, is in proportion to that of the females, as 18 to 17; and that the inhabitants living in Holland are in the ſame proportion.

Dr. Brackenridge has given an eſtimate of the number of people in England, formed both from the number of houſes, and alſo from the quantity of bread conſumed. Upon the former principle, he finds the number of houſes in England and Wales to be about 900,000; and, allowing 6 perſons to each houſe, the number of people near 5 millions and a half. And upon the latter principle, eſtimating the quantity of corn conſumed at home at 2 millions of quarters, and 3 perſons to every quarter of corn, makes the number of people 6 millions. See Philoſ. Tranſ. vol. 49, art. 45 and 113.

Dr. Derham, from a great number of regiſters of places, finds the proportions of the marriages to the births and burials; and Dr. Price has done the ſame for ſtill more places; the mediums of all which are,

	Marriages to Births, as
Dr. Derham -	1 to 4·7
Dr. Price -	1 to 3·9

See Philoſ. Tranſ. Abr. vol. 7, part 4, pa. 46; alſo Dr. Price's Obſervations on Reverſionary Payments; and the articles of this Dictionary, EXPECTATION *of Life*,

Life, LIFE-*Annuities*, MORTALITY, POPULATION, &c.

POLLUX, in Aſtronomy, the hind twin, or the poſterior part of the conſtellation Gemini.

POLLUX is alſo a fixed ſtar of the ſecond magnitude, in the conſtellation Gemini, or the Twins. See CASTOR and *Pollux*, alſo GEMINI.

POLYACOUSTICS, inſtruments contrived to multiply ſounds, as polyſcopes or multiplying glaſſes do the images of objects.

POLYEDRON. See POLYHEDRON.

POLYGON, in Geometry, a figure of many angles; and conſequently of many ſides alſo; for every figure has as many ſides as angles. If the angles be all equal among themſelves, the polygon is ſaid to be a regular one; otherwiſe, it is irregular. Polygons alſo take particular names according to the number of their ſides; thus a Polygon of

3 ſides is called a trigon,
4 ſides - a tetragon,
5 ſides - a pentagon,
6 ſides - a hexagon, &c.

and a circle may be conſidered as a Polygon of an infinite number of ſmall ſides, or as the limit of the Polygons.

Polygons have various properties, as below:

1. Every Polygon may be divided into as many triangles as it hath ſides.

2. The angles of any Polygon taken together, make twice as many right angles, wanting 4, as the figure hath ſides. Thus, if the Polygon has 5 ſides; the double of that is 10, from which ſubtracting 4, leaves 6 right angles, or 540 degrees, which is the ſum of the 5 angles of the pentagon. And this property, as well as the former, belongs to both regular and irregular Polygons.

3. Every regular Polygon may be either inſcribed in a circle, or deſcribed about it. But not ſo of the irregular ones, except the triangle, and another particular caſe as in the following property.

An equilateral figure inſcribed in a circle, is always equiangular.— But an equiangular figure inſcribed in a circle is not always equilateral, but only when the number of ſides is odd. For if the ſides be of an even number, then they may either be all equal; or elſe half of them may be equal, and the other half equal to each other, but different from the former half, the equals being placed alternately.

4. Every Polygon, circumſcribed about a circle, is equal to a right-angled triangle, of which one leg is the radius of the circle, and the other the perimeter or ſum of all the ſides of the Polygon. Or the Polygon is equal to half the rectangle under its perimeter and the radius of its inſcribed circle, or the perpendicular from its centre upon one ſide of the Polygon.

Hence, the area of a circle being leſs than that of its circumſcribing Polygon, and greater than that of its inſcribed Polygon, the circle is the limit of the inſcribed and circumſcribed Polygons: in like manner the circumference of the circle is the limit between the perimeters of the ſaid Polygons: conſequently the circle is equal to a right-angled triangle, having one leg equal to the radius, and the other leg equal to the circumference; and therefore its area is found by multiplying half the circumference by half the diameter. In like manner, the area of any Polygon is found by multiplying half its perimeter by the perpendicular demitted from the centre upon one ſide.

5. The following Table exhibits the moſt remarkable particulars in all the Polygons, up to the dodecagon of 12 ſides; viz, the angle at the centre AOB, the angle of the Polygon C or CAB or double of OAB, and the area of the Polygon when each ſide AB is 1. (See the following figure.)

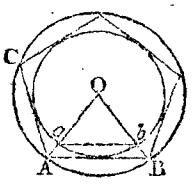
No. of ſides.	Name of Polygon.	Ang. O at cent.	Ang. C. of Polyg.	Area.
3	Trigon	120°	60°	0·4330127
4	Tetragon	90	90	1·0000000
5	Pentagon	72	108	1·7204774
6	Hexagon	60	120	2·5980762
7	Heptagon	$51\frac{3}{7}$	$128\frac{4}{7}$	3·6339124
8	Octagon	45	135	4·8284271
9	Nonagon	40	140	6·1818242
10	Decagon	36	144	7·6942088
11	Undecagon	$32\frac{8}{11}$	$147\frac{3}{11}$	9·3656399
12	Dodecagon	30	150	11·1961524

By means of the numbers in this Table, any Polygons may be conſtructed, or their areas found: thus,

(1ſt) *To inſcribe a Polygon in a given Circle.* At the centre make the angle O equal to the angle at the centre of the propoſed Polygon, found in the 3d column of the Table, the legs cutting the circle in A and B; and join A and B which will be one ſide of the Polygon. Then take AB between the compaſſes, and apply it continually round the circumference, to complete the Polygon.

(2d) *Upon the given Line* AB *to deſcribe a regular Polygon.* From the extremities draw the two lines AO and BO, making the angles A and B each equal to half the angle of the Polygon, found in the 4th column of the Table, and their interſection O will be the centre of the circumſcribed circle: then apply AB continually round the circumference as before.

(3d) *To deſcribe a Polygon about a given Circle.*— At the centre O make the angle of the centre as in the 1ſt art. its legs cutting the circle in *a* and *b*: join *ab*, and parallel to it draw AB to touch the circle: and meeting O*a* and O*b* produced in A and B: with the radius OA, or OB, deſcribe a circle, and around its circumference apply continual AB, which will complete the Polygon as before.



(4th) *To find the Area of any regular Polygon.*— Multiply the ſquare of its ſide by the tabular area, found on the line of its name in the laſt column of the Table, and the product will be the area. Thus, to

find the area of the trigon, or equilateral triangle, whose side is 20. The square of 20 being 400, multiply the tabular area 4330127 by 400, as in the margin, and the product 173·20508 will be the area.

0·4330127
400
173·2050800

6. There are several curious algebraical theorems for inscribing Polygons in circles, or finding the chord of any proposed part of the circumference, which is the same as angular sections. These kinds of sections, or parts and multiples of arcs, were first treated of by Vieta, as shewn in the Introduction to my Log. pa. 9, and since pursued by several other mathematicians, in whose works they are usually to be found. Many other particulars relating to Polygons may also be seen in my Mensuration, 2d edit. pa. 20, 21, 22, 23, 113, &c.

POLYGON, in Fortification, denotes the figure or perimeter of a fortress, or fortified place. This is either Exterior or Interior.

Exterior POLYGON is the perimeter or figure formed by lines connecting the points of the bastions to one another, quite round the work. And

Interior POLYGON, is the perimeter or figure formed by lines connecting the centres of the bastions, quite around.

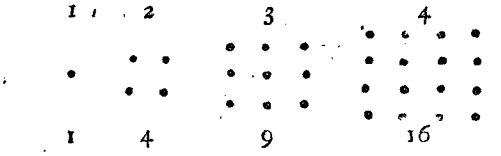
Line of POLYGONS, is a line on some sectors, containing the homologous sides of the first nine regular Polygons inscribed in the same circle; viz, from an equilateral triangle to a dodecagon.

POLYGONAL *Numbers*, are the continual or successive sums of a rank of any arithmeticals beginning at 1, and regularly increasing; and therefore are the first order of figurate numbers; they are called Polygonals, because the number of points in them may be arranged in the form of the several Polygonal figures in geometry, as is illustrated under the article FIGURATE *Numbers*, which see.

The several sorts of Polygonal numbers, viz, the triangles, squares, pentagons, hexagons, &c, are formed from the addition of the terms of the arithmetical series, having respectively their common difference 1, 2, 3, 4, &c; viz, if the common difference of the arithmeticals be 1, the sums of their terms will form the triangles; if 2, the squares; if 3, the pentagons; if 4, the hexagons, &c. Thus:

Arith. Progres.	1,	2,	3,	4,	5,	6,	7.
Triang. Nos.	1,	3,	6,	10,	15,	21,	28.
Arith. Progres.	1,	3,	5,	7,	9,	11,	13.
Square Numbers	1,	4,	9,	16,	25,	36,	49.
Arith. Progres.	1,	4,	7,	10,	13,	16,	19.
Pentagonal Nos.	1,	5,	12,	22,	35,	51,	70.
Arith. Progres.	1,	5,	9,	13,	17,	21,	25.
Hexagonal Nos.	1,	6,	15,	28,	45,	66,	91.

The *Side* of a Polygonal number is the number of points in each side of the Polygonal figure when the points in the number are ranged in that form. And this is also the same as the number of terms of the arithmeticals that are added together in composing the Polygonal number; or, in short, it is the number of the term from the beginning. So, in the 2d or squares,



the side of the first (1) is 1, that of the second (4) is 2, that of the third (9) is 3, that of the fourth (16) is 4, and so on. And

The *Angles*, or Numbers of Angles, are the same as those of the figure from which the number takes its name. So the angles of the triangular numbers are 3, of the square ones 4, of the pentagonals 5, of the hexagonals 6, and so on. Hence, the angles are 2 more than the common difference of the arithmetical series from which any rank of Polygonals is formed: so the arithmetical series has for its common difference the number 1 or 2 or 3 &c as follows, viz, 1 in the triangles, 2 in the squares, 3 in the pentagons, &c; and, in general, if a be the number of angles in the Polygon, then $a - 2$ is $= d$ the common difference of the arithmetical series, or $d + 2 = a$ the number of angles.

PROB. 1. *To find any Polygonal Number proposed;* having given its side n and angles a. The Polygonal number being evidently the sum of the arithmetical progression whose number of terms is n and common difference $a - 2$, and the sum of an arithmetical progression being equal to half the product of the extremes by the number of terms, the extremes being 1 and $1 + d \cdot \overline{n-1} = 1 + \overline{a-2} \cdot \overline{n-1}$; therefore that number, or this sum, will be

$$\frac{n^2.d - n.\overline{d-2}}{2} \text{ or } \frac{n^2.\overline{a-2} - n.\overline{a-4}}{2},$$ where

d is the common difference of the arithmeticals that form the Polygonal number, and is always 2 less than the number of angles a.

Hence, for the several sorts of Polygons, any particular number whose side is n, will be found from either of these two formulæ, by using for d its values 1, 2, 3, 4, &c; which gives these following formulæ for the Polygonal number in each sort, viz, the

Triangular - $\frac{n^2 + n}{2}$,

Square - $\frac{2n^2 - 0n}{2} = n^2$,

Pentagonal - $\frac{3n^2 - n}{2}$,

Hexagonal - $\frac{4n^2 - 2n}{2}$,

Heptagonal - $\frac{5n^2 - 3n}{2}$,

&c.

PROB. 2. *To find the Sum of any Number of Polygonal Numbers of any order.*—Let the angles of the Polygon be

be a, or the common difference of the arithmeticals that form the Polygonals, d; and n the number of terms in the Polygonal ſeries, whoſe ſum is ſought: then is

$$\left(\frac{n^2-1}{6}d+\frac{n+1}{2}\right)n \text{ or } \left(\frac{n^2-1}{6}\cdot\overline{a-2}+\frac{n+1}{2}\right)n$$

the ſum of the n terms ſought.

Hence, ſubſtituting ſucceſſively the numbers 1, 2, 3, 4, &c, for d, there is obtained the following particular caſes, or formulæ, for the ſums of n terms of the ſeveral ranks of Polygonal numbers, viz, the ſum of the

Triangulars	-	$\frac{n^2+3n+2}{6}n$,
Squares	-	$\frac{2n^2+3n+1}{6}n$,
Pentagonals	-	$\frac{3n^2+3n+0}{6}n$,
Hexagonals	-	$\frac{4n^2+3n-1}{6}n$,
Heptagonals	-	$\frac{5n^2+3n-2}{6}n$,

&c

POLYGRAM, in Geometry, a figure conſiſting of many lines.

POLYHEDRON, or POLYEDRON, a body or ſolid contained by many rectilinear planes or ſides.

When the ſides of the Polyhedron are regular polygons, all ſimilar and equal, then the Polyhedron becomes a regular body, and may be inſcribed in a ſphere; that is, a ſphere may be deſcribed about it, ſo that its ſurface ſhall touch all the angles or corners of the ſolid. There are but five of theſe regular bodies, viz, the tetraedron, the hexaedron or cube, the octaedron, the dodecaedron, and the icoſaedron. See REGULAR *Body*, and each of thoſe five bodies ſeverally.

Gnomonical POLYHEDRON, is a ſtone with ſeveral faces, on which are projected various kinds of dials. Of this ſort, that in the Privy-garden, London, now gone to ruin, was eſteemed the fineſt in the world.

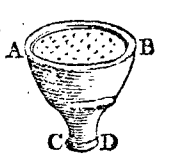
POLYHEDRON, in Optics. See POLYSCOPE.

POLYHEDROUS *Figure*, in Geometry, a ſolid contained under many ſides or planes. See POLYHEDRON.

POLYNOMIAL, in Algebra, a quantity of many names or terms, and is otherwiſe called a Multinomial. As $a+3b-2c+4d$, &c. See MULTINOMIAL.

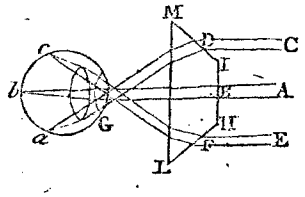
POLYOPTRUM, in Optics, a glaſs through which objects appear multiplied, but diminiſhed. The Polyoptrum differs both in ſtructure and phenomena from the common multiplying glaſſes called Polyhedra or Polyſcopes.

To conſtruct the Polyoptrum.—From a glaſs AB, plane on both ſides, and about 3 fingers thick, cut out ſpherical ſegments, ſcarce a 5th part of a digit in diameter.—If then the glaſs be removed to ſuch a diſtance from the eye, that you can take in all the cavities at one view, you will ſee the ſame object, as if through ſo many ſeveral concave glaſſes as there are cavities, and all exceeding ſmall.—Fit this, as an object-glaſs, in a tube ABCD, whoſe aperture AB is equal to the diameter of the glaſs, and the other CD is equal to that of an eye-glaſs, as for inſtance about a finger's breadth. The length of the tube AC is to be accommodated to the object-glaſs and eye-glaſs, by trial. In CD fit a convex eye-glaſs, or in its ſtead a meniſcus having the diſtance of its principal focus a little larger than the length of the tube; ſo that the point from which the rays diverge after refraction in the object-glaſs, may be in the focus. If then the eye be applied near the eye-glaſs, a ſingle object will be ſeen repeated as often as there are cavities in the object-glaſs, but ſtill diminiſhed.



POLYSCOPE, or POLYHEDRON, in Optics, is a multiplying glaſs, being a glaſs or lens which repreſents a ſingle object to the eye as if it were many. It conſiſts of ſeveral plane ſurfaces, diſpoſed into a convex form, through every one of which the object is ſeen.

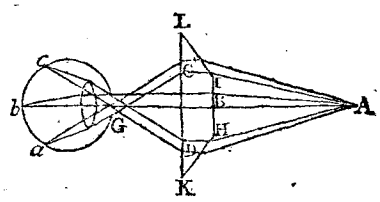
Phenomena of the Polyſcope.—1. If ſeveral rays, as EF, AB, CD, fall parallel on the ſurface of a Poly-



ſcope, they will continue parallel after refraction. If then the Polyſcope be ſuppoſed regular, LH, HI, IM will be as tangents cutting the ſpherical convex lens in F, B, and D; and conſequently, rays falling on the points of contact, interſect the axis. Wherefore, ſince the reſt are parallel to theſe, they will alſo mutually interſect each other in G.

Hence, if the eye be placed where parallel rays decuſſate, rays of the ſame object will be propagated to it ſtill parallel from the ſeveral ſides of the glaſs. Wherefore, ſince the cryſtalline humour, by its convexity, unites parallel rays, the rays will be united in as many different points of the retina, a, b, c, as the glaſs has ſides. Conſequently the eye, through a Polyſcope, ſees the object repeated as many times as there are ſides. And hence, ſince rays coming from very remote objects are parallel, a remote object is ſeen through a Polyſcope as often repeated as that has ſides.

2. If rays AB, AC, AD, coming from a radiant



point A, fall on ſeveral ſides of a regular Polyſcope;

after refraction they will decuſſate in G, and proceed on a little diverging.

Hence, if the eye be placed where the rays decuſſate after coming from the ſeveral planes, the rays will be propagated to it from the ſeveral planes a little diverging, or as if they proceeded from different points. But ſince the cryſtalline humour, by its convexity, collects rays from ſeveral points into the ſame point; the rays will be united in as many different points of the retina, *a*, *b*, *c*, as the glaſs has ſides; and conſequently the eye, being placed in the focus G, will ſee even a near object through the Polyſcope as often repeated as that has ſides.

Thus may the images of objects be multiplied in a camera obſcura, by placing a Polyſcope at its aperture, and adding a convex lens at a due diſtance from it. And it makes a very pleaſant appearance, if a priſm be applied ſo that the coloured rays of the ſun refracted from it be received on the Polyſcope: for by this means they will be thrown on a paper or wall near at hand in little lucid ſpecks, much exceeding the brightneſs of any precious ſtone; and in the focus of the Polyſcope, where the rays decuſſate (for in this experiment they are received on the convex ſide) will be a ſtar of ſurpriſing luſtre.

Farther, if images be painted in water-colours in the areolæ or little ſquares of a Polyſcope, and the glaſs be applied to the aperture of a camera obſcura; the ſun's rays, paſſing through it, will carry with them the images, and project them on the oppoſite wall.—This artifice bears a reſemblance to that other, by which an image on paper is projected on the camera; viz, by wetting the paper with oil, and ſtraining it tight in a frame; then applying it to the aperture of the camera obſcura, ſo that the rays of a candle may paſs through it upon the Polyſcope.

To make an Anamorphoſis, or Deformed Image, which ſhall appear regular and beautiful through a Polyſcope, or Multiplying Glaſs.—At one end of a horizontal table erect another perpendicularly, upon which a figure may be deſigned; and on the other end erect another, to ſerve as a fulcrum or ſupport, moveable on the horizontal one. To the fulcrum apply a plano-convex Polyſcope, conſiſting, for example, of 24 plane triangles; and let the Polyſcope be fitted in a draw-tube, of which that end towards the eye may have only a very ſmall aperture, and a little farther off than the focus. Remove the fulcrum from the other perpendicular table, till it be out of the diſtance of the focus; and the more ſo, as the image is to be greater. Before the little aperture place a lamp; and trace the luminous areolæ projected from the ſides of the Polyſcope, with a black lead pencil, on the vertical plane, or a paper applied upon it.

In the ſeveral areolæ, deſign the different parts of an image, in ſuch a manner as that, when joined together, they may make one whole, looking every now and then through the tube to guide and correct the colours, and to ſee that the ſeveral parts match and fit well together. As to the intermediate ſpace, it may be filled up with any figures or deſigns at pleaſure, contriving it ſo, as that to the naked eye the whole may exhibit ſome appearance very different from that intended to appear through the Polyſcope.

The eye, now looking through the ſmall aperture of the tube, will ſee the ſeveral parts and members diſperſed among the areolæ to exhibit one continued image, all the intermediate parts diſappearing. See ANAMORPHOSIS.

POLYSPASTON, in Mechanics, a machine ſo called by Vitruvius, conſiſting of an aſſemblage of ſeveral pullies, uſed for raiſing heavy weights.

PONTON, or PONTOON, a kind of flat-bottomed boat, whoſe carcaſs of wood is lined within and without with tin. Some nations line them on the outſide only, and that with plates of copper, which is better. Our Pontoons are 21 feet long, nearly 5 feet broad, and 2 feet 1½ inch deep within. They are carried along with an army upon carriages, to make temporary bridges, called Pontoon-bridges. See the next article.

PONTOON-*Bridge*, a bridge made of Pontoons ſlipped into the water, and moored by anchors and otherwiſe faſtened together by ropes, at ſmall diſtances from one another; then covered by beams of timber paſſing over them; upon which is laid a flooring of boards. By this means, whole armies of infantry, cavalry, and artillery are quickly paſſed over rivers.—For want of Pontoons, &c, bridges are ſometimes formed of empty powder caſks, or powder barrels, which ſupport the beams and flooring. Julius Cæſar and Aulus Gellius both mention Pontoons (pontones); but theirs were no more than a kind of ſquare flat veſſels, proper for carrying over horſe &c.

PONT-VOLANT, or *Flying-bridge*, is a kind of bridge uſed in ſieges, for ſurpriſing a poſt or outwork that has but narrow moats. It is made of two ſmall bridges laid over each other, and ſo contrived that, by means of cords and pullies placed along the ſides of the under bridge, the upper may be puſhed forwards, till it join the place where it is deſigned to be fixed. The whole length of both ought not to be above 5 fathoms, leſt it ſhould break with the weight of the men.

PORES, are the ſmall interſtices between the particles of matter which compoſe bodies; and are either empty, or filled with ſome inſenſible medium.

Condenſation and rarefaction are only performed by cloſing and opening the Pores. Alſo the tranſparency of bodies is ſuppoſed to ariſe from their Pores being directly oppoſite to one another. And the matter of inſenſible perſpiration is conveyed through the Pores of the cutis.

Mr. Boyle has a particular eſſay on the poroſity of bodies, in which he proves that the moſt ſolid bodies have ſome kind of Pores: and indeed if they had not, all bodies would be alike ſpecifically heavy.

Sir Iſaac Newton ſhews, that bodies are much more rare and porous than is commonly believed. Water, for example, is 19 times lighter and rarer than gold; and gold itſelf is ſo rare, as very readily, and without the leaſt oppoſition, to tranſmit magnetic effluvia, and eaſily to admit even quickſilver into its pores, and to let water paſs through it: for a concave ſphere of gold hath, when filled with water, and ſoldered up, upon preſſing it with a great force, ſuffered the water to ſqueeze through it, and ſtand all over its outſide, in multitudes of ſmall drops like dew, without burſting or cracking the gold. Whence it may be concluded, that

that gold has more pores than ſolid parts, and conſequently that water has above 40 times more Pores than parts. Hence it is that the magnetic effluvia paſſes freely through all cold bodies that are not magnetic; and that the rays of light paſs, in right lines, to the greateſt diſtances through pellucid bodies.

PORIME, *Porima*, in Geometry, a kind of eaſy lemma, or theorem ſo eaſily demonſtrated, that it is almoſt ſelf-evident: ſuch, for example, as that a chord is wholly within the circle.—Porime ſtands oppoſed to Aporime, which denotes a propoſition ſo difficult, as to be almoſt impoſſible to be demonſtrated, or effected. Such as the quadrature of the circle, &c.

PORISM, *Poriſma*, in Geometry, has by ſome been defined a general theorem, or canon, deduced from a geometrical locus, and ſerving for the ſolution of other general and difficult problems. Proclus derives the word from the Greek πορίζω, *I eſtabliſh*, and conclude from ſomething already done and demonſtrated: and accordingly he defines Poriſma a theorem drawn occaſionally from ſome other theorem already proved: in which ſenſe it agrees with what is otherwiſe called corollary.

Pappus ſays, a Poriſm is that in which ſomething was propoſed to be inveſtigated.

Others derive it from πόρος, *a paſſage*, and make it of the nature of a lemma, or a propoſition neceſſary for paſſing to another more important one.

But Dr. Simſon, rejecting the erroneous accounts that have been given of a Poriſm, defines it a propoſition, either in the form of a problem or a theorem, in which it is propoſed either to inveſtigate, or demonſtrate.

Euclid wrote three books of Poriſms, being a curious collection of various things relating to the analyſis of the more difficult and general problems. Thoſe books however are loſt; and nothing remains in the works of the ancient geometricians concerning this ſubject, beſides what Pappus has preſerved, in a very imperfect and obſcure ſtate, in his Mathematical Collections, viz, in the introduction to the 7th book.

Several attempts have been made to reſtore theſe writings in ſome degree, beſides that which Pappus has left upon the ſubject. Thus, Fermat has given a few propoſitions of this kind; which are to be found in the collection of his works, in folio, 1679, pa. 116. The like was done by Bullialdus, in his Exercitationes Geometricæ, 4to, 1657. Dr. Robert Simſon gave alſo a ſpecimen, in two propoſitions, in the Philoſ. Tranſ. vol. 32, pa. 330; and beſides left behind him a conſiderable treatiſe on the ſubject of Poriſms, which has been printed in an edition of his works, at the expence of the earl of Stanhope, in 4to, 1776.

The whole three books of Euclid were alſo reſtored by that ingenious mathematician Albert Girard, as appears by two notices that he gave, firſt in his Trigonometry, printed in French, at the Hague, in 1629, and alſo in his edition of the works of Stevinus, printed at Leyden in 1634, pa. 459; but whether his intention of publiſhing them was ever carried into execution, I have not been able to learn.

A learned paper on the ſubject of Poriſms, by the very ingenious Profeſſor Playfair, has juſt been inſerted in the 3d volume of the *Tranſactions* of the Royal Society of Edinburgh. As this paper contains a number of curious obſervations on the geometry of the Ancients in general, as well as forms a complete treatiſe as it were on Poriſm in particular, a pretty conſiderable abſtract of it cannot but be deemed in this place very uſeful and important.

"The reſtoration of the ancient books of geometry (ſays the learned profeſſor) would have been impoſſible, without the coincidence of two circumſtances, of which, though the one is purely accidental, the other is eſſentially connected with the nature of the mathematical ſciences. The firſt of theſe circumſtances is the preſervation of a ſhort abſtract of thoſe books, drawn up by Pappus Alexandrinus, together with a ſeries of ſuch lemmata, as he judged uſeful to facilitate the ſtudy of them. The ſecond is, the neceſſary connection that takes place among the objects of every mathematical work, which, by excluding whatever is arbitrary, makes it poſſible to determine the whole courſe of an inveſtigation, when only a few points in it are known. From the union of theſe circumſtances, mathematics has enjoyed an advantage of which no other branch of knowledge can partake; and while the critic or the hiſtorian has only been able to lament the fate of thoſe books of Livy and Tacitus which are loſt, the geometer has had the high ſatisfaction to behold the works of Euclid and Apollonius reviving under his hands.

"The firſt reſtorers of the ancient books were not, however, aware of the full extent of the work which they had undertaken. They thought it ſufficient to demonſtrate the propoſitions, which they knew from Pappus, to have been contained in thoſe books; but they did not follow the antient method of inveſtigation, and few of them appear to have had any idea of the elegant and ſimple analyſis by which theſe propoſitions were originally diſcovered, and by which the Greek Geometry was peculiarly diſtinguiſhed.

"Among theſe few, Fermat and Halley are to be particularly remarked. The former, one of the greateſt mathematicians of the laſt age, and a man in all reſpects of ſuperior abilities, had very juſt notions of the geometrical analyſis, and appears often abundantly ſkilful in the uſe of it; yet in his reſtoration of the Loci Plani, it is remarkable, that in the moſt difficult propoſitions, he lays aſide the analytical method, and contents himſelf with giving the ſynthetical demonſtration. The latter, among the great number and variety of his literary occupations, found time for a moſt attentive ſtudy of the ancient mathematicians, and was an inſtance of, what experience ſhews to be much rarer than might be expected, a man equally well acquainted with the ancient and the modern geometry, and equally diſpoſed to do juſtice to the merit of both. He reſtored the books of Apollonius, on the problem De Sectione Spatii, according to the true principles of the ancient analyſis.

"Theſe books, however, are but ſhort, ſo that the firſt reſtoration of conſiderable extent that can be reckoned complete, is that of the Loci Plani by Dr. Simſon, publiſhed in 1749, which, if it differs at all from the work it is intended to replace, ſeems to do ſo only by its greater excellence. This much at leaſt is certain, that the method of the ancient geometers does not appear to greater advantage in the moſt entire of their writings,

writings, than in the reſtoration above mentioned; and that Dr. Simſon has often ſacrificed the elegance to which his own analyſis would have led, in order to tread more exactly in what the lemmata of Pappus pointed out to him, as the track which Apollonius had purſued.

"There was another ſubject, that of Poriſms, the moſt intricate and enigmatical of any thing in the ancient geometry, which was ſtill reſerved to exerciſe the genius of Dr Simſon, and to call forth that enthuſiaſtic admiration of antiquity, and that unwearied perſeverance in reſearch, for which he was ſo peculiarly diſtinguiſhed. A treatiſe in three books, which Euclid had compoſed on Poriſms, was loſt, and all that remained concerning them was an abſtract of that treatiſe, inſerted by Pappus Alexandrinus in his Mathematical Collections, in which, had it been entire, the geometers of later times would doubtleſs have found wherewithal to conſole themſelves for the loſs of the original work. But unfortunately it has ſuffered ſo much from the injuries of time, that all which we can immediately learn from it is, that the Ancients put a high value on the propoſitions which they called Poriſms, and regarded them as a very important part of their analyſis. The Poriſms of Euclid are ſaid to be, "Collectio artificioſiſſima multarum rerum quæ ſpectant ad analyſin difficiliorum et generalium problematum." The curioſity, however, which is excited by this encomium is quickly diſappointed; for when Pappus proceeds to explain what a Poriſm is, he lays down two definitions of it, one of which is rejected by him as imperfect, while the other, which is ſtated as correct, is too vague and indefinite to convey any uſeful information.

"Theſe defects might nevertheleſs have been ſupplied, if the enumeration which he next gives of Euclid's Propoſitions had been entire; but on account of the extreme brevity of his enunciations, and their reference to a diagram which is loſt, and for the conſtructing of which no directions are given, they are all, except one, perfectly unintelligible. For theſe reaſons, the fragment in queſtion is ſo obſcure, that even to the learning and penetration of Dr. Halley, it ſeemed impoſſible that it could ever be explained; and he therefore concluded, after giving the Greek text with all poſſible correctneſs, and adding the Latin tranſlation, "Hactenus Poriſmatum deſcriptio nec mihi intellecta, "nec lectori profutura. Neque aliter fieri potuit, tam "ob defectum ſchematis cujus ſit mentio, quam ob "omiſſa quædam et tranſpoſita, vel aliter vitiata in propoſitionis generalis expoſitione, unde quid ſibi velit "Pappus haud mihi datum eſt conjicere. His adde "dictionis modum nimis contractum, ac in re difficili, "qualis hæc eſt, minime uſurpandum."

"It is true, however, that before this time, Fermat had attempted to explain the nature of Poriſms, and not altogether without ſucceſs. Guiding his conjectures by the definition which Pappus cenſures as imperfect, becauſe it defined Poriſms only "ab accidente," viz. "Poriſma eſt quod deficit hypotheſi a Theoremate Lo"cali," he formed to himſelf a tolerably juſt notion of theſe propoſitions, and illuſtrated his general deſcription by examples that are in effect Poriſms. But he was able to proceed no farther; and he neither proved, that his notion of a Poriſm was the ſame with Euclid's, nor attempted to reſtore, or explain any one of Euclid's propoſitions; much leſs did he ſuppoſe, that they were to be inveſtigated by an analyſis peculiar to themſelves. And ſo imperfect indeed was this attempt, that the complete reſtoration of the Poriſms was neceſſary to prove, that Fermat had even approximated to the truth.

"All this did not, however, deter Dr. Simſon from turning his thoughts to the ſame ſubject, which he appears to have done very early, and long before the publication of the Loci Plani in 1749.

"The account he gives of his progreſs, and of the obſtacles he encountered, will be always intereſting to mathematicians. "Poſtquam vero apud Pappum legeram, Poriſmata Euclidis collectionem fuiſſe artificioſiſſimam multarum rerum, quæ ſpectant ad analyſin "difficiliorum et generalium problematum, magno "deſiderio tenebar, aliquid de iis cognoſcendi; quare "ſæpius et multis variiſque viis tum Pappi propoſitionem generalem, mancam et imperfectam, tum primum lib. i.

"Poriſma, quod ſolum ex omnibus in tribus libris "integrum adhuc manet, intelligere et reſtituere "conabar; fruſtra tamen, nihil enim proficiebam. "Cumque cogitationes de hac re multum mihi temporis conſumpſerint, atque moleſtæ admodum evaſerint, "firmiter animum induxi hæc nunquam in poſterum "inveſtigare; præſertim cum optimus geometra Halleius ſpem omnem de iis intelligendis abjeciſſet. Unde quoties menti occurrebant, toties eas arcebam. "Poſtea tamen accidit, ut improvidum et propoſiti immemorem invaſerint, meque detinuerint donec tandem lux quædam effulſerit, quæ ſpem mihi faciebat "inveniendi ſaltem Pappi propoſitionem generalem, "quam quidem multa inveſtigatione tandem reſtitui. "Hæc autem paulo poſt una cum Poriſmate primo "lib. i. impreſſa eſt inter Tranſactiones Phil. anni 1723, "num. 177."

"The propoſitions mentioned, as inſerted in the Philoſophical Tranſactions for 1723, are all that Dr. Simſon publiſhed on the ſubject of Poriſms during his life, though he continued his inveſtigations concerning them, and ſucceeded in reſtoring a great number of Euclid's propoſitions, together with their analyſis. The propoſitions thus reſtored form a part of that valuable edition of the poſthumous works of this geometer which the mathematical world owes to the munificence of the late earl Stanhope.

"The ſubject of Poriſms is not, however, exhauſted, nor is it yet placed in ſo clear a light as to need no farther illuſtration. It yet remains to enquire into the probable origin of theſe propoſitions, that is to ſay, into the ſteps by which the ancient geometers appear to have been led to the diſcovery of them.

"It remains alſo to point out the relations in which they ſtand to the other claſſes of geometrical truths; to conſider the ſpecies of analyſis, whether geometrical or algebraical, that belongs to them; and, if poſſible, to aſſign the reaſon why they have ſo long eſcaped the notice of modern mathematicians. It is to theſe points that the following obſervations are chiefly directed.

"I begin with deſcribing the ſteps that appear to have led the ancient geometers to the diſcovery of Poriſms; and muſt here ſupply the want of expreſs teſti-

mony

mony by probable reaſonings, ſuch as are neceſſary, whenever we would trace remote diſcoveries to their ſources, and which have more weight in mathematics than in any other of the ſciences.

"It cannot be doubted, that it has been the ſolution of problems, which, in all ſtates of the mathematical ſciences, has led to the diſcovery of moſt geometrical truths. The firſt mathematical enquiries, in particular, muſt have occurred in the form of queſtions, where ſomething was given, and ſomething required to be done; and by the reaſonings neceſſary to anſwer theſe queſtions, or to diſcover the relation between the things that were given, and thoſe that were to be found, many truths were ſuggeſted, which came afterwards to be the ſubjects of ſeparate demonſtration. The number of theſe was the greater, that the ancient geometers always undertook the ſolution of problems with a ſcrupulous and minute attention, which would ſcarcely ſuffer any of the collateral truths to eſcape their obſervation. We know from the examples which they have left us, that they never conſidered a problem as reſolved, till they had diſtinguiſhed all its varieties, and evolved ſeparately every different caſe that could occur, carefully remarking whatever change might ariſe in the conſtruction, from any change that was ſuppoſed to take place among the magnitudes which were given.

"Now as this cautious method of proceeding was not better calculated to avoid error, than to lay hold of every truth that was connected with the main object of enquiry, theſe geometers ſoon obſerved, that there were many problems which, in certain circumſtances, would admit of no ſolution whatever, and that the general conſtruction by which they were reſolved would fail, in conſequence of a particular relation being ſuppoſed among the quantities which were given.

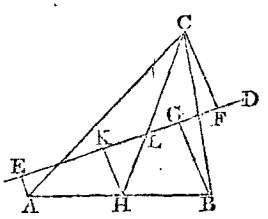
"Such problems were then ſaid to become impoſſible; and it was readily perceived, that this always happened, when one of the conditions preſcribed was inconſiſtent with the reſt, ſo that the ſuppoſition of their being united in the ſame ſubject, involved a contradiction. Thus, when it was required to divide a given line, ſo that the rectangle under its ſegment, ſhould be equal to a given ſpace, it was evident, that if this ſpace was greater than the ſquare of half the given line, the thing required could not poſſibly be done; the two conditions, the one defining the magnitude of the line, and the other that of the rectangle under its ſegments, being then inconſiſtent with one another. Hence an infinity of beautiful propoſitions concerning the maxima and the minima of quantities, or the limits of the poſſible relations which quantities may ſtand in to one another.

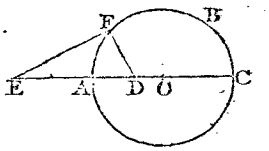
"Such caſes as theſe would occur even in the ſolution of the ſimpleſt problems; but when geometers proceeded to the analyſis of ſuch as were more complicated, they muſt have remarked, that their conſtructions would ſometimes fail, for a reaſon directly contrary to that which has now been aſſigned. Inſtances would be found where the lines that, by their interſection, were to determine the thing ſought, inſtead of interſecting one another, as they did in general, or of not meeting at all, as in the above-mentioned caſe of impoſſibility, would coincide with one another entirely, and leave the queſtion of conſequence unreſolved. But though this circumſtance muſt have created conſiderable embarraſſment to the geometers who firſt obſerved it, as being perhaps the only inſtance in which the language of their own ſcience had yet appeared to them ambiguous or obſcure, it would not probably be long till they found out the true interpretation to be put on it. After a little reflexion, they would conclude, that ſince, in the general problem, the magnitude required was determined by the interſection of the two lines above mentioned, that is to ſay, by the points common to them both; ſo, in the caſe of their coincidence, as all their points were in common, every one of theſe points muſt afford a ſolution; which ſolutions therefore muſt be infinite in number; and alſo, though infinite in number, they muſt all be related to one another, and to the things given, by certain laws, which the poſition of the two coinciding lines muſt neceſſarily determine.

"On enquiring farther into the peculiarity in the ſtate of the data which had produced this unexpected reſult, it might likewiſe be remarked, that the whole proceeded from one of the conditions of the problem involving another, or neceſſarily including it; ſo that they both together made in fact but one, and did not leave a ſufficient number of independent conditions, to confine the problem to a ſingle ſolution, or to any determinate number of ſolutions. It was not difficult afterwards to perceive, that theſe caſes of problems formed very curious propoſitions, of an intermediate nature between problems and theorems, and that they admitted of being enunciated ſeparately, in a manner peculiarly elegant and conciſe. It was to ſuch propoſitions, ſo enunciated, that the ancient geometers gave the name of Poriſms.

"This deduction requires to be illuſtrated by examples." Mr. Playfair then gives ſeveral problems by way of illuſtration; one of which, which may here ſuffice to ſhew the method, is as follows:

"A triangle ABC being given, and alſo a point D, to draw through D a ſtraight line DG, ſuch, that, perpendiculars being drawn to it from the three angles of the triangle, viz, AE, BG, CF, the ſum of the two perpendiculars on the ſame ſide of DG, ſhall be equal to the remaining perpendicular: or, that AE and BG together, may be equal to CF.





"Suppoſe it done: Biſect AB in H, join CH, and draw HK perpendicular to DG.

"Becauſe AB is biſected in H, the two perpendiculars AE and BG are together double of HK; and as they are alſo equal to CF by hypotheſis, CF muſt be double of HK; and CL of LH. Now, GH is given in poſition, and magnitude; therefore the point L is given;

given; and the point D being alſo given, the line DL is given in poſition, which was to be found.

"The conſtruction was obvious. Biſect AB in H, join CH, and take HL equal to one third of CH; the ſtraight line which joins the points D and L is the line required.

"Now, it is plain, that while the triangle ABC remains the ſame, the point L alſo remains the ſame, wherever the point D may be. The point D may therefore coincide with L; and when this happens, the poſition of the line to be drawn is left undetermined; that is to ſay, any line whatever drawn through L will ſatisfy the conditions of the problem. Here therefore we have another indefinite caſe of a problem, and of conſequence another Poriſm, which may be thus enunciated: "A triangle being given in poſition, a point in it may be found, ſuch, that any ſtraight line whatever being drawn through that point, the perpendiculars drawn to this ſtraight line from the two angles of the triangle which are on one ſide of it, will be together equal to the perpendicular that is drawn to the ſame line from the angle on the other ſide of it.

"This Poriſm may be made much more general; for if, inſtead of the angles of a triangle, we ſuppoſe ever ſo many points to be given in a plane, a point may be found ſuch, that any ſtraight line being drawn through it, the ſum of all the perpendiculars that fall on that line from the given points on one ſide of it, is equal to the ſum of the perpendiculars that fall on it from all the points on the other ſide of it.

"Or ſtill more generally, any number of points being given not in the ſame plane, a point may be found, through which if any plane be ſuppoſed to paſs, the ſum of all the perpendiculars which fall on that plane from the points on one ſide of it, is equal to the ſum of all the perpendiculars that fall on the ſame plane from the points on the other ſide of it. It is unneceſſary to obſerve, that the point to be found in theſe propoſitions, is no other than the centre of gravity of the given points; and that therefore we have here an example of a Poriſm very well known to the modern geometers, though not diſtinguiſhed by them from other theorems."

After ſome examples of other Poriſms, and remarks upon them, the author then adds,

"From this account of the origin of Poriſms, it follows, that a Poriſm may be defined, *A propoſition affirming the poſſibility of finding ſuch conditions as will render a certain problem indeterminate, or capable of innumerable ſolutions.*

"To this definition, the different characters which Pappus has given will apply without difficulty. The propoſitions deſcribed in it like thoſe which he mentions, are, ſtrictly ſpeaking, neither theorems nor problems, but of an intermediate nature between both; for they neither ſimply enunciate a truth to be demonſtrated, nor propoſe a queſtion to be ſolved: but are affirmations of a truth, in which the determination of an unknown quantity is involved. In as far therefore as they aſſert, that a certain problem may become indeterminate, they are of the nature of theorems; and in as far as they ſeek to diſcover the conditions by which that is brought about, they are of the nature of problems.

"In the preceding definition alſo, and the inſtances from which it is deduced, we may trace that imperfect deſcription of Poriſms which Pappus aſcribes to the later geometers, viz, "Poriſma eſt quod deficit hypotheſi a theoremate locali." Now, to underſtand this, it muſt be obſerved, that if we take the converſe of one of the propoſitions called *Loci*, and make the conſtruction of the figure a part of the hypotheſis, we have what was called by the Ancients a Local Theorem. And again, if, in enunciating this theorem, that part of the hypotheſis which contains the conſtruction be ſuppreſſed, the propoſition ariſing from thence will be a Poriſm; for it will enunciate a truth, and will alſo require, to the full underſtanding and inveſtigation of that truth, that ſomething ſhould be found, viz, the circumſtance in the conſtruction, ſuppoſed to be omitted.

"Thus when we ſay; If from two given points E and D (2d fig. above), two lines EF and FD are inflected to a third point F, ſo as to be to one another in a given ratio, the point F is in the circumference of a circle given in poſition: we have a *Locus*.

"But when converſely it is ſaid; If a circle ABC, of which the centre is O, be given in poſition, as alſo a point E, and if D be taken in the line EO, ſo that the rectangle EO OD be equal to the ſquare of AO, the ſemidiameter of the circle; and if from E and D, the lines EF and DF be inflected to any point whatever in the circumference ABC; the ratio of EF to DF will be a given ratio, and the ſame with that of EA to AD: we have a local theorem.

"And, laſtly, when it is ſaid; If a circle ABC be given in poſition, and alſo a point E, a point D may be found, ſuch, that if the two lines EF and FD be inflected from E and D to any point whatever F, in the circumference, theſe lines ſhall have a given ratio to one another: the propoſition becomes a Poriſm.

"Here it is evident, that the local theorem is changed into a Poriſm, by leaving out what relates to the determination of the point D, and of the given ratio. But though all propoſitions formed in this way, from the converſion of *Loci*, be Poriſms, yet all Poriſms are not formed from the converſion of *Loci*. The firſt and ſecond of the preceding, for inſtance, cannot by converſion be changed into *Loci*; and therefore the definition which deſcribes all Poriſms as being ſo convertible, is not ſufficiently comprehenſive. Fermat's idea of Poriſms, as has been already obſerved, was founded wholly on this definition, and therefore could not fail to be imperfect.

"It appears, therefore, that the definition of Poriſms given above agrees with Pappus's idea of theſe propoſitions, as far at leaſt as can be collected from the imperfect fragments which contain his general deſcription of them. It agrees alſo with Dr. Simſon's definition, which is this: "Poriſma eſt propoſitio in qua proponitur demonſtrare rem aliquam, vel plures datas eſſe, cui, vel quibus, ut et cuilibet ex rebus innumeris, non quidem datis, ſed quæ ad ea quæ data ſunt eandem habent relationem, convenire oſtendendum eſt affectionem quandam communem in propoſitione deſcriptam.

"It cannot be denied, that there is a conſiderable degree of obſcurity in this definition; notwithſtanding of which it is certain, that every propoſition to which it applies

applies muſt contain a *problematical* part, viz "in qua proponitur demonſtrare rem aliquam, vel plures datas eſſe," and alſo a *theoretical* part, which contains the property, or *communis affectio*, affirmed of certain things which have been previouſly deſcribed.

"It is alſo evident, that the ſubject of every ſuch propoſition, is the relation between magnitudes of three different kinds; determinate magnitudes which are given; determinate magnitudes which are to be found; and indeterminate magnitudes which, though unlimited in number, are connected with the others by ſome common property. Now, theſe are exactly the conditions contained in the definitions that have been given here.

"To confirm the truth of this theory of the origin of Poriſms, or at leaſt the juſtneſs of the notions founded on it, I muſt add a quotation from an Eſſay on the ſame ſubject, by a member of this ſociety, the extent and correctneſs of whoſe views make every coincidence with his opinions peculiarly flattering. In a paper read ſeveral years ago before the Philoſophical Society, Profeſſor Dugald Stewart defined a Poriſm to be "A propoſition affirming the poſſibility of finding one or more of the conditions of an indeterminate theorem." Where, by an indeterminate theorem, as he had previouſly explained it, is meant one which expreſſes a relation between certain quantities that are indeterminate, both in magnitude and in number. The near agreement of this with the definition and explanations which have been given above, is too obvious to require to be pointed out; and I have only to obſerve, that it was not long after the publication of Simſon's poſthumous works, when, being both of us occupied in ſpeculations concerning Poriſms, we were led ſeparately to the concluſions which I have now ſtated.

"In an enquiry into the origin of Poriſms, the etymology of the term ought not to be forgotten. The queſtion indeed is not about the derivation of the word Πορισμα, for concerning that there is no doubt; but about the reaſon why this term was applied to the claſs of propoſitions above deſcribed. Two opinions may be formed on this ſubject, and each of them with conſiderable probability: 1*mo*. One of the ſignifications of πορίζω, is *to acquire or obtain*; and hence Πορισμα, *the thing obtained or gained*.

"Accordingly, Scapula ſays, *Eſt vox a geometris deſumpta qui theorema aliquid ex demonſtrativo ſyllogiſmo neceſſario ſequens inferentes, illud quaſi lucrari dicuntur, quod non ex profeſſo quidem theorematis hujus inſtituta ſit demonſtratio, ſed tamen ex demonſtratis recte ſequatur*. In this ſenſe Euclid uſes the word in his Elements of Geometry, where he calls the corollaries of his propoſition, *Poriſmata*. This circumſtance creates a preſumption, that when the word was applied to a particular claſs of propoſitions, it was meant, in both caſes, to convey nearly the ſame idea; as it is not at all probable, that ſo correct a writer as Euclid, and ſo ſcrupulous in his uſe of words, ſhould employ the ſame term to expreſs two ideas which are perfectly different. May we not therefore conjecture, that theſe propoſitions got the name of Poriſms, entirely with a reference to their origin. According to the idea explained above, they would in general occur to mathematicians when engaged in the ſolution of the more difficult problems, and would ariſe from thoſe particular caſes, where one of the conditions of the data involved in it ſome one of the reſt. Thus a particular kind of theorem would be obtained, following as a corollary from the ſolution of the problem: and to this theorem the term Πορισμα might be very properly applied, ſince, in the words of Scapula, already quoted, *Non ex profeſſo theorematis hujus inſtituta ſit demonſtratio, ſed tamen ex demonſtratis recte ſequatur*.

"2do. But though this interpretation agrees ſo well with the ſuppoſed origin of Poriſms, it is not free from difficulty. The verb πορίζω has another ſignification, *to find out, to diſcover, to deviſe*; and is uſed in this ſenſe by Pappus, when he ſays that the propoſitions called Poriſms, afford great delight, τοις δυναμενοις ορειν και πορίζμα, *to thoſe who are able to underſtand and inveſtigate*. Hence comes πορισμος, *the act of finding out or diſcovering*, and from πορισμος, in this ſenſe, the ſame author evidently conſiders Πορισμα as being derived. His words are, Εφασαν δε (οι αρχαιοι) Πορισμα ειναιτο προτεινομενον εις Πορισμον αυτω προτεινομενω, *the Ancients ſaid, that a Poriſm is ſomething propoſed for the* finding out, *or* diſcovering *of the very thing propoſed*. It ſeems ſingular, however, that Poriſms ſhould have taken their name from a circumſtance common to them with ſo many other geometrical truths; and if this was really the caſe, it muſt have been on account of the enigmatical form of their enunciations, which required, that in the analyſis of theſe propoſitions, a ſort of double diſcovery ſhould be made, not only of the Truth, but alſo of the Meaning *of the very thing which was propoſed*. They may therefore have been called *Poriſmata*, or *inveſtigations*, by way of eminence.

"We might next proceed to conſider the particular Poriſms which Dr. Simſon has reſtored, and to ſhew, that every one of them is the indeterminate caſe of ſome problem. But of this it is ſo eaſy for any one, who has attended to the preceding remarks, to ſatisfy himſelf, by barely examining the enunciations of thoſe propoſitions, that the detail unto which it would lead ſeems to be unneceſſary. I ſhall therefore go on to make ſome obſervations on that kind of analyſis which is particularly adapted to the inveſtigation of Poriſms.

"If the idea which we have given of theſe propoſitions be juſt, it follows, that they are always to be diſcovered by conſidering the caſes in which the conſtruction of a problem fails in conſequence of the lines which, by their interſection, or the points which, by their poſition, were to determine the magnitude required, happening to coincide with one another—a Poriſm may therefore be deduced from the problem it belongs to, in the ſame manner that the propoſitions concerning the *maxima* and *minima* of quantities are deduced from the problems of which they form the limitations; and ſuch no doubt is the moſt natural and moſt obvious analyſis of which this claſs of propoſitions will admit.

"It is not, however, the only one that they will admit of; and there are good reaſons for wiſhing to be provided with another, by means of which, a Poriſm that is any how ſuſpected to exiſt, may be found out, independently of the general ſolution of the problem to which it belongs. Of theſe reaſons, one is, that the Poriſm may perhaps admit of being inveſtigated more eaſily than the general problem admits of being reſolved;

and another is; that the former, in almoſt every caſe, helps to diſcover the ſimpleſt and moſt elegant ſolution that can be given of the latter.

" It is deſirable to have a method of inveſtigating Poriſms, which does not require, that we ſhould have previouſly reſolved the problems they are connected with, and which may always ſerve to determine, whether to any given problem there be attached a Poriſm, or not. Dr. Simſon's Analyſis may be conſidered as anſwering to this deſcription; for as that geometer did not regard theſe propoſitions at all in the light that is done here, nor in relation to their origin, an independent analyſis of this kind, was the only one that could occur to him; and he has accordingly given one which is extremely ingenious, and by no means eaſy to be invented, but which he uſes with great ſkilfulneſs and dexterity throughout the whole of his Reſtoration.

" It is not eaſy to aſcertain whether this be the preciſe method uſed by the Ancients. Dr. Simſon had here nothing to direct him but his genius, and has the full merit of the firſt inventor. It ſeems probable, however, that there is at leaſt a great affinity between the methods, ſince the *lemmata* given by Pappus as neceſſary to Euclid's demonſtrations, are ſubſervient alſo to thoſe of our modern geometer.

" It is, as we have ſeen, a general principle that a problem is converted into a Poriſm, when one, or when two, of the conditions of it, neceſſarily involve in them ſome one of the reſt. Suppoſe then that two of the conditions are exactly in that ſtate which determines the third; then, while they remain fixed or given, ſhould that third one be ſuppoſed to vary, or differ, ever ſo little, from the ſtate required by the other two, a contradiction will enſue. Therefore if, in the hypotheſis of a problem, the conditions be ſo related to one another as to render it indeterminate, a Poriſm is produced; but if, of the conditions thus related to one another, ſome one be ſuppoſed to vary, while the others continue the ſame, an abſurdity follows, and the problem becomes impoſſible. *Wherever therefore any problem admits both of an indeterminate, and an impoſſible caſe, it is certain, that theſe caſes are nearly related to one another, and that ſome of the conditions by which they are produced, are common to both.*

" It is ſuppoſed above, that *two* of the conditions of a problem involve in them a third, and wherever that happens, the concluſion which has been deduced will invariably take place.

" But a Poriſm may ſometimes be ſo ſimple, as to ariſe from the mere coincidence of *one* condition of a problem with another, though in no caſe whatever, any inconſiſtency can take place between them. Thus, in the ſecond of the foregoing propoſitions, the coincidence of the point given in the problem with another point, viz. the centre of gravity of the given triangle, renders the problem indeterminate; but as there is no relation of diſtance, or poſition, between theſe points, that may not exiſt, ſo the problem has no impoſſible caſe belonging to it. There are, however, comparatively but few Poriſms ſo ſimple in their origin as this, or that ariſe from problems in which the conditions are ſo little complicated; for it uſually happens, that a problem which can become indefinite, may alſo become impoſſible; and if ſo, the connection between theſe caſes, which has been already explained, never fails to take place.

" Another ſpecies of impoſſibility may frequently ariſe from the poriſmatic caſe of a problem, which will very much affect the application of geometry to aſtronomy, or any of the ſciences of experiment or obſervation. For when a problem is to be reſolved by help of data furniſhed by experiment or obſervation, the firſt thing to be conſidered is, whether the data ſo obtained, be ſufficient for determining the thing ſought, and in this a very erroneous judgment may be formed, if we reſt ſatisfied with a general view of the caſe. For though the problem may in general be reſolved from the data that we are provided with, yet theſe data may be ſo related to one another in the caſe before us, that the problem will become indeterminate, and inſtead of one ſolution, will admit of an infinite number.

" Suppoſe, for inſtance, that it were required to determine the poſition of a point F from knowing that it was ſituated in the circumference of a given circle ABC, and alſo from knowing the ratio of its diſtances from two given points E and D; it is certain that in general theſe data would be ſufficient for determining the ſituation of F. But nevertheleſs, if E and D ſhould be ſo ſituated, that they were in the ſame ſtraight line with the centre of the given circle; and if the rectangle under their diſtances from that centre, were alſo equal to the ſquare of the radius of the circle, then, the poſition of F could not be determined.

" This particular inſtance may not indeed occur in any of the practical applications of geometry; but there is one of the ſame kind which has actually occurred in aſtronomy: And as the hiſtory of it is not a little ſingular, affording beſides an excellent illuſtration of the nature of Poriſms, I hope to be excuſed for entering into the following detail concerning it.

" Sir Iſaac Newton having demonſtrated, that the trajectory of a comet is a parabola, reduced the actual determination of the orbit of any particular comet to the ſolution of a geometrical problem, depending on the properties of the parabola, but of ſuch conſiderable difficulty, that it is neceſſary to take the aſſiſtance of a more elementary problem, in order to find, at leaſt nearly, the diſtance of the comet from the earth, at the times when it was obſerved. The expedient for this purpoſe, ſuggeſted by Newton himſelf, was to conſider a ſmall part of the comet's path as rectilineal, and deſcribed with an uniform motion, ſo that four obſervations of the comet being made at moderate intervals of time from one another, four ſtraight lines would be determined, viz, the four lines joining the places of the earth and the comet, at the times of obſervation, acroſs which if a ſtraight line were drawn, ſo as to be cut by them in three parts, in the ſame ratios with the intervals of time abovementioned; the line ſo drawn would nearly repreſent the comet's path, and by its interſection with the given lines, would determine, at leaſt nearly, the diſtances of the comet from the earth at the time of obſervation.

" The geometrical problem here employed, of drawing a line to be divided by four other lines given in poſition, into parts having given ratios to one another, had been already reſolved by Dr. Wallis and Sir Chriſtopher

topher Wren, and to their ſolutions Sir Iſaac Newton added three others of his own, in different parts of his works. Yet none of all theſe geometers obſerved that peculiarity in the problem which rendered it inapplicable to aſtronomy. This was firſt done by M. Boſcovich, but not till after many trials, when, on its application to the motion of comets, it had never led to any ſatisfactory reſult. The errors it produced in ſome inſtances were ſo conſiderable, that Zanotti, ſeeking to determine by it the orbit of the comet of 1739, found, that his conſtruction threw the comet on the ſide of the ſun oppoſite to that on which he had actually obſerved it. This gave occaſion to Boſcovich, ſome years afterwards, to examine the different caſes of the problem, and to remark that, in one of them, it became indeterminate, and that, by a curious coincidence, this happened in the only caſe which could be ſuppoſed applicable to the aſtronomical problem abovementioned; in other words, he found, that in the ſtate of the data, which muſt there always take place, innumerable lines might be drawn, that would be all cut in the ſame ratio, by the four lines given in poſition. This he demonſtrated in a diſſertation publiſhed at Rome in 1749, and ſince that time in the third volume of his *Opuſcula*. A demonſtration of it, by the ſame author, is alſo inſerted at the end of Caſtillon's Commentary on the *Arithmetica Univerſalis*, where it is deduced from a conſtruction of the general problem, given by Mr. Thomas Simpſon, at the end of his Elements of Geometry. The propoſition, in Boſcovich's words, is this: Problema quo quæritur recta linea quæ quatuor rectas poſitione datas ita ſecet, ut tria ejus ſegmenta ſint invicem in ratione data, evadit aliquando indeterminatum, ita ut per quodvis punctum cujuſvis ex iis quatuor rectis duci poſſit recta linea, quæ ei conditioni faciat ſatis.

"It is needleſs, I believe, to remark, that the propoſition thus enunciated is a Poriſm, and that it was diſcovered by Boſcovich, in the ſame way, in which I have ſuppoſed Poriſms to have been firſt diſcovered by the geometers of antiquity.

"A queſtion nearly connected with the origin of Poriſms ſtill remains to be ſolved, namely, from what cauſe has it ariſen that propoſitions which are in themſelves ſo important, and that actually occupied ſo conſiderable a place in the ancient geometry, have been ſo little remarked in the modern? It cannot indeed be ſaid, that propoſitions of this kind were wholly unknown to the Moderns before the reſtoration of what Euclid had written concerning them; for beſides M. Boſcovich's propoſition, of which ſo much has been already ſaid, the theorem which aſſerts, that in every ſyſtem of points there is a centre of gravity, has been ſhewn above to be a Poriſm; and we ſhall ſee hereafter, that many of the theorems in the higher geometry belong to the ſame claſs of propoſitions. We may add, that ſome of the elementary propoſitions of geometry want only the proper form of enunciation to be perfect Poriſms. It is not therefore ſtrictly true, that none of the propoſitions called Poriſms have been known to the Moderns; but it is certain, that they have not met, from them, with the attention they met with from the Ancients, and that they have not been diſtinguiſhed as a ſeparate claſs of propoſitions. The cauſe of this difference is undoubtedly to be ſought for in a compariſon of the methods employed for the ſolution of geometrical problems in ancient and modern times.

"In the ſolution of ſuch problems, the geometers of antiquity proceeded with the utmoſt caution, and were careful to remark every particular caſe, that is to ſay, every change in the conſtruction, which any change in the ſtate of the data could produce. The different conditions from which the ſolutions were derived, were ſuppoſed to vary one by one, while the others remained the ſame; and all their poſſible combinations being thus enumerated, a ſeparate ſolution was given, wherever any conſiderable change was obſerved to have taken place.

"This was ſo much the caſe, that the *Sectio Rationis*, a geometrical problem of no great difficulty, and one of which the ſolution would be diſpatched, according to the methods of the modern geometry, in a ſingle page, was made by Apollonius, the ſubject of a treatiſe conſiſting of two books. The firſt book has ſeven general diviſions, and twenty-four caſes; the ſecond, fourteen general diviſions, and ſeventy-three caſes, each of which caſes is ſeparately conſidered. Nothing, it is evident, that was any way connected with the problem, could eſcape a geometer, who proceeded with ſuch minuteneſs of inveſtigation.

"The ſame ſcrupulous exactneſs may be remarked in all the other mathematical reſearches of the Ancients; and the reaſon doubtleſs is, that the geometers of thoſe ages, however expert they were in the uſe of their analyſis, had not ſufficient experience in its powers, to truſt to the more general applications of it. That principle which we call the *law of continuity*, and which connects the whole ſyſtem of mathematical truths by a chain of inſenſible gradations, was ſcarcely known to them, and has been unfolded to us, only by a more extenſive knowledge of the mathematical ſciences, and by that moſt perfect mode of expreſſing the relations of quantity, which forms the language of algebra; and it is this principle alone which has taught us, that though in the ſolution of a problem, it may be impoſſible to conduct the inveſtigation without aſſuming the data in a *particular* ſtate, yet the reſult may be perfectly *general*, and will accommodate itſelf to every caſe with ſuch wonderful verſatility, as is ſcarcely credible to the moſt experienced mathematician, and ſuch as often forces him to ſtop, in the midſt of his calculus, and look back, with a mixture of diffidence and admiration, on the unforeſeen harmony of his concluſions. All this was unknown to the Ancients; and therefore they had no reſource, but to apply their analyſis ſeparately to each particular caſe, with that extreme caution which has juſt been deſcribed; and in doing ſo, they were likely to remark many peculiarities, which more extenſive views, and more expeditious methods of inveſtigation, might perhaps have induced them to overlook.

"To reſt ſatisfied, indeed, with too general reſults, and not to deſcend ſufficiently into particular details, may be conſidered as a vice that naturally ariſes out of the excellence of the modern analyſis. The effect which this has had, in concealing from us the claſs of propoſitions we are now conſidering, cannot be better illuſtrated than by the example of the Poriſm diſcovered by Boſcovich, in the manner related above. Though the problem from which that Poriſm is derived, was

reſolved by ſeveral mathematicians of the firſt eminence, among whom alſo was Sir Iſaac Newton, yet the Poriſm which, as it happens is the moſt important caſe of it, was not obſerved by any of them. This is the more remarkable, that Sir Iſaac Newton takes notice of the two moſt ſimple caſes, in which the problem obviouſly admits of innumerable ſolutions, viz, when the lines given in poſition are either all parallel, or all meeting in a point, and theſe two hypotheſes he therefore expreſsly excepts. Yet he did not remark, that there are other circumſtances which may render the ſolution of the problem indeterminate as well as theſe; ſo that the poriſmatic caſe conſidered above, eſcaped his obſervation; and if it eſcaped the obſervation of one who was accuſtomed to penetrate ſo far into matters infinitely more obſcure, it was becauſe he ſatisfied himſelf with a general conſtruction, without purſuing it into its particular caſes. Had the ſolution been conducted after the manner of Euclid or Apollonius, the Poriſm in queſtion muſt infallibly have been diſcovered."

PORISTIC *Method*, is that which determines when, by what means, and how many different ways, a problem may be reſolved.

PORTA (JOHN BAPTISTA), called alſo in Italy *Giovan Batiſta de la Porta*, of Naples, lived about the end of the 16th century, and was famous for his ſkill in philoſophy, mathematics, medicine, natural hiſtory, &c, as well as for his indefatigable endeavours to improve and propagate the knowledge of thoſe ſciences. With this view, he not only eſtabliſhed private ſchools for particular ſciences, but to the utmoſt of his power promoted public academies. He had no ſmall ſhare in eſtabliſhing the academy at *Gli Ozioni*, at Naples, and had one in his own houſe, called *de Secreti*, into which none were admitted members, but ſuch as had made ſome new diſcoveries in nature. He died at Piſa, in the kingdom of Naples, in the year 1615.

Porta gave the fulleſt proof of an extenſive genius, and wrote a great many works; the principal of which are as follow:

1. His *Natural Magic*; a book abounding with curious experiments; but containing nothing of magic, the common acceptation of the word, as he pretends to nothing above the power of nature.
2. *Elements of Curve Lines.*
3. *A Treatiſe of Diſtillation.*
4. *A Treatiſe of Arithmetic.*
5. *Concerning Secret Letter-writing.*
6. *Of Optical Refractions.*
7. *A Treatiſe of Fortification.*
8. *A Treatiſe of Phyſiognomy.*

Beſide ſome Plays and other pieces of leſs note.

PORTAIL, in Architecture, the face or frontiſpiece of a church, viewed on the ſide in which the great door is placed. It means alſo the great door or gate itſelf of a palace, caſtle, &c.

PORTAL, in Architecture, a term uſed for a little ſquare corner of a room, cut off from the reſt of the room by the wainſcot; frequent in the ancient buildings, but now diſuſed.

PORTAL is ſometimes alſo uſed for a little gate, portella; where there are two gates, a large and a ſmall one.

PORTAL is ſometimes alſo uſed for a kind of arch of joiner's work before a door.

PORTCULLICE, called alſo *Herſe*, and *Sarraſin*, in Fortification, an aſſemblage of ſeveral large pieces of wood laid or joined acroſs one another, like a harrow, and each pointed at the bottom with iron. Theſe were formerly uſed to be hung over the gateways of fortified places, to be ready to let down in caſe of a ſurprize, when the enemy ſhould come ſo quick, as not to allow time to ſhut the gates. But the orgues are now generally uſed, being found to anſwer the purpoſe better.

PORT-FIRE, in Gunnery, a paper tube, about 10 inches long, filled with a compoſition of meal-powder, ſulphur, and nitre, rammed moderately hard; uſed to fire guns and mortars, inſtead of match.

PORTICO, in Architecture, is a kind of gallery, raiſed upon arches, under which people walk for ſhelter.

POSITION, or *Site*, or *Situation*, in Phyſics, is an affection of place, expreſſing the manner of a body's being in it.

POSITION, in Architecture, denotes the ſituation of a building, with reſpect to the points of the horizon. The beſt it is thought is when the four ſides point directly to the four winds.

POSITION, in Aſtronomy, relates to the ſphere. The poſition of the ſphere is either right, parallel, or oblique; whence ariſe the inequality of days, the difference of ſeaſons, &c.

Circles of POSITION, are circles paſſing through the common interſections of the horizon and meridian, and through any degree of the ecliptic, or the centre of any ſtar, or other point in the heavens; uſed for finding out the poſition or ſituation of any ſtar. Theſe are uſually counted ſix in number, cutting the equator into twelve equal parts, which the aſtrologers call the celeſtial houſes.

POSITION, in Arithmetic, called alſo Falſe Poſition, or Suppoſition, or Rule of Falſe, is a rule ſo called, becauſe it conſiſts in calculating by falſe numbers ſuppoſed or taken at random, according to the proceſs deſcribed in any queſtion or problem propoſed, as if they were the true numbers, and then from the reſults, compared with that given in the queſtion, the true numbers are found. It is ſometimes alſo called Trial-and-Error, becauſe it proceeds by trials of falſe numbers, and thence finds out the true ones by a compariſon of the errors.

Poſition is either Single or Double.

Single POSITION is when only one ſuppoſition is employed in the calculation. And

Double POSITION is that in which two ſuppoſitions are employed.

To the rule of Poſition properly belong ſuch queſtions as cannot be reſolved from a direct proceſs by any of the other uſual rules in arithmetic, and in which the required numbers do not aſcend above the firſt power; ſuch, for example, as moſt of the queſtions uſually brought to exerciſe the reduction of ſimple equations in algebra. But it will not bring out true anſwers when the numbers ſought aſcend above the firſt power; for then the reſults are not proportional to the Poſitions,

or

or ſuppoſed numbers, as in the ſingle rule; nor yet the errors to the difference of the true number and each Poſition, as in the double rule. Yet in all ſuch caſes, it is a very good approximation, and in exponential equations, as well as in many other things, it ſucceeds better than perhaps any other method whatever.

Thoſe queſtions, in which the reſults are proportional to their ſuppoſitions, belong to Single Poſition: ſuch are thoſe which require the multiplication or diviſion of the number ſought by any number; or in which it is to be increaſed or diminiſhed by itſelf any number of times, or by any part or parts of it. But thoſe in which the reſults are not proportional to their poſitions, belong to the double rule: ſuch are thoſe, in which the numbers ſought, or their multiples or parts, are increaſed or diminiſhed by ſome given abſolute number, which is no known part of the number ſought.

To work by *the Single Rule of* POSITION. Suppoſe, take, or aſſume any number at pleaſure, for the number ſought, and proceed with it as if it were the true number, that is, perform the ſame operations with it as, in the queſtion, are deſcribed to be performed with the number required: then if the reſult of thoſe operations be the ſame with that mentioned or given in the queſtion, the ſuppoſed number is the ſame as the true one that was required; but if it be not, make this proportion, viz, as your reſult is to that in the queſtion, ſo is your ſuppoſed falſe number, to the true one required.

Example. Suppoſe that a perſon, after ſpending $\frac{1}{3}$ and $\frac{1}{4}$ of his money, has yet remaining 60l.; what ſum had he at firſt?

Suppoſe he had at firſt 120l.

Now $\frac{1}{3}$ of 120 is	40
and $\frac{1}{4}$ of it is	30
their ſum is	70
which taken from	120
leaves remaining	50, inſtead of 60.

Therefore as 50 : 60 :: 120 : 144 the ſum at firſt.

Proof.

$\frac{1}{3}$ of 144 is	48
$\frac{1}{4}$ of it is	36
their ſum	84
taken from	144
leaves juſt	60 as per queſt.

To work by the Double Rule of POSITION.

In this rule, make two different ſuppoſitions, or aſſumptions, and work or perform the operations with each, deſcribed in the queſtion, exactly as in the ſingle rule: and if neither of the ſuppoſed numbers ſolve the queſtion, that is, produce a reſult agreeing with that in the queſtion; then obſerve the errors, or how much each of the falſe reſults differs from the true one, and alſo whether they are too great or too little; marking them with + when too great, and with − when too little. Next multiply, croſſwiſe, each poſition by the error of the other; and if the errors be of the ſame affection, that is both +, or both −, ſubtract the one product from the other, as alſo the one error from the other, and divide the former of theſe two remainders by the latter, for the anſwer, or number ſought. But if the errors be unlike, that is, the one +, and the other −, add the two products together, and alſo the two errors together, and divide the former ſum by the latter, for the anſwer.

And in this rule it is particularly uſeful to remember this part of the rule, viz. to ſubtract when the errors are alike, both + or both −, but to add when unlike, or the one + and the other −.

Example. A ſon aſking his father how old he was, received this anſwer: Your age is now $\frac{1}{4}$ of mine; but 5 years ago your age was only $\frac{1}{5}$ of mine at that time. What then were their ages?

Firſt, ſuppoſe the ſon 15;

then 15 × 4 = 60 the father's;
alſo, 5 years ago the ſon was 10,
and the father's muſt be 55,
but ought to be 10 × 5 or 50,
therefore the error is 5+.

Again, ſuppoſe the ſon 22;

then 22 × 4 = 88 is the father's;
alſo 5 years ago the ſon was 17,
and the father's then 83,
but ought to be 17 × 5, or 85,
therefore the error is 2+.

And the errors, being unlike, muſt be added, their ſum being 7.

Then 15	22
2	5
30	110
	30

7) 140 (20 the ſon's age,
and conſequently 80 the father's.

This rule of Poſition, or trial-and-error, is a good general way of approximating to the roots of the higher equations, to which it may be applied even before the equation is reduced to a final or ſimple ſtate, by which it often ſaves much trouble in ſuch reductions. It is alſo eminently uſeful in reſolving exponential equations, and equations involving arcs, or ſines, &c, or logarithms, and in ſhort in any equations that are very intricate and difficult. And even in the extraction of the higher roots of common numbers, it may be very uſefully applied. As for inſtance, to extract the 3d or cubic root of the number 20.—Here it is evident that the root is greater than 2 and leſs than 3; making theſe two numbers therefore the ſuppoſitions, the proceſs will be thus:

1ſt ſup.	$2^3 = 8$	2d ſup.	$3^3 = 27$
given number	20	given number	20
1ſt error	12−	2d error	7+
	3		2
	12 36 } add		14
	7 14 }		

19) 50 (2·63 the firſt approximation.

Again,

Again, as it thus appears the cube root of 20 is near 2·6 or 2·7, make ſuppoſition of theſe two, and repeat the proceſs with them, thus:

1ſt ſup. $2{\cdot}6^3 = 17{\cdot}576$		2d ſup. $2{\cdot}7^3 = 19{\cdot}683$	
given number	20·	given number	20·
1ſt error	2·424—	2d error	0·317—
	2·7		2·6
	16968		1902
	4848		634
2·424	6·5448 } ſubtr.		·8242
·317	·8242 }		
2·107)	5·7206 (2·714 root ſought.		

The rule of Poſition paſſed from the Moors into Europe, by Spain and Italy, along with their algebra, or method of equations, which was probably derived from the former.

Position, in Geometry, reſpects the ſituation, bearing, or direction of one thing, with regard to another. And Euclid ſays, "Points, lines, and angles, which have and keep always one and the ſame place and ſituation, are ſaid to be given by Poſition or ſituation." Data, def. 4.

POSITIVE *Quantities*, in Algebra, ſuch as are of a real, affirmative, or additive nature; and which either have, or are ſuppoſed to have, the affirmative or poſitive ſign + before them; as a or $+a$, or bc, &c. It is uſed in contradiſtinction from negative quantities, which are defective or ſubductive ones, and marked by the ſign —; as $-a$, or $-ab$.

POSTERN, or *Sally-port*, in Fortification, a ſmall gate, uſually made in the angle of the flank of a baſtion, or in that of the curtain, or near the orillon, deſcending into the ditch; by which the garriſon can march in and out, unperceived by the enemy, either to relieve the works, or to make private ſallies, &c.—It means alſo any private or back door.

POSTICUM, in Architecture, the poſtern gate, or back-door of any fabric.

POSTULATE, a demand, petition, or a problem of ſo obvious a nature, as to need neither demonſtration, nor explication, to render it either more plain or certain. This definition will nearly agree alſo to an axiom, which is a ſelf-evident theorem, as a Poſtulate is a ſelf-evident problem.

Euclid lays down theſe three Poſtulates in his Elements; viz, 1ſt, That from one point to another a line can be drawn. 2d, That a right line can be produced out at pleaſure. 3d, That with any centre and radius a circle may be deſcribed.

As to axioms, he has a great number; as, That two things which are equal to one and the ſame thing, are equal to each other, &c.

POUND, a certain weight; which is of two kinds, viz, the pound troy, and the pound avoirdupois; the former conſiſting of 12 ounces troy, and the latter of 16 ounces avoirdupois.—The pound troy is to the pound avoirdupois as 5760 to 6999½, or nearly 576 to 700.

Pound alſo is an imaginary money uſed in accounting, in ſeveral countries. Thus, in England there is the Pound ſterling, containing 20 ſhillings; in France the Pound or livre Tournois and Pariſis; in Holland and Flanders, a Pound or livre de gros, &c.—The term aroſe from hence, that the ancient pound ſterling, though it only contained 240 pence, as ours does; yet each penny being equal to five of ours, the pound of ſilver weighed a Pound troy.

POUNDER, in Artillery, a term uſed to [illegible] certain weight of ſhot or ball, or how many [illegible] weight the proper ball is for any cannon [illegible] pounder, a 12 pounder, &c.

POWDER, *Gun*. See Gunpowder.

Powder-*Tricks*. See Eprouvette.

POWER, in Mechanics, denotes ſome force which, being applied to a machine, tends to produce motion; whether it does actually produce it or not. In the former caſe, it is called a moving Power; in the latter, a ſuſtaining power.

Power is alſo uſed in Mechanics, for any of the ſix ſimple machines, viz. the lever, the balance, the ſcrew, the wheel and axle, the wedge, and the pulley.

Power *of a Glaſs*, in Optics, is by ſome uſed for the diſtance between the convexity and the ſolar focus.

Power, in Arithmetic, the produce of a number, or other quantity, ariſing by multiplying it by itſelf, any number of times.

Any number is called the firſt power of itſelf. If it be multiplied once by itſelf, the product is the ſecond power, or ſquare; if this be multiplied by the firſt power again, the product is the third power, or cube; if this be multiplied by the firſt power again, the product is the fourth power, or biquadratic; and ſo on; the Power being always denominated from the number which exceeds the multiplications by one or unity, which number is called the index or exponent of the Power, and is now ſet at the upper corner towards the right of the given quantity or root, to denote or expreſs the Power. Thus,

3	or 3^1 =	3 is the 1ſt power of 3,
3×3	or 3^2 =	9 is the 2d power of 3,
$3^2 \times 3$	or 3^3 =	27 is the 3d power of 3,
$3^3 \times 3$	or 3^4 =	81 is the 4th power of 3,
&c.		&c.

Hence, to raiſe a quantity to a given Power or dignity, is the ſame as to find the product ariſing from its being multiplied by itſelf a certain number of times; for example, to raiſe 2 to the 3d power, is the ſame thing as to find the factum, or product $8 = 2 \times 2 \times 2$. The operation of raiſing Powers, is called Involution.

Powers, of the ſame degree, are to one another in the ratio of the roots as manifold as their common exponent contains units: thus, ſquares are in a duplicate ratio of the roots; cubes in a triplicate ratio; 4th powers in a quadruplicate ratio.—And the Powers of proportional quantities are alſo proportional to one another: ſo, if $a : b :: c : d$, then, in any Powers alſo, $a^n : b^n :: c^n : d^n$.

The particular names of the ſeveral Powers, as introduced by the Arabians, were, ſquare, cube, quadrato-quadratum or biquadrate, ſurſolid, cube ſquared, ſecond ſurſolid, quadrato-quadrato-quadratum, cube of the cube,

cube, ſquare of the ſurſolid, third ſurſolid, and ſo on, according to the *products* of the indices.

And the names given by Diophantus, who is followed by Vieta and Oughtred, are, the ſide or root, ſquare, cube, quadrato-quadratum, quadrato-cubus, cubo-cubus, quadrato-quadrato-cubus, quadrato-cubo-cubus, cubo-cubo-cubus, &c, according to the *ſums* of the indices.

But the moderns, after Des Cartes, are contented to diſtinguiſh moſt of the Powers by the exponents; as 1ſt, 2d, 3d, 4th, &c.

The characters by which the ſeveral Powers are denoted, both in the Arabic and Carteſian notation are as follow:

Arab.	1	*R*	*q*	*c*	*bq*	*s*	*qc*	*Bſ*	*tq*	*lc*
Cart.	a^0	a^1	a^2	a^3	a^4	a^5	a^6	a^7	a^8	a^9
	1	2	4	8	16	32	64	128	256	512

Hence, 1ſt. The Powers of any quantity, form a ſeries of geometrical proportionals, and their exponents a ſeries of arithmetical proportionals, in ſuch ſort that the addition of the latter anſwers to the multiplication of the former, and the ſubtraction of the latter anſwers to the diviſion of the former, &c; or in ſhort, that the latter, or exponents, are as the logarithms of the former, or Powers.

Thus, $a^2 \times a^3 = a^5$, and $2 + 3 = 5$;
$4 \times 8 = 32$;
alſo $a^5 \div a^3 = a^2$, and $5 - 3 = 2$;
$32 \div 8 = 4$.

2d. The 0 Power of any quantity, as a^0, is $= 1$.

3d. Powers of the ſame quantity are multiplied, by adding their exponents: Thus,

Mult. by	a^3	x^2	y^m	x^m	a^3
	a^4	x^4	y^m	x^n	a^n
Prod.	a^7	x^6	y^{2m}	x^{m+n}	a^{3+n}

4th. Powers are divided by ſubtracting their exponents. Thus,

Div. by	a^7	x^6	y^{2m}	x^{m+n}	a^{3+n}
	a^3	x^2	y^m	x^m	a^3
Quot.	a^4	x^4	y^m	x^n	a^n

5th. Powers are alſo conſidered as negative ones, or having negative exponents, when they denote a diviſor, or the denominator of a fraction. So $\frac{1}{a^3} = a^{-3}$, and $\frac{2}{a^2} = 2a^{-2}$, and $\frac{a^2}{x^4} = a^2 x^{-4}$, &c.

And hence any quantity may be changed from the denominator to the numerator, or from a diviſor to a multiplier, or vice verſa, by changing the ſign of its exponent; and the whole ſeries of Powers proceeds indefinitely both ways from 1 or the 0 Power, poſitive on the one hand, and negative on the other. Thus,

&c a^{-4} a^{-3} a^{-2} a^{-1} a^0 a^1 a^2 a^3 a^4 &c,

or &c $\frac{1}{a^4}$ $\frac{1}{a^3}$ $\frac{1}{a^2}$ $\frac{1}{a}$ 1 a a^2 a^3 a^4 &c.

Powers are alſo denoted with fractional exponents, or even with ſurd or irrational ones; and then the numerator denotes the Power raiſed to, and the denominator the exponent of ſome root to be extracted: Thus,

$\sqrt{a} = a^{\frac{1}{2}}$, and $\sqrt{a^3} = a^{\frac{3}{2}}$, and $\sqrt[3]{a^2} = a^{\frac{2}{3}}$, &c.

And theſe are ſometimes called imperfect powers, or ſurds.

When the quantity to be raiſed to any Power is poſitive, all its Powers muſt be poſitive. And when the radical quantity is negative, yet all its even Powers muſt be poſitive: becauſe $-\times-$ gives $+$: the odd Powers only being negative, or when their exponents are odd numbers: Thus, the Powers of $-a$,

are $+1$, $-a$, $+a^2$, $-a^3$, $+a^4$, $-a^5$, $+a^6$, &c.

where the even Powers a^2, a^4, a^6 are poſitive,
and the odd Powers a, a^3, a^5 are negative.

Hence, if a Power have a negative ſign, no even root of it can be aſſigned; ſince no quantity multiplied by itſelf an even number of times, can give a negative product. Thus $\sqrt{-a^2}$, or the ſquare or 2d root of $-a^2$, cannot be aſſigned; and is called an impoſſible root, or an imaginary quantity.—Every Power has as many roots, real and imaginary, as there are units in the exponent.

M. De la Hire gives a very odd property common to all Powers. M. Carre had obſerved with regard to the number 6, that all the natural cubic numbers, 8, 27, 64, 125, having their roots leſs than 6, being divided by 6, the remainder of the diviſion is the root itſelf; and if we go farther, 216, the cube of 6, being divided by 6, leaves no remainder; but the diviſor 6 is itſelf the root. Again, 343, the cube of 7, being divided by 6, leaves 1; which added to the diviſor 6, makes the root 7, &c. M. De la Hire, on conſidering this, has found that all numbers, raiſed to any Power whatever, have diviſors, which have the ſame effect with regard to them, that 6 has with regard to cubic numbers. For finding theſe diviſors, he diſcovered the following general rule, viz, If the exponent of the Power of a number be even, i. e. if the number be raiſed to the 2d, 4th, 6th, &c Power, it muſt be divided by 2; the remainder of the diviſion, when there is any, added to 2, or to a multiple of 2, gives the root of this number, correſponding to its Power, i. e. the 2d, 6th, &c root.

But if the exponent of the power be an uneven number, i. e. if the number be raiſed to the 3d, 5th, 7th, &c Power; the double of this exponent will be the diviſor, which has the property abovementioned. Thus is it found in 6, the double of 3, the exponent of the Power of the cubes: ſo alſo 10, the double of 5, is the diviſor of all 5th Powers; &c.

Any Power of the natural numbers 1, 2, 3, 4, 5, 6, &c, as the nth Power, has as many orders of differences as there are units in the common exponent of all the numbers; and the laſt of theſe differences is a conſtant quantity, and equal to the continual product $1 \times 2 \times 3 \times 4 \times \text{-------} \times n$, continued till the laſt factor, or the number of factors, be n, the exponent of the Powers. Thus,

the 1st Powers 1, 2, 3, 4, 5, &c, have but one order of differences 1 1 1 1 &c, and that difference is 1.

The 2d Pwrs. 1, 4, 9, 16, 25, &c, have two orders of differences 3 5 7 9
2 2 2

and the last of these is 2 = 1 × 2.

The 3d Pwrs. 1, 8, 27, 64, 125, &c, have three orders of differences 7 19 37 61
12 18 24
6 6

and the last of these is 6 = 1 × 2 × 3.

In like manner, the 4th or last differences of the 4th Powers, are each 24 = 1 × 2 × 3 × 4; and the 5th or last differences of the 5th Powers, are each 120 = 1 × 2 × 3 × 4 × 5. And so on. Which property was first noticed by Peletarius.

And the same is true of the Powers of any other arithmetical progression 1, 1 + d, 1 + 2d, 1 + 3d, &c,

viz, 1, $\overline{1+d}^{n}$, $\overline{1+2d}^{n}$, $\overline{1+3d}^{n}$, &c,

the number of the orders of differences being still the same exponent n, and the last of those orders each equal to 1 × 2 × 3 ------ × nd^{n}, the same product of factors as before, multiplied by the same Power of the common difference d of the series of roots: as was shewn by Briggs.

And hence arises a very easy and general way of raising all the Powers of all the natural numbers, viz, by common addition only, beginning at the last differences, and adding them all continually, one after another, up to the Powers themselves. Thus, to generate the series of cubes, or 3d Powers, adding always 6, the common 3d difference gives the 2d differences 12, 18, 24, &c; and these added to the 1st of the 1st differences 7, gives the rest of the said 1st differences; and these again added to the 1st cube 1, gives the rest of the series of cubes, 8, 27, 64, &c, as below.

			&c.

Commensurable in POWER, is said of quantities which, though not commensurable themselves, have their squares, or some other Power of them, commensurable. Euclid confines it to squares. Thus, the diagonal and side of a square are commensurable in Power, their squares being as 2 to 1, or commensurable; though they are not commensurable themselves, being as $\sqrt{2}$ to 1.

POWER *of an Hyperbola*, is the square of the 4th part of the conjugate axis.

PRACTICAL Arithmetic, Geometry, Mathematics, &c, is the part that regards the practice, or application, as contradistinguished from the theoretical part.

PRACTICE, in Arithmetic, is a rule which expeditiously and compendiously answers questions in the golden rule, or rule-of-three, especially when the first term is 1. See rules for this purpose in all the books of practical arithmetic.

PRECESSION *of the Equinoxes*, is a very slow motion of them, by which they change their place, going from east to west, or backward, *in antecedentia*, as astronomers call it, or contrary to the order of the signs.

From the late improvements in astronomy it appears, that the pole, the solstices, the equinoxes, and all the other points of the ecliptic, have a retrograde motion and are constantly moving from east to west, or from Aries towards Pisces, &c; by means of which, the equinoctial points are carried farther and farther back, among the preceding signs or stars, at the rate of about 50″¼ each year; which retrograde motion is called the Precession, Recession, or Retrocession of the Equinoxes.

Hence, as the stars remain immoveable, and the equinoxes go backward, the stars will seem to move more and more eastward with respect to them; for which reason the longitudes of all the stars, being reckoned from the first point of Aries, or the vernal equinox, are continually increasing.

From this cause it is, that the constellations seem all to have changed the places assigned to them by the ancient astronomers. In the time of Hipparchus, and the oldest astronomers, the equinoctial points were fixed to the first stars of Aries and Libra: but the signs do not now answer to the same points; and the stars which were then in conjunction with the sun when he was in the equinox, are now a whole sign, or 30 degrees, to the eastward of it: so, the first star of Aries is now in the portion of the ecliptic, called Taurus; and the stars of Taurus are now in Gemini; and those of Gemini in Cancer; and so on.

This seeming change of place in the stars was first observed by Hipparchus of Rhodes, who, 128 years before Christ, found that the longitudes of the stars in his time were greater than they had been before observed by Tymochares, and than they were in the sphere of Eudoxus, who wrote 380 years before Christ. Ptolomy also perceived the gradual change in the longitudes of the stars; but he stated the quantity at too little, making it but 1° in 100 years, which is at the rate of only 36″ per year. Y-hang, a Chinese, in the year 721, stated the quantity of this change at 1° in 83 years, which is at the rate of 43″½ per year. Other more modern astronomers have made this precession still more, but with some small differences from each other; and it is now usually taken at 50″¼ per year. All these rates are deduced from a comparison of the longitude of certain stars as observed by more ancient astronomers, with the later observations of the same stars; viz, by subtracting the former from the latter, and dividing the remainder by the number of years in the interval between the dates of the observations. Thus, by a medium of a great number of comparisons, the quantity of the annual change has been fixed at 50″¼, according to which rate it will require 25791 years for the equinoxes to make their revolution westward quite around the circle, and return to the same point again.

Thus

Thus, by taking the longitudes of the principal ſtars eſtabliſhed by Tycho Brahe, in his book Aſtronomiæ Inſtauratæ Progymnaſmata, pa. 208 and 232, for the beginning of 1586, and comparing them with the ſame as determined for the year 1750, by M. de la Caille, for that interval of 164 years, there will be obtained the following differences of longitude of ſeveral ſtars; viz,

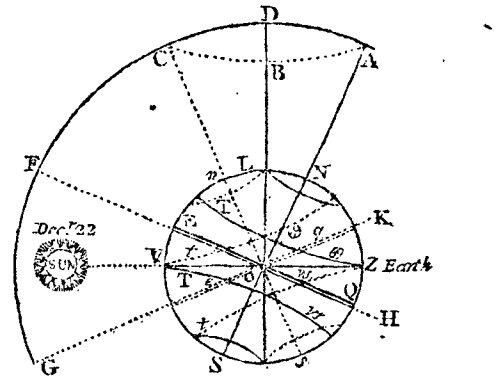
γ	Arietis	2°	17′	37″
	Aldebaran	2	17	45
μ	Geminorum	2	17	1
β	Geminorum	2	15	26
	Regulus	2	16	32
α	Virginis	2	18	18
α	Aquilæ	2	19	1
α	Pegaſi	2	16	12
β	Libræ	2	17	52
	Antares	2	16	28
ε	Tauri	2	17	58
γ	Geminorum	2	18	38
γ	Cancri	2	19	12
γ	Leonis	2	19	38
γ	Capricorni	2	16	10
	Medium of theſe 15 ſtars	2	17	35

which divided by 164, the interval of years, gives 50″·336, or nearly 50″⅓, or after the rate of 1° 23′ 53″⅓ in 100 years, or 25,748 years for the whole revolution, or circle of 360 degrees. And nearly the ſame concluſion reſults from the longitudes of the ſtars in the Britannic catalogue, compared with thoſe of the ſtill later catalogues. See De la Lande's Aſtronomie, in ſeveral places.

The Ancients, and even ſome of the Moderns, have taken the equinoxes to be immoveable; and aſcribed that change in the diſtance of the ſtars from it, to a real motion of the orb of the fixed ſtars, which they ſuppoſed had a ſlow revolution about the poles of the ecliptic; ſo as that all the ſtars perform their circuits in the ecliptic, or its parallels, in the ſpace of 25,791 years; after which they ſhould all return again to their former places.

This period the Ancients called the Platonic, or great year; and imagined that at its completion every thing would begin as at firſt, and all things come round in the ſame order as they have done before.

The phenomena of this retrograde motion of the equinoxes, or interſections of the equinoctial with the ecliptic, and conſequently of the conical motion of the earth's axis, by which the pole of the equator deſcribes a ſmall circle in the ſame period of time, may be underſtood and illuſtrated by a ſcheme, as follows: Let NZSVL be the earth, SONA its axis produced to the ſtarry heavens, and terminating in A, the preſent north pole of the heavens, which is vertical to N, the north pole of the earth. Let EOQ be the equator, T♋Z the tropic of cancer, and VT♑ the tropic of capricorn; VOZ the ecliptic, and BO its axis; both of which are immoveable among the ſtars. But as the equinoctial points recede in the ecliptic, the earth's axis SON is in motion upon the earth's centre O, in ſuch a manner as to deſcribe the double cone NO*n*



and SO*s*, round the axis of the ecliptic BO, in the time that the equinoctial points move round the ecliptic, which is 25,791 years; and in that length of time, the north pole of the earth's axis, produced, deſcribes the circle ABCDA in the ſtarry heavens, round the pole of the ecliptic, which keeps immoveable in the centre of that circle. The earth's axis being now 23° 28′ inclined to the axis of the ecliptic, the circle ABCDA, deſcribed by the north pole of the earth's axis produced to A, is 46° 56′ in diameter, or double the inclination of the earth's axis. In conſequence of this, the point A, which is at preſent the north pole of the heavens, and near to a ſtar of the 2d magnitude in the end of the Little Bear's tail, muſt be deſerted by the earth's axis; which moving backwards 1 degree every 71½ years nearly, will be directed towards the ſtar or point B in 6447¾ years hence; and in double of that time, or 12,895½ years, it will be directed towards the ſtar or point C; which will then be the north pole of the heavens, although it is at preſent 8½ degrees ſouth of the zenith of London L. The preſent poſition of the equator EOQ will then be changed into *e*O*q*, the tropic of cancer T♋Z into V*t*♋, and the tropic of capricorn VT♑ into *v*♑Z; as is evident by the figure. And the ſun, in the ſame part of the heavens where he is now over the earthly tropic of capricorn, and makes the ſhorteſt days and longeſt nights in the northern hemiſphere, will then be over the earthly tropic of cancer, and make the days longeſt and nights ſhorteſt. So that it will require 12,895½ years yet more, or from that time, to bring the north pole N quite round, ſo as to be directed toward that point of the heavens which is vertical to it at preſent. And then, and not till then, the ſame ſtars which at preſent deſcribe the equator, tropics, and polar circles, &c, by the earth's diurnal motion, will deſcribe them over again.

From this ſhifting of the equinoctial points, and with them all the ſigns of the ecliptic, it follows, that thoſe ſtars which in the infancy of aſtronomy were in Aries, are now found in Taurus; thoſe of Taurus in Gemini, &c. Hence likewiſe it is, that the ſtars which roſe or ſet at any particular ſeaſon of the year, in the times of Heſiod, Eudoxus, Virgil, Pliny, &c, by

by no means anſwer at this time to their deſcriptions.

As to the phyſical cauſe of the Preceſſion of the equinoxes, Sir Iſaac Newton demonſtrates, that it ariſes from the broad or flat ſpheroidal figure of the earth; which itſelf ariſes from the earth's rotation about its axis: for as more matter has thus been accumulated all round the equatorial parts than any where elſe on the earth, the ſun and moon, when on either ſide of the equator, by attracting this redundant manner, bring the equator ſooner under them, in every return towards it, than if there was no ſuch accumulation.

Sir Iſaac Newton, in determining the quantity of the annual Preceſſion from the theory of gravity, on ſuppoſition that the equatorial diameter of the earth is to the polar diameter, as 230 to 229, finds the ſun's action ſufficient to produce a Preceſſion of $9''\frac{1}{8}$ only; and collecting from the tides the proportion between the ſun's force and the moon's to be as 1 to $4\frac{1}{2}$, he ſettles the mean Preceſſion reſulting from their joint actions, at 50″; which, it muſt be owned, is nearly the ſame as it has ſince been found by the beſt obſervations; and yet ſeveral other mathematicians have ſince objected to the truth of Sir Iſaac Newton's computation.

Indeed, to determine the quantity of the Preceſſion ariſing from the action of the ſun, is a problem that has been much agitated among modern mathematicians; and although they ſeem to agree as to Newton's miſtake in the ſolution of it, they have yet generally diſagreed from one another. M. D'Alembert, in 1749, printed a treatiſe on this ſubject, and claims the honour of having been the firſt who rightly determined the method of reſolving problems of this kind. The ſubject has been alſo conſidered by Euler, Friſius, Silvabelle, Walmeſley, Simpſon, Emerſon, La Place, La Grange, Landen, Milner, and Vince.

M. Silvabelle, ſtating the ratio of the earth's axis to be that of 178 to 177, makes

the annual Preceſſion cauſed by the ſun 13″ 52‴,
and that of the moon - - 34 17;

making the ratio of the lunar force to the ſolar, to be that of 5 to 2; alſo the nutation of the earth's axis cauſed by the moon, during the time of a ſemirevolution of the pole of the moon's orbit, i. e. in $9\frac{1}{3}$ years, he makes 17″ 51‴.—M. Walmeſley, on the ſuppoſition that the ratio of the earth's diameters is that of 230 to 229, and the obliquity of the ecliptic to the equator 23° 28′ 30″, makes the annual Preceſſion, owing to the ſun's force, equal to 10″·583; but ſuppoſing the ratio of the diameters to be that of 178 to 177, that Preceſſion will be 13″·675.—Mr. Simpſon, by a different method of calculation, determines the whole annual preceſſion of the equinoxes cauſed by the ſun, at 21″ 6‴; and he has pointed out the errors of the computations propoſed by M. Silvabelle and M. Walmeſley.—Mr. Milner's deduction agrees with that of Mr. Simpſon, as well as Mr. Vince's; and their papers contain beſides ſeveral curious particulars relative to this ſubject. But for the various principles and reaſonings of theſe mathematicians, ſee Philoſ. Tranſ. vol. 48, pa. 385; vol. 49, pa. 704; vol. 69, pa. 505; and vol. 77. pa. 363; as alſo the writings of Simpſon, Emerſon, Landen, &c; alſo De la Lande's Aſtronomie, and the Memoirs of the Acad. Sci. in ſeveral places.

As to the effect of the planets upon the equinoctial points, M. De la Place, in his new reſearches on this article, finds that their action cauſes thoſe points to advance by 0″·2016 in a year, along the equator, or 0″·1849 along the ecliptic; from whence it follows that the quantity of the luni-ſolar Preceſſion muſt be 50″·4349, ſince the total obſerved Preceſſion is $50''\frac{1}{4}$, or 50″·25.

To find the Preceſſion in right aſcenſion and declination.

Put d = the declination of a ſtar,
and a = its right aſcenſion;

then their annual variations of Preceſſions will be nearly as follow:

viz, 20″·084 × cof. a = the annual preceſ. in declinat. and 46″·0619 + 20″·084 × ſin. a × tang. d = that of right aſcenſion. See the Connoiſſance des Temps for 1792, pa. 206, &c.

PRESS, in Mechanics, is a machine made of iron or wood, ſerving to compreſs or ſqueeze any body very cloſe, by means of ſcrews.

The common Preſſes conſiſt of ſix members, or pieces; viz, two flat and ſmooth planks; between which the things to be preſſed are laid; two ſcrews, or worms, faſtened to the lower plank, and paſſing through two holes in the upper; and two nuts, ſerving to drive the upper plank, which is moveable, againſt the lower, which is ſtable, and without motion.

PRESSION. See PRESSURE.

PRESSURE, is properly the action of a body which makes a continual effort or endeavour to move another; ſuch as the action of a heavy body ſupported by a horizontal table; in contradiſtinction from percuſſion, or a momentary force or action. Preſſure equally reſpects both bodies, that which preſſes, and that which is preſſed; from the mutual equality of action and reaction.

Preſſure, in the Carteſian Philoſophy, is an impulſive kind of motion, or rather an endeavour to move, impreſſed on a fluid medium, and propagated through it. In ſuch a preſſure the Carteſians ſuppoſe the action of light to conſiſt. And in the various modifications of this Preſſure, by the ſurfaces of bodies, on which that medium preſſes, they ſuppoſe the various colours to conſiſt, &c. But Newton ſhews, that if light conſiſted only in a Preſſure, propagated without actual motion, it could not agitate and warm ſuch bodies as reflect and refract it, as we actually find it does; and if it conſiſted in an inſtantaneous motion, or one propagated to all diſtances in an inſtant, as ſuch Preſſure ſuppoſes, there would be required an infinite force to produce that motion every moment, in every lucid particle. Farther, if light conſiſted either in Preſſure, or in motion propagated in a fluid medium, whether inſtantaneouſly, or in time, it muſt follow, that it would inflect itſelf *ad umbram*; for Preſſure, or motion, in a fluid medium, cannot be propagated in right lines, beyond any obſtacle which ſhall hinder any part of the motion; but will inflect and diffuſe itſelf, every way, into thoſe parts of the quieſcent medium which lie beyond the ſaid obſtacle.

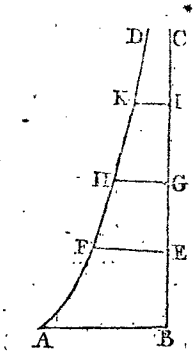
Thus

Thus the force of gravity tends downward; but the Preſſure which ariſes from that force of gravity, tends every way with an equable force; and, with equal eaſe and force, is propagated in crooked lines, as in ſtraight ones. Waves on the ſurface of water, while they ſlide by the ſides of any large obſtacle, do inflect, dilate, and diffuſe themſelves gradually into the quieſcent water lying beyond the obſtacle. The waves, pulſes, or vibrations of the air, in which ſounds conſiſt, do manifeſtly inflect themſelves, though not ſo much as the waves of water; for the ſound of a bell, or of a cannon, can be heard over a hill, which intercepts the ſonorous object from our ſight; and ſounds are propagated as eaſily through crooked tubes, as through ſtraight ones. But light is never obſerved to go in curved lines, nor to inflect itſelf *ad umbram*; for the fixed ſtars do immediately diſappear on the interpoſition of any of the planets; as well as ſome parts of the ſun's body, by the interpoſition of the Moon, or Venus, or Mercury.

PRESSURE *of Air, Water, &c.* See AIR, WATER, &c.

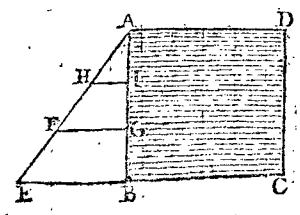
The effects anciently aſcribed to the fuga vacui, are now accounted for from the weight and Preſſure of the air.

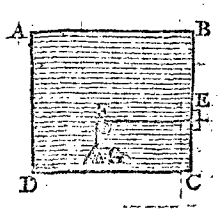
The Preſſure of the air on the ſurface of the earth, is balanced by a column of water of the ſame baſe, and about 34 feet high; or of one of Mercury of near 30 inches high; and upon every ſquare inch at the earth's ſurface, that Preſſure amounts to about $14\frac{3}{4}$ pounds avoirdupois. The elaſticity of the air is equal to that Preſſure, and by means of that Preſſure, or elaſticity, the air would ruſh into a vacuum with a velocity of about 1370 feet per ſecond. At different heights above the earth's ſurface, the Preſſure of the air is as its denſity and elaſticity, and each decreaſes in ſuch ſort, that when the heights above the ſurface increaſe in arithmetical progreſſion, the Preſſure &c decreaſe in geometrical progreſſion: and hence if the axis BC of a logarithmic curve AD be erected perpendicular to the horizon, and if the ordinate AB denote the Preſſure, or elaſticity, or denſity of the air, at the earth's ſurface, then will any other abſciſs



EF, GH, IK } denote the Preſſure &c at the altitude { BE, BG, BI,

The Preſſure of water, as this fluid is every where of the ſame denſity, is as its depth at any place, and in all directions the ſame; and upon a ſquare foot of ſurface, every foot in height preſſes with the force of a weight of 1000 ounces or $62\frac{1}{2}$lbs avoirdupois. And hence, if AB be the depth





of water in any veſſel, and BE denote its Preſſure at the depth B; by joining AE and drawing any other ordinates FG, HI; then ſhall theſe ordinates FG, HI, &c, denote the Preſſure at the correſponding depths AG, AI, &c; alſo the area of the triangle ABE will denote the whole Preſſure againſt the whole upright ſide AB, and which therefore is but half the Preſſure on the bottom of the ſame area as the ſide. Moreover, if a hole were opened in the bottom or ſide of the veſſel at B, the water, from the Preſſure of the ſuperincumbent fluid, would iſſue out with the velocity of $8\sqrt{AB}$ feet per ſecond nearly; AB being eſtimated in feet.

Centre of PRESSURE, in Hydroſtatics, is that point of any plane, to which, if the total Preſſure were applied, its effect upon the plane would be the ſame as when it was diſtributed unequally over the whole; or it is that point in which the whole Preſſure may be conceived to be united; or it is that point to which, if a force were applied equal to the total Preſſure, but with an oppoſite direction, it would exactly balance, or reſtrain the effect of the Preſſure, ſo that the body preſſed on will not incline to either ſide. Thus, if ABCD (2d fig. above) be a veſſel of water, and the ſide BC be preſſed upon with a force equivalent to 20 pounds of water, this force is unequally diſtributed over BC, for the parts near B are leſs preſſed than thoſe near C, which are at a greater depth; and therefore the efforts of all the particular Preſſures are united in ſome point E, which is nearer to C than to B; and that point E is called the centre of Preſſure: if to that point a force equivalent to 20 pounds weight be applied, it will affect the plane BC in the ſame manner as by the Preſſure of the water diſtributed unequally over the whole; and if to the ſame point the ſame force be applied in a contrary direction to that of the Preſſure of the water, the force and the Preſſure will balance each other, and by oppoſite endeavours deſtroy each other's effects. Suppoſing a cord EFG fixed at E, and paſſing over the pulley F, has a weight of 20 pounds annexed to it, and that the part of the cord FE is perpendicular to BC; then the effort of the weight G is equal, and its direction contrary, to that of the Preſſure of the water. Now if E be the centre of Preſſure, theſe two powers will be in equilibrio, and mutually defeat each other's endeavours.

This point E, or the centre of Preſſure, is the ſame with the centre of percuſſion of the plane BC, the point of ſuſpenſion being B, the ſurface of the water. And if the plane be oblique, the caſe is ſtill the ſame, taking for the axis of ſuſpenſion, the interſection of that plane and the ſurface of the fluid, both produced if neceſſary. See Cotes's Lectures, pa. 40, &c.

The centre of Preſſure upon a plane parallel to the horizon, or upon any plane where the Preſſure is uniform, is the ſame as the centre of gravity of that plane. For the Preſſure acts upon every part in the ſame manner as gravity does.

PRIMARY *Planets*, are thoſe which revolve round the ſun as a centre. Such are the planets Mercury, Venus, Terra the Earth, Mars, Jupiter, Saturn, and Herſchel, and perhaps others. They are thus called, in contradiſtinction from the ſecondary planets, or ſatellites, which revolve about their reſpective Primaries. See PLANET.

PRIMES, denote the firſt diviſions into which ſome whole or integer is divided. As, a minute, or Prime minute, the 60th part of a degree; or the firſt place of decimals, being the 10th parts of units; or the firſt diviſion of inches in duodecimals, being the 12th parts of inches; &c.

PRIME *Numbers*, are thoſe which can only be meaſured by unity, or exactly divided without a remainder, 1 being the only aliquot part: as 2, 3, 5, 7, 11, 13, 17, &c. And they are otherwiſe called Simple, or Incompoſite numbers. No even number is a Prime, becauſe every even number is diviſible by 2. No number that ends with 0 or 5 is a Prime, the former being diviſible by 10, and the latter by 5. The following Table contains all the Prime numbers, and all the odd compoſite numbers, under 10,000, with the leaſt Prime diviſors of theſe; the deſcription, nature, and uſe of which, ſee immediately following the Table.

A Table of Prime and Compoſite Odd Numbers, under 10,000.

Out of the foregoing Table, are omitted all the odd numbers that end with 5, becauſe it is known that 5 is a diviſor, or aliquot part of every ſuch number.—— The diſpoſition of the Prime and compoſite odd numbers in this Table, is along the top line, and down the firſt or left-hand column; while their leaſt Prime diviſors are placed in the angles of meeting in the body of the page. Thus, the figures along the top line, viz, 0, 1, 2, 3, 4, &c, to 99, are ſo many hundreds; and thoſe down the firſt column, from 1 to 99 alſo, are units or ones; and the former of theſe ſet before the latter, make up the whole number, whether it be Prime or compoſite; juſt like the diſpoſition of the natural numbers in a table of logarithms. So the 16 in the top line, joined with the 19 in the firſt column, makes the number 1619: the angle of their meeting, viz, of the column under 16, and of the line of 19, being blank, ſhews that the number 1619 has no aliquot part or diviſor, or that it is a Prime number. In like manner, all the other numbers are Primes that have no figure in their angle of meeting, as the numbers 41, 401, 919, &c. But when the two parts of any number have ſome figure in their angle of meeting, that figure is the leaſt diviſor of the number, which is therefore not a Prime, but a compoſite number: ſo 301 has 7 for its leaſt diviſor, and 803 has 11 for its leaſt diviſor, and 1633 has 23 for its leaſt diviſor.

Hence, by the foregoing Table, are immediately known at ſight all the Prime numbers up to 10,000; and hence alſo are readily found all the diviſors or aliquot parts of the compoſite numbers, namely in this manner: Find the leaſt diviſor of the given number in the Table, as above; divide the given number by this diviſor, and conſider the quotient as another or new number, of which find the leaſt diviſor alſo in the Table, dividing the ſaid quotient by this laſt diviſor; and ſo on, dividing always the laſt quotient by its leaſt diviſor found in the Table, till a quotient be found that is a Prime number: then are the ſaid diviſors and the laſt or Prime quotient, all the ſimple or Prime diviſors of the firſt given number; and if theſe ſimple diviſors be multiplied together thus, viz, every two, and every three, and every four, &c, of them together, the ſeveral products will make up the compound diviſors or aliquot parts of the firſt given number; noting, that if the given number be an even one, divide it by 2 till an odd number come out.

For example, to find all the diviſors or component factors of the number 210. This being an even number, dividing it by 2, one of its diviſors, gives 105; and this ending with 5, dividing it by 5, another of its factors, gives 21; and the leaſt diviſor of 21, by the Table is 3, the quotient from which is 7; therefore all the Prime or ſimple factors of the given number are 2, 3, 5, 7. Set theſe therefore down in the firſt line as in the margin; then multiply the 2 by the 3, and ſet the product 6 below the 3; next multiply the 5 by all that precede it, viz, 2, 3, 6, and ſet the products below the 5; laſtly multiply the 7 by all the ſeven factors preceding it, and ſet the products below the 7; ſo ſhall we have all the factors or diviſors of the given number 210, which are theſe, viz,

2	3	5	7
	6	10	14
		15	21
		30	42
			35
			70
			105
			210

2, 3, 5, 6, 7, 10, 14, 15, 21, 30, 35, 42, 70, 105.

PRIME *Vertical*, is that vertical circle, or azimuth, which is perpendicular to the meridian, and paſſes through the eaſt and weſt points of the horizon.

PRIME *Verticals*, in Dialling, or PRIME-*Vertical* Dials, are thoſe that are projected on the plane of the Prime vertical circle, or on a plane parallel to it. Theſe are otherwiſe called direct, erect, north, or ſouth dials.

PRIME *of the Moon*, is the new moon at her firſt appearance, for about 3 days after her change. It means alſo the GOLDEN *Number*; which ſee.

PRIMUM *Mobile*, in the Ptolomaic Aſtronomy, is ſuppoſed to be a vaſt ſphere, whoſe centre is that of the world, and in compariſon of which the earth is but a point. This they deſcribe as including all other ſpheres within it, and giving motion to them, turning itſelf and all the reſt quite round in 24 hours.

PRINCIPAL, in Arithmetic, or in Commerce, is the ſum lent upon intereſt, either ſimple or compound.

PRINCIPAL *Point*, in Perſpective, is a point in the perſpective plane, upon which falls the principal ray, or line from the eye perpendicular to the plane. This point is in the interſection of the horizontal and vertical planes; and is alſo called the *point of ſight*, and *point of the eye*, or *centre of the picture*, or again the *point of concurrence*.

PRINCIPAL *Ray*, in Perſpective, is that which paſſes from the ſpectator's eye perpendicular to the picture or perſpective plane, and ſo meeting it in the principal point.

PRINGLE (Sir JOHN), Baronet, the late worthy preſident of the Royal Society, was born at Stichelhouſe, in the county of Roxburgh, North Britain, April 10, 1707. His father was Sir John Pringle, of Stichel, Bart. and his mother Magdalen Elliott, was ſiſter to Sir Gilbert Elliott, of Stobs, Baronet. He was the youngeſt of ſeveral ſons, three of whom, beſides himſelf, arrived to years of maturity. After receiving his grammatical education at home, he was ſent to the univerſity of St. Andrews, where having ſtaid ſome years, he removed to Edinburgh in 1727, to ſtudy phyſic, that being the profeſſion which he now determined to follow. He ſtaid however only one year at Edinburgh, being deſirous of going to Leyden, which was then the moſt celebrated ſchool for medicine in Europe. Dr. Boerhaave, who had brought that univerſity into great reputation, was conſiderably advanced in years, and Mr. Pringle was deſirous of benefiting by that great man's lectures. After having gone through his proper courſe of ſtudies at Leyden, he was admitted, in 1730, to his doctor of phyſic's degree; upon which occaſion his inaugural diſſertation, *De Marcore Senili*, was printed. On quitting Leyden, Dr. Pringle returned and ſettled at Edinburgh as a phyſician, where, in 1734, he was appointed, by the magiſtrates and council of the city, to be joint profeſſor of pneumatics and moral philoſophy with Mr. Scott, during this gentleman's life, and ſole profeſſor after his deceaſe; being alſo admitted at the ſame time a member of the univerſity. In diſcharging the duties of this new employment,

ment, his text-book was Puffendorff *de Officio Hominis et Civis*; agreeably to the method he purſued through life, of making fact and experiment the baſis of ſcience.

Dr. Pringle continued in the practice of Phyſic at Edinburgh, and in duly performing the office of profeſſor, till 1742, when he was appointed phyſician to the earl of Stair, who then commanded the Britiſh army. By the intereſt of this nobleman, Dr. Pringle was conſtituted, the ſame year, phyſician to the military hoſpital in Flanders, with a ſalary of 20 ſhillings a-day, and the right to half pay for life. On this occaſion he was permitted to retain his profeſſorſhip of moral philoſophy; two gentlemen, Meſſrs. Muirhead and Cleghorn teaching in his abſence, as long as he requeſted it. The great attention which Dr. Pringle paid to his duty as an army phyſician, is evident from every page of his *Treatiſe on the Diſeaſes of the Army*, in the execution of which office he was ſometimes expoſed to very imminent dangers. He ſoon after alſo met with no ſmall affliction in the retirement of his great friend the earl of Stair, from the army. He offered to reſign with his noble patron, but was not permitted: he was therefore obliged to content himſelf with teſtifying his reſpect and gratitude to him, by accompanying the earl 40 miles on his return to England; after which he took leave of him with the utmoſt regret.

But though Dr. Pringle was thus deprived of the immediate protection of a nobleman who knew and eſteemed his worth, his conduct in the duties of his ſtation procured him effectual ſupport. He attended the army in Flanders through the campaign of 1744, and ſo powerfully recommended himſelf to the duke of Cumberland, that in the ſpring following he had a commiſſion, appointing him phyſician-general to the king's forces in the Low Countries, and parts beyond the ſeas; and on the next day he received a ſecond commiſſion from the duke, conſtituting him phyſician to the royal hoſpitals in thoſe countries. In conſequence of theſe promotions, he the ſame year reſigned his profeſſorſhip in the univerſity of Edinburgh.

In 1745 he was alſo with the army in Flanders; but was recalled from that country in the latter end of the year, to attend the forces which were to be ſent againſt the rebels in Scotland. At this time he had the honour of being choſen F. R. S. and the Society had good reaſon to be pleaſed with the addition of ſuch a member. In the beginning of 1746, Dr. Pringle accompanied, in his official capacity, the duke of Cumberland in his expedition againſt the rebels; and remained with the forces, after the battle of Culloden, till their return to England the following ſummer. In 1747 and 1748, he again attended the army abroad; but in the autumn of 1748, he embarked with the forces for England, on the ſigning of the treaty of Aix-la-Chapelle.

From that time he moſtly reſided in London, where, from his known ſkill and experience, and the reputation he had acquired, he might reaſonably expect to ſucceed as a phyſician. In 1749 he was appointed phyſician in ordinary to the duke of Cumberland. And in 1750 he publiſhed, in a letter to Dr. Mead, *Obſervations on the Gaol or Hoſpital Fever*: this piece, with ſome alterations, was afterwards included in his grand work on the *Diſeaſes of the Army*.

In this, and the two following years Dr. Pringle communicated to the Royal Society his celebrated *Experiments upon Septic and Antiſeptic Subſtances, with Remarks relating to their Uſe in the Theory of Medicine*; ſome of which were printed in the Philoſophical Tranſactions, and the whole were ſubjoined, as an appendix, to his *Obſervations on the Diſeaſes of the Army*. Thoſe experiments procured for the ingenious author the honour of Sir Godfrey Copley's gold medal; beſides gaining him a high and juſt reputation as an experimental philoſopher. He gave alſo many other curious papers to the Royal Society: thus, in 1753, he preſented, *An Account of ſeveral Perſons ſeized with the Gaol Fever by working in Newgate; and of the Manner by which the Infection was communicated to one entire Family*; in the Philoſ. Tranſ. vol. 48. His next communication was, *A remarkable caſe of Fragility, Flexibility, and Diſſolution of the Bones*; in the ſame vol.—In the 49th volume, are accounts which he gave of an Earthquake felt at Bruſſels; of another at Glaſgow and Dunbarton; and of the Agitation of the Waters, Nov. 1, 1756, in Scotland and at Hamburgh.—The 50th volume contains his Obſervations on the Caſe of lord Walpole, of Woolleiton; and a Relation of the Virtues of Soap, in Diſſolving the Stone.—The next volume is enriched with two of the doctor's articles, of conſiderable length, as well as value. In the firſt, he hath collected, digeſted, and related, the different accounts that had been given of a very extraordinary Fiery Meteor, which appeared the 26th of November 1758; and in the ſecond he hath made a variety of remarks upon the whole, diſplaying a great degree of philoſophical ſagacity.—Beſides his communications in the Philoſophical Tranſactions, he gave, in the 5th volume of the Edinburgh Medical Eſſays, an Account of the Succeſs of the *Vitrum ceratum Antimonii*.

In 1752, Dr. Pringle married Charlotte, the ſecond daughter of Dr. Oliver, an eminent phyſician at Bath: a connection which however did not laſt long, the lady dying in the ſpace of a few years. And nearly about the time of his marriage, he gave to the public the firſt edition of his *Obſervations on the Diſeaſes of the Army*; which afterwards went through many editions with improvements, was tranſlated into the French, the German, and the Italian languages, and deſervedly gained the author the higheſt credit and encomiums. The utility of this work however was of ſtill greater importance than its reputation. From the time that the doctor was appointed a phyſician to the army, it ſeems to have been his grand object to leſſen, as far as lay in his power, the calamities of war; nor was he without conſiderable ſucceſs in his noble and benevolent deſign. The benefits which may be derived from our author's great work, are not ſolely confined to gentlemen of the medical profeſſion. General Melville, a gentleman who unites with his military abilities the ſpirit of philoſophy, and the feelings of humanity, was enabled, when governor of the Neutral Iſlands, to be ſingularly uſeful, in conſequence of the inſtructions he had received from Dr. Pringle's book, and from perſonal converſation with him. By taking care to have his men always lodged in large, open, and airy apartments, and by never letting his forces remain long enough in ſwampy places to be injured by the noxious air of ſuch places, the general was the

happy inſtrument of ſaving the lives of ſeven hundred ſoldiers.

Though Dr. Pringle had not for ſome years been called abroad, he ſtill held his place of phyſician to the army; and in the war that began in 1755, he attended the camps in England during three ſeaſons. In 1758, however, he entirely quitted the ſervice of the army; and being now determined to fix wholly in London, he was the ſame year admitted a licentiate of the college of phyſicians.—After the acceſſion of king George the 3d to the throne of Great Britain, Dr. Pringle was appointed, in 1761, phyſician to the queen's houſehold; and this honour was ſucceeded, by his being conſtituted, in 1763, phyſician extraordinary to the queen. The ſame year he was choſen a member of the Academy of Sciences at Haarlem, and elected a fellow of the Royal College of Phyſicians in London.—In 1764, on the deceaſe of Dr. Wollaſton, he was made phyſician in ordinary to the queen. In 1766 he was elected a foreign member, in the phyſical line, of the Royal Society of Sciences at Gottingen, and the ſame year he was raiſed to the dignity of a baronet of Great Britain. In 1768 he was appointed phyſician in ordinary to the late princeſs dowager of Wales.

After having had the honour to be ſeveral times elected into the council of the Royal Society, Sir John Pringle was at length, viz, Nov. 30, 1772, in conſequence of the death of James Weſt Eſq. elected preſident of that learned body. His election to this high ſtation, though he had ſo reſpectable a character as the late Sir James Porter for his opponent, was carried by a very conſiderable majority. Sir John Pringle's conduct in this honourable ſtation fully juſtified the choice the Society made of him as their preſident. By his equal, impartial, and encouraging behaviour, he ſecured the good will and beſt exertions of all for the general benefit of ſcience, and true intereſts of the Society, which in his time was raiſed to the pinnacle of honour and credit. Inſtead of ſplitting the members into oppoſite parties, by cruel, unjuſt, and tyrannical conduct, as has ſometimes been the caſe, to the ruin of the beſt intereſts of the Society, Sir John Pringle cheriſhed and happily united the endeavours of all, collecting and directing the energy of every one to the common good of the whole. He happily alſo ſtruck out a new way to diſtinction and uſefulneſs, by the diſcourſes which were delivered by him, on the annual aſſignment of Sir Godfrey Copley's medal. This gentleman had originally bequeathed five guineas, to be given at each anniverſary meeting of the Royal Society, by the determination of the preſident and council, to the perſon who ſhould be the author of the beſt paper of experimental obſervations for the year. In proceſs of time, this pecuniary reward, which could never be an important conſideration to a man of an enlarged and philoſophical mind, however narrow his circumſtances might be, was changed into the more liberal form of a gold medal; in which form it is become a truly honourable mark of diſtinction, and a juſt and laudable object of ambition. No doubt it was always uſual for the preſident, on the delivery of the medal, to pay ſome compliment to the gentleman on whom it was beſtowed; but the cuſtom of making a ſet ſpeech on the occaſion, and of entering into the hiſtory of that part of philoſophy to which the experiments, or the ſubject of the paper related, was firſt introduced by Martin Folkes Eſq. The diſcourſes however which he and his ſucceſſors delivered, were very ſhort, and were only inſerted in the minute-books of the Society. None of them had ever been printed before Sir John Pringle was raiſed to the chair. The firſt ſpeech that was made by him being much more elaborate and extended than uſual, the publication of it was deſired; and with this requeſt, it is ſaid, he was the more ready to comply, as an abſurd account of what he had delivered had appeared in a newspaper. Sir John was very happy in the ſubject of his firſt diſcourſe. The diſcoveries in magnetiſm and electricity had been ſucceeded by the inquiries into the various ſpecies of air. In theſe enquiries, Dr. Prieſtley, who had already greatly diſtinguiſhed himſelf by his electrical experiments, and his other philoſophical purſuits and labours, took the principal lead. A paper of his, intitled, *Obſervations on different Kinds of Air*, having been read before the Society in March 1772, was adjudged to be deſerving of the gold medal; and Sir John Pringle embraced with pleaſure the occaſion of celebrating the important communications of his friend, and of relating with accuracy and fidelity what had previouſly been diſcovered upon the ſubject.

It was not intended, we believe, when Sir John's firſt ſpeech was printed, that the example ſhould be followed: but the ſecond diſcourſe was ſo well received by the Society, that the publication of it was unanimouſly requeſted. Both the diſcourſe itſelf, and the ſubject on which it was delivered, merited ſuch a diſtinction. The compoſition of the ſecond ſpeech is evidently ſuperior to that of the former one; Sir John having probably been animated by the favourable reception of his firſt effort. His account of the Torpedo, and of Mr. Walſh's ingenious and admirable experiments relative to the electrical properties of that extraordinary fiſh, is ſingularly curious. The whole diſcourſe abounds with ancient and modern learning, and exhibits the worthy preſident's knowledge in natural hiſtory, as well as in medicine, to great advantage.

The third time that he was called upon to diſplay his abilities at the delivery of the annual medal, was on a very beautiful and important occaſion. This was no leſs than Mr. (now Dr.) Maſkelyne's ſucceſsful attempt completely to eſtabliſh Newton's ſyſtem of the univerſe, by his *Obſervations made on the Mountain Schehallien, for finding its attraction.* Sir John laid hold of this opportunity to give a perſpicuous and accurate relation of the ſeveral hypotheſes of the Ancients, with regard to the revolutions of the heavenly bodies, and of the noble diſcoveries with which Copernicus enriched the aſtronomical world. He then traces the progreſs of the grand principle of gravitation down to Sir Iſaac's illuſtrious confirmation of it; to which he adds a conciſe account of Meſſrs. Bouguer's and Condamine's experiment at Chimboraço, and of Mr. Maſkelyne's at Schehallien. If any doubts ſtill remained with reſpect to the truth of the Newtonian ſyſtem, they were now completely removed.

Sir John Pringle had reaſon to be peculiarly ſatisfied with the ſubject of his fourth diſcourſe; that ſubject being perfectly congenial to his diſpoſition and ſtudies. His own life had been much employed in pointing out the means which tended not only to cure, but to pre-

vent the diſeaſes of mankind; and it is probable, from his intimate friendſhip with captain Cook, that he might ſuggeſt to that ſagacious commander ſome of the rules which he followed, in order to preſerve the health of the crew of his ſhip, during his voyage round the world. Whether this was the caſe, or whether the method purſued by the captain to attain ſo ſalutary an end, was the reſult alone of his own reflections, the ſucceſs of it was aſtoniſhing; and this celebrated voyager ſeemed well entitled to every honour which could be beſtowed. To him the Society aſſigned their gold medal, but he was not preſent to receive the honour. He was gone out upon the voyage, from which he never returned. In this laſt voyage he continued equally ſucceſsful in maintaining the health of his men.

The learned preſident, in his fifth annual diſſertation, had an opportunity of diſplaying his knowledge in a way in which it had not hitherto appeared. The diſcourſe took its riſe from the adjudication of the prize medal to Mr. Mudge, then an eminent ſurgeon at Plymouth, on account of his valuable paper, containing *Directions for making the beſt Compoſition for the Metals of Reflecting Teleſcopes, together with a Deſcription of the Proceſs for Grinding, Poliſhing, and giving the Great Speculum the true Parabolic form.* Sir John hath accurately related a variety of particulars, concerning the invention of reflecting teleſcopes, the ſubſequent improvements of theſe inſtruments, and the ſtate in which Mr. Mudge found them, when he firſt ſet about working them to a greater perfection, till he had truly realized the expectation of Newton, who, above an hundred years ago, preſaged that the public would one day poſſeſs a parabolic ſpeculum, not accompliſhed by mathematical rules, but by mechanical devices.

Sir John Pringle's ſixth and laſt diſcourſe, to which he was led by the aſſignment of the gold medal to myſelf, on account of my paper intitled, *The Force of fired Gunpowder, and the Initial Velocity of Cannon Balls, determined by Experiments*, was on the theory of gunnery. Though Sir John had ſo long attended the army, this was probably a ſubject to which he had heretofore paid very little attention. We cannot however help admiring with what perſpicuity and judgment he hath ſtated the progreſs that was made, from time to time, in the knowledge of projectiles, and the ſcientific perfection to which it has been ſaid to be carried in my paper. As Sir John Pringle was not one of thoſe who delighted in war, and in the ſhedding of human blood, he was happy in being able to ſhew that even the ſtudy of artillery might be uſeful to mankind; and therefore this is a topic which he hath not forgotten to mention. Here ended our author's diſcourſes upon the delivery of Sir Godfrey Copley's medal, and his preſidency over the Royal Society at the ſame time, the delivering that medal into my hand being the laſt office he ever performed in that capacity; a ceremony which was attended by a greater number of the members, than had ever met together before upon any other occaſion. Had he been permitted to preſide longer in that chair, he would doubtleſs have found other occaſions of diſplaying his acquaintance with the hiſtory of philoſophy. But the opportunities which he had of ſignalizing himſelf in this reſpect were important in themſelves, happily varied, and ſufficient to gain him a ſolid and laſting reputation.

Several marks of literary diſtinction, as we have already ſeen, had been conferred upon Sir John Pringle, before he was raiſed to the preſident's chair. But after that event they were beſtowed upon him in great abundance, having been elected a member of almoſt all the literary ſocieties and inſtitutions in Europe. He was alſo, in 1774, appointed phyſician [illegible] king.

It was at rather a late period of [illegible] Pringle was choſen to be preſident [illegible] ciety, being then 65 years of age. [illegible] fore the great attention that was paid [illegible] rious and important duties of his offic[illegible] pains he took in the preparation of his [illegible] natural to expect that the burthen of his [illegible] tion ſhould grow heavy upon him in a courſe of time. This burthen, though not increaſed by any great addition to his life, for he was only 6 years preſident, was ſomewhat augmented by the accident of a fall in the area in the back part of his houſe, from which he received ſome hurt. From theſe circumſtances ſome perſons have affected to account for his reſigning the chair at the time when he did. But Sir John Pringle was naturally of a ſtrong and robuſt frame and conſtitution, and had a fair proſpect of being well able to diſcharge the duties of his ſituation for many years to come, had his ſpirits not been broken by the moſt cruel haraſſings and baitings in his office. His reſolution to quit the chair aroſe from the diſputes introduced into the Society, concerning the queſtion, whether pointed or blunted electrical conductors are the moſt efficacious in preſerving buildings from the pernicious effects of lightning, and from the cruel circumſtances attending thoſe diſputes. Theſe drove him from the chair. Such of thoſe circumſtances as were open and manifeſt to every one, were even of themſelves perhaps quite ſufficient to drive him to that reſolution. But there were yet others of a more private nature, which operated ſtill more powerfully and directly to produce that event; which may probably hereafter be laid before the public, when I ſhall give to them the hiſtory of the moſt material tranſactions of the Royal Society, eſpecially thoſe of the laſt 22 years, which I have from time to time compoſed and prepared with that view.

His intention of reſigning however, was diſagreeable to his friends, and the moſt diſtinguiſhed members of the Society, who were many of them perhaps ignorant of the true motive for it. Accordingly, they earneſtly ſolicited him to continue in the chair; but, his reſolution being fixed, he reſigned it at the anniverſary meeting in 1778, immediately on delivering the medal, at the concluſion of his ſpeech, as mentioned above.

Though Sir John Pringle thus quitted his particular relation to the Royal Society, and did not attend its meetings ſo conſtantly as he had formerly done, he ſtill retained his literary connections in general. His houſe continued to be the reſort of ingenious and philoſophical men, whether of his own country, or from abroad; and he was frequent in his viſits to his friends. He was held in particular eſteem by eminent and learned foreigners, none of whom came to England without waiting upon him, and paying him the greateſt reſpect. He treated them, in return, with diſtinguiſhed civility and regard. When a number of gentlemen met at

his

his table, foreigners were uſually a part of the company.

In 1780 Sir John ſpent the ſummer on a viſit to Edinburgh; as he did alſo that of 1781; where he was treated with the greateſt reſpect. In this laſt viſit he preſented to the Royal College of Phyſicians in that city, the reſult of many years labour, being ten folio volumes of *Medical and Phyſical Obſervations*, in manuſcript, on condition that they ſhould neither be publiſhed, nor lent out of the library of the college on any account whatever. He was at the ſame time preparing two other volumes, to be given to the univerſity, containing the formulas referred to in his annotations. He returned again to London, and continued for ſome time his uſual courſe of life, receiving and paying viſits to the moſt eminent literary men, but languiſhing and declining in his health and ſpirits, till the 18th of January 1782, when he died, in the 75th year of his age; the account of his death being every where received in a manner which ſhewed the high ſenſe that was entertained of his merit.

Sir John Pringle's eminent character as a practical phyſician, as well as a medical author, is ſo well known, and ſo univerſally acknowledged, that an enlargement upon it cannot be neceſſary. In the exerciſe of his profeſſion he was not rapacious; being ready, on various occaſions, to give his advice without pecuniary views. The turn of his mind led him chiefly to the love of ſcience, which he built on the firm baſis of fact. With regard to philoſophy in general, he was as averſe to theory, unſupported by experiments, as he was with reſpect to medicine in particular. Lord Bacon was his favourite author; and to the method of inveſtigation recommended by that great man, he ſteadily adhered. Such being his intellectual character, it will not be thought ſurpriſing that he had a diſlike to Plato. And to metaphyſical diſquiſitions he loſt all regard in the latter part of his life.

Sir John had no great fondneſs for poetry. He had not even any diſtinguiſhed reliſh for the immortal Shakeſpeare: at leaſt he ſeemed too highly ſenſible of the defects of that illuſtrious bard, to give him the proper degree of eſtimation. Sir John had not in his youth been neglectful of philological enquiries, nor did he deſert them in the laſt ſtages of his life, but cultivated even to the laſt a knowledge of the Greek language. He paid a great attention to the French language; and it is ſaid that he was fond of Voltaire's critical writings. Among all his other purſuits, he never forgot the ſtudy of the Engliſh language. This he regarded as a matter of ſo much conſequence, that he took uncommon pains with regard to the ſtyle of his compoſitions; and it cannot be denied, that he excelled in perſpicuity, correctneſs, and propriety of expreſſion. His ſix diſcourſes in particular, delivered at the annual meetings of the Royal Society, on occaſion of the prize medals, have been univerſally admired as elegant compoſitions, as well as critical and learned diſſertations. And this characteriſtic of them, ſeemed to increaſe and heighten, from year to year: a circumſtance which argues rather an improvement of his faculties, than any decline of them, and that even after the accident which it was pretended occaſioned his deſcent from the preſident's chair. So excellent indeed were theſe compoſitions eſteemed, that envy uſed to aſperſe his character with the imputation of borrowing the hand of another in thoſe learned diſcourſes. But how falſe ſuch aſperſion was, I, and I believe moſt of the other gentlemen who had the honour of receiving the annual medal from his hands, can fully teſtify. For myſelf in particular, I can witneſs for the laſt, and perhaps the beſt, that on the theory and improvements in gunnery, having been preſent or privy to his compoſition of every part of it.—Though our author was not fond of poetry, he had a great affection for the ſiſter art, muſic. Of this art he was not merely an admirer, but became ſo far a practitioner in it, as to be a performer on the violoncello, at a weekly concert given by a ſociety of gentlemen at Edinburgh. Beſides a cloſe application to medical and philoſophical ſcience, during the latter part of his life, he devoted much time to the ſtudy of divinity: this being with him a very favourite and intereſting object.

If, from the intellectual, we paſs on to the moral character of Sir John Pringle, we ſhall find that the ruling feature of it was integrity. By this principle he was uniformly actuated in the whole of his conduct and behaviour. He was equally diſtinguiſhed for his ſobriety. I and other perſons have heard him declare, that he had never once in his life been intoxicated with liquor. In his friendſhips, he was ardent and ſteady. The intimacies which were formed by him, in the early part of his life, continued unbroken to the deceaſe of the gentlemen with whom they were made; and were kept up by a regular correſpondence, and by all the good offices that lay in his power.

With regard to Sir John's external manner of deportment, he paid a very reſpectful attention to thoſe who were honoured with his friendſhip and eſteem, and to ſuch ſtrangers as came to him well recommended. Foreigners in particular had good reaſon to be ſatisfied with the uncommon pains which he took to ſhew them every mark of civility and regard. He had however at times ſomewhat of a dryneſs and reſerve in his behaviour, which had the appearance of coldneſs; and this was the caſe when he was not perfectly pleaſed with the perſons who were introduced to him, or who happened to be in his company. His ſenſe of integrity and dignity would not permit him to adopt that falſe and ſuperficial politeneſs, which treats all men alike, though ever ſo different in point of real eſtimation and merit, with the ſame ſhew of cordiality and kindneſs. He was above aſſuming the profeſſion, without the reality of reſpect.

PRISM, in Geometry, is a body, or ſolid, whoſe two ends are any plane figures which are parallel, equal, and ſimilar; and its ſides, connecting thoſe ends, are parallelograms.—Hence, every ſection parallel to the ends, is the ſame kind of equal and ſimilar figure as the ends themſelves are; and the Priſm may be conſidered as generated by the parallel motion of this plane figure.

Priſms take their ſeveral particular names from the figure of their ends. Thus, when the end is a triangle, it is a Triangular Priſm; when a ſquare, a Square Priſm; when a pentagon, a Pentagonal Priſm; when a hexagon, a Hexagonal Priſm; and ſo on. And hence the denomination Priſm compriſes alſo the cube and parallelopipedon, the former being a ſquare Priſm, and

the latter a rectangular one. And even a cylinder may be conſidered as a round Priſm, or one that has an infinite number of ſides. Alſo a Priſm is ſaid to be regular or irregular, according as the figure of its end is a regular or an irregular polygon.

The Axis of a Priſm, is the line conceived to be drawn lengthways through the middle of it, connecting the centre of one end with that of the other end.

Priſms, again, are either right or oblique.

A *Right* PRISM is that whoſe ſides, and its axis, are perpendicular to its ends; like an upright tower. And

An *Oblique* PRISM, is when the axis and ſides are oblique to the ends; ſo that, when ſet upon one end, it inclines on one hand, like an inclined tower.

The principal properties of Priſms, are,

1. That all Priſms are to one another in the ratio compounded of their baſes and heights.

2. Similar Priſms are to one another in the triplicate ratio of their like ſides.

3. A Priſm is triple of a pyramid of equal baſe and height; and the ſolid content of a Priſm is found by multiplying the baſe by the perpendicular height.

4. The upright ſurface of a right Priſm, is equal to a rectangle of the ſame height, and its breadth equal to the perimeter of the baſe or end. And therefore ſuch upright ſurface of a right Priſm, is found by multiplying the perimeter of the baſe by the perpendicular height. Alſo the upright ſurface of an oblique Priſm is found by computing thoſe of all its parallelogram ſides ſeparately, and adding them together.

And if to the upright ſurface be added the areas of the two ends, the ſum will be the whole ſurface of the Priſm.

PRISM, in Dioptrics, is a piece of glaſs in form of a triangular Priſm: which is much uſed in experiments concerning the nature of light and colours.

The uſe and phenomena of the Priſm ariſe from its ſides not being parallel to each other; from whence it ſeparates the rays of light in their paſſage through it, by coming through two ſides of one and the ſame angle.

The more general of theſe phenomena are enumerated and illuſtrated under the article Colour; which are ſufficient to prove, that colours do not either conſiſt in the contorſion of the globules of light, as Des Cartes imagined; nor in the obliquity of the pulſes of the etherial matter, as Hook fancied; nor in the conſtipation of light, and its greater or leſs concitation, as Dr. Barrow conjectured; but that they are original and unchangeable properties of light itſelf.

PRISMOID, is a ſolid, or body, ſomewhat reſembling a priſm, but that its ends are any diſſimilar parallel plane figures of the ſame number of ſides; the upright ſides being trapezoids.——If the ends of the Priſmoid be bounded by diſſimilar curves, it is ſometimes called a cylindroid.

PROBABILITY *of an Event*, in the Doctrine of Chances, is the ratio of the number of chances by which the event may happen, to the number by which it may both happen and fail. So that, if there be conſtituted a fraction, of which the numerator is the number of chances for the events happening, and the denominator the number for both happening and failing, that fraction will properly expreſs the value of the Probability of the event's happening. Thus, if an event have 3 chances for happening, and 2 for failing, the ſum of which being 5, the fraction $\frac{3}{5}$ will fitly repreſent the Probability of its happening, and may [illegible] meaſure of it. The ſame thing ma[illegible] lity of failing, which will li[illegible] fraction, whoſe numerator is [illegible] which it may fail, and its de[illegible] ber of chances both for its ha[illegible] Probability of the failing of [illegible] 2 chances to fail, and 3 to h[illegible] meaſured by the fraction $\frac{2}{5}$.

Hence, if there be added to[illegible] expreſs the Probability for both happening and failing, their ſum will always be equal to unity or 1; ſince the ſum of their numerators will be equal to their common denominator. And ſince it is a certainty that an event will either happen or fail, it follows that a certainty, which may be conſidered as an infinitely great degree of Probability, is fitly repreſented by unity. See Simpſon's or Demoivre's Doctrine of Chances; alſo Bernoulli's Ars Conjectandi; Monmort's Analyſe des Jeux de Haſard; or M. De Parcieu's Eſſais ſur les Probabilites de la Vie humaine. See alſo EXPECTATION, and GAMING.

PROBABILITY *of Life*. See EXPECTATION *of Life*, and LIFE-*Annuities*.

PROBLEM, in Geometry, is a propoſition in which ſome operation or conſtruction is required. As, to biſect a line, to make a triangle, to raiſe a perpendicular, to draw a circle through three points, &c.

A Problem, according to Wolfius, conſiſts of three parts: The propoſition, which expreſſes what is to be done; the reſolution, or ſolution, in which are orderly rehearſed the ſeveral ſteps of the proceſs or operation; and the demonſtration, in which it is ſhewn, that by doing the ſeveral things preſcribed in the reſolution, the thing required is obtained.

PROBLEM, in Algebra, is a queſtion or propoſition which requires ſome unknown truth to be inveſtigated or diſcovered; and the truth of the diſcovery demonſtrated.

PROBLEM, *Kepler's*. See KEPLER's *Problem*.

PROBLEM, *Determinate*, *Diophantine*, *Indeterminate*, *Limited*, *Linear*, *Local*, *Plane*, *Solid*, *Surſolid*, and *Unlimited*. See the adjectives.

Deliacal PROBLEM, in Geometry, is the doubling of a cube. This amounts to the ſame thing as the finding of two mean proportionals between two given lines; whence this alſo is called the Deliacal Problem. See DUPLICATION.

PROCLUS, an eminent philoſopher and mathematician among the later Platoniſts, was born at Conſtantinople in the year 410, of parents who were both able and willing to provide for his inſtruction in all the various branches of learning and knowledge. He was firſt ſent to Xanthus, a city of Lycia, to learn grammar: from thence to Alexandria, where he was under the beſt maſters in rhetoric, philoſophy, and mathematics: and from Alexandria he removed to Athens, where he attended the younger Plutarch, and Syrian, both of them celebrated philoſophers. He ſucceeded the latter in the

the government of the Platonic ſchool at Athens; where he died in 485, at 75 years of age.

Marinus of Naples, who was his ſucceſſor in the ſchool, wrote his life; the firſt perfect copy of which was publiſhed, with a Latin verſion and notes, by Fabricius at Hamburgh, 1700, in 4to; and afterwards [illegible] to his *Bibliotheca Latina*, 1703, in 8vo.

[illegible] wrote a great number of pieces, and upon [illegible] different ſubjects; as, commentaries on philoſophy, mathematics, and grammar; upon the whole works of Homer, Heſiod, and Plato's books of the republic; he wrote alſo on the conſtruction of the Aſtrolabe. Many of his pieces are loſt; ſome have been publiſhed; and a few remain ſtill in manuſcript only. Of the publiſhed, there are four very elegant hymns; one to the Sun, two to Venus, and one to the Muſes. There are commentaries upon ſeveral pieces of Plato; upon the four books of Ptolomy's work *de Judiciis Aſtrorum*; upon the firſt book of Euclid's Elements; and upon Heſiod's *Opera et Dies*. There are alſo works of Proclus upon philoſophical and aſtronomical ſubjects; particularly the piece *De Sphæra*, which was publiſhed, 1620, in 4to, by Bainbridge, the Savilian profeſſor of aſtronomy at Oxford. He wrote alſo 18 arguments againſt the Chriſtians, which are ſtill extant, and in which he attacks them upon the queſtion, whether the world be eternal? the affirmative of which he maintains.

The character of Proclus is the ſame as that of all the later Platoniſts, who it ſeems were not leſs enthuſiaſts and madmen, than the Chriſtians their contemporaries, whom they repreſented in this light. Proclus was not reckoned quite orthodox by his own order: he did not adhere ſo rigorouſly, as Julian and Porphyry, to the doctrines and principles of his maſter: "He had, ſays Cudworth, ſome peculiar fancies and whimſies of his own, and was indeed a confounder of the Platonic theology, and a mingler of much unintelligible ſtuff with it."

PROCYON, in Aſtronomy, a fixed ſtar, of the ſecond magnitude, in Canis Minor, or the Little Dog.

PRODUCING, in Geometry, denotes the continuing a line, or drawing it farther out, till it have an aſſigned length.

PRODUCT, in Arithmetic, or Algebra, is the factum of two numbers, or quantities, or the quantity ariſing from, or produced by, the multiplication of, two or more numbers &c together. Thus, 48 is the product of 6 multiplied by 8.—In multiplication, unity is in proportion to one factor, as the other factor is to the product. So 1 : 6 : : 8 : 48.

In Algebra, the product of ſimple quantities is expreſſed by joining the letters together like a word, and prefixing the product of the numeral coefficients: So the product of a and b is ab, of $3a$ and $4bc$ is $12abc$. But the product of compound factors or quantities is expreſſed by ſetting the ſign of multiplication between them, and binding each compound factor in a vinculum: ſo the product of $2a + 3b$ and $a - 4c$ is $\overline{2a + 3b} \times \overline{a - 4c}$, or $(2a + 3b) \times (a - 4c)$.

In geometry, a rectangle anſwers to a product, its length and breadth being the two factors; becauſe the numbers expreſſing the length and breadth being multiplied together, produce the content or area of the rectangle.

PROFILE, in Architecture, the figure or draught of a building, fortification, or the like; in which are expreſſed the ſeveral heights, widths, and thickneſſes, ſuch as they would appear, were the building cut down perpendicularly from the roof to the foundation. Whence the Profile is alſo called the Section, and ſometimes the Orthographical Section; and by Vitruvius the Sciography. In this ſenſe, Profile amounts to the ſame thing with Elevation; and ſo ſtands oppoſed to a Plan or Ichnography.

PROFILE is alſo uſed for the contour, or outline of a figure, building, member of architecture, or the like; as a baſe, a cornice, &c.

PROGRESSION, an orderly advancing or proceeding in the ſame manner, courſe, tenor, proportion, &c.

Progreſſion is either Arithmetical, or Geometrical.

Arithmetical PROGRESSION, is a ſeries of quantities proceeding by continued equal differences, either increaſing or decreaſing. Thus,

increaſing 1, 3, 5, 7, 9, &c, or
decreaſing 21, 18, 15, 12, 9, &c;

where the former progreſſion increaſes continually by the common difference 2, and the latter ſeries or Progreſſion decreaſes continually by the common difference 3.

1. And hence, to conſtruct an arithmetical Progreſſion, from any given firſt term, and with a given common difference; add the common difference to the firſt term, to give the 2d; to the 2d, to give the 3d; to the 3d, to give the 4th; and ſo on; when the ſeries is aſcending or increaſing: but ſubtract the common difference continually, when the ſeries is a deſcending one.

2. The chief property of an arithmetical Progreſſion, and which ariſes immediately from the nature of its conſtruction, is this; that the ſum of its extremes, or firſt and laſt terms, is equal to the ſum of every pair of intermediate terms that are equidiſtant from the extremes, or to the double of the middle term when there is an uneven number of the terms.

Thus,	1,	3,	5,	7,	9,	11,	13,
	13,	11,	9,	7,	5,	3,	1,
Sums	14	14	14	14	14	14	14,

where the ſum of every pair of terms is the ſame number 14.

Alſo, a,	$a + d$,	$a + 2d$,	$a + 3d$,	$a + 4d$,	
$a + 4d$,	$a + 3d$,	$a + 2d$,	$a + d$,	a	
ſums $2a + 4d$	$2a + 4d$	$2a + 4d$	$2a + 4d$	$2a + 4d$	

3. And hence it follows, that double the ſum of all the terms in the ſeries, is equal to the ſum of the two extremes multiplied by the number of the terms; and conſequently, that the ſingle ſum of all the terms of the ſeries, is equal to half the ſaid product. So the ſum of the 7 terms

1, 3, 5, 7, 9, 11, 13, is $\overline{1+13} \times \frac{7}{2} = 14 \times 7 = 49$. And the ſum of the five terms

$a,\ a+d,\ a+2d,\ a+3d,\ a+4d$, is $\overline{a+4d} \times \frac{5}{2}$.

4. Hence alſo, if the firſt term of the Progreſſion be 0, the ſum of the ſeries will be equal to half the product of the laſt term multiplied by the number of terms: i. e. the ſum of

$0+d+2d+3d+4d\cdots\cdots\overline{n-1}.d = \frac{1}{2}n.\overline{n-1}.d$,

where n is the number of terms, ſuppoſing 0 to be one of them. That is, in other words, the ſum of an arithmetical Progreſſion, whether finite or infinite, whoſe firſt term is 0, is to the ſum of as many times the greateſt term, in the ratio of 1 to 2.

5. In like manner, the ſum of the ſquares of the terms of ſuch a ſeries, beginning at 0, is to the ſum of as many terms each equal to the greateſt, in the ratio of 1 to 3. And

6. The ſum of the cubes of the terms of ſuch a ſeries, is to the ſum of as many times the greateſt term, in the ratio of 1 to 4.

7. And univerſally, if every term of ſuch a Progreſſion be raiſed to the m power, then the ſum of all thoſe powers will be to the ſum of as many terms equal to the greateſt, in the ratio of $m+1$ to 1. That is,

the ſum $0^m + d^m + 2d^m$ &c
is to $l^m + l^m + l^m$ &c

in the ratio of 1 to $m+1$.

8. A ſynopſis of all the [illegible] an arithmetical Progreſſion, [illegible] firſt and laſt term, the ſum o[illegible] terms, and the common [illegible] viz., if

a denote the leaſt term,
z the greateſt term,
d the common difference,
n the number of terms,
s the ſum of the ſeries;

then will each of theſe five quantities be expreſſed in terms of the others, as below:

$$a = z - \overline{n-1}.d = \frac{2s}{n} - z = \frac{s}{n} - \frac{n-1}{2}d = \sqrt{\left(\tfrac{1}{2}d + z\right)^2 - 2ds} + \tfrac{1}{2}d.$$

$$z = a + \overline{n-1}.d = \frac{2s}{n} - a = \frac{s}{n} + \frac{n-1}{2}d = \sqrt{\left(\tfrac{1}{2}d - a\right)^2 + 2ds} - \tfrac{1}{2}d.$$

$$d = \frac{z-a}{n-1} = \frac{s-na}{n-1}\cdot\frac{2}{n} = \frac{nz-s}{n-1}\cdot\frac{2}{n} = \frac{z+a}{2s-a-z}\cdot z-a.$$

$$n = \frac{z-a}{d} + 1 = \frac{2s}{a+z} = \frac{\frac{1}{2}d - a + \sqrt{\left(\frac{1}{2}d-a\right)^2 + 2ds}}{d} = \frac{\frac{1}{2}d + z - \sqrt{\left(\frac{1}{2}d+z\right)^2 - 2ds}}{d}.$$

$$s = \frac{a+z}{2}n = \frac{a+z}{2}\cdot\frac{z-a+d}{d} = \frac{2a+\overline{n-1}.d}{2}n = \frac{2z-\overline{n-1}.d}{2}n.$$

And moſt of theſe expreſſions will become much ſimpler if the firſt term be 0 inſtead of a.

Geometrical PROGRESSION, is a ſeries of quantities proceeding in the ſame continual ratio or proportion, either increaſing or decreaſing; or it is a ſeries of quantities that are continually proportional; or which increaſe by one common multiplier, or decreaſe by one common diviſor; which common multiplier or diviſor is called the common ratio. As,

increaſing, 1, 2, 4, 8, 16, &c,
decreaſing, 81, 27, 9, 3, 1, &c;

where the former progreſſion increaſes continually by the common multiplier 2, and the latter decreaſes by the common diviſor 3.

Or aſcending, $a,\ ra,\ r^2a,\ r^3a$, &c,

or deſcending, $a,\ \frac{a}{r},\ \frac{a}{r^2},\ \frac{a}{r^3}$, &c;

where the firſt term is a, and common ratio r.

1. Hence, the ſame principal properties obtain in a geometrical Progreſſion, as have been remarked of the arithmetical one, uſing only multiplication in the geometricals for addition in the arithmeticals, and diviſion in the former for ſubtraction in the latter. So that, to conſtruct a geometrical Progreſſion, from any given firſt term, and with a given common ratio; multiply the 1ſt term continually by the common ratio, for the reſt of the terms when the ſeries is an aſcending one; or divide continually by the common ratio, when it is a deſcending Progreſſion.

2. In every geometrical Progreſſion, the product of the extreme terms, is equal to the product of every pair of the intermediate terms that are equidiſtant from the extremes, and alſo equal to the ſquare of the middle term when there is a middle one, or an uneven number of the terms.

Thus,	1,	2,	4,	8,	16,
	16	8	4	2	1
prod.	16	16	16	16	16

Alſo	a,	ra,	r^2a,	r^3a,	r^4a,
	r^4a	r^3a	r^2a	ra	a
prod.	r^4a^2	r^4a^2	r^4a^2	r^4a^2	r^4a^2

3. The laſt term of a geometrical Progreſſion, is equal to the firſt term multiplied, or divided, by the ratio raiſed to the power whoſe exponent is leſs by 1 than the number of terms in the ſeries; ſo $z = ar^{n-1}$ when the ſeries is an aſcending one, or $z = \frac{a}{r^{n-1}}$, when it is a deſcending Progreſſion.

4. As the ſum of all the antecedents, or all the terms except the leaſt, is to the ſum of all the conſequents, or all the terms except the greateſt, ſo is 1 to r the ratio. For,

if $a + ra + r^2a + r^3a$ be all except the laſt, then $ra + r^2a + r^3a + r^4a$ are all except the firſt; where it is evident that the former is to the latter as 1 to r, or the former multiplied by r gives the latter. So that, z denoting the laſt term, a the firſt term, and r the ratio, alſo s the ſum of all the terms; then $s - z : s - a :: 1 : r$, or $s - a = s - z \cdot r$. And from this equation all the relations among the four quantities, a, z, r, s, are eaſily derived; ſuch as, $s = \frac{rz - a}{r - 1}$; viz, multiply the greateſt term by the ratio, ſubtract the leaſt term from the product, then the remainder divided by 1 leſs than the ratio, will give the ſum of the ſeries. And if the leaſt term a be 0, which happens when the deſcending Progreſſion is infinitely continued, then the ſum is barely $\frac{rz}{r-1}$. As in the infinite Progreſſion $1 + \frac{1}{2} + \frac{1}{4} + \frac{1}{8}$ &c, where $z = 1$, and $r = 2$, it is s or $\frac{rz}{r-1} = \frac{2}{2-1} = \frac{2}{1} = 2$.

5. The firſt or leaſt term of a geometrical Progreſſion, is to the ſum of all the terms, as the ratio minus 1, to the n power of the ratio minus 1; that is $a : s :: r - 1 : r^n - 1$.

Other relations among the five quantities a, z, r, n, s, where

a denotes the leaſt term,
z the greateſt term,
r the common ratio,
n the number of terms,
s the ſum of the Progreſſion,

are as below; viz,

$$a = \frac{z}{r^{n-1}} = zr - (r-1)s = \frac{r-1}{r^n-1}s.$$

$$z = ar^{n-1} = \frac{a + (r-1)s}{r} = \frac{r-1}{r^n-1}sr^{n-1}.$$

$$r = \frac{s-a}{s-z} = \sqrt[n-1]{\frac{z}{a}}.$$

$$n = \frac{\log.\frac{rz}{a}}{\log.r} = \frac{\log.\frac{a+(r-1)s}{a}}{\log.r} = \frac{\log.\frac{rz}{rz-(r-1)s}}{\log.r} = \frac{\log.\frac{s-az}{s-z\cdot a}}{\log.\frac{s-a}{s-z}}.$$

$$s = \frac{rz-a}{r-1} = \frac{r^n-1}{r-1}a = \frac{r^n-1}{r-1}\cdot\frac{z}{r^{n-1}} = \frac{\sqrt[n-1]{z^n} - \sqrt[n-1]{a^n}}{\sqrt[n-1]{z} - \sqrt[n-1]{a}}.$$

And the other values of a, z, and r are to be found from theſe equations, viz,

$$(s-z)^{n-1}z = (s-a)^{n-1}a,$$

$$r^n - \frac{s}{a}r = 1 - \frac{s}{a},$$

$$r^n - \frac{1}{s-z}r^{n-1} = \frac{z}{s-z}.$$

For other ſorts of Progreſſions, ſee SERIES.

PROJECTILE, or PROJECT, in Mechanics, is any body which, being put into a violent motion by an external force impreſſed upon it, is diſmiſſed from the agent, and left to purſue its courſe. Such as a ſtone thrown out of the hand or a ſling, an arrow from a bow, a ball from a gun, &c.

PROJECTILES, the ſcience of the motion, velocity, flight, range, &c, of a projectile put into violent motion by ſome external cauſe, as the force of gunpowder, &c. This is the foundation of gunnery, under which article may be found all that relates peculiarly to that branch.

All bodies, being indifferent as to motion or reſt, will neceſſarily continue the ſtate they are put into, except ſo far as they are hindered, and forced to change it by ſome new cauſe. Hence, a Projectile, put in motion, muſt continue eternally to move on in the ſame right line, and with the ſame uniform or conſtant velocity, were it to meet with no reſiſtance from the medium, nor had any force of gravity to encounter.

In the firſt caſe, the theory of Projectiles would be very ſimple indeed; for there would be nothing more to do, than to compute the ſpace paſſed over in a given time by a given conſtant velocity; or either of theſe, from the other two being given.

But by the conſtant action of gravity, the Projectile is continually deflected more and more from its right-lined courſe, and that with an accelerated velocity; which, being combined with its Projectile impulſe, cauſes the body to move in a curvilineal path, with a variable motion, which path is the curve of a parabola, as will be proved below; and the determination of the range, time of flight, angle of projection, and variable velocity, conſtitutes what is uſually meant by the doctrine of Projectiles, in the common acceptation of the word.

What is ſaid above however, is to be underſtood of Projectiles moving in a non-reſiſting medium; for when the reſiſtance of the air is alſo conſidered, which is enormouſly great, and which very much impedes the firſt Projectile velocity, the path deviates greatly from the parabola, and the determination of the circumſtances of its motion becomes one of the moſt complex and difficult problems in nature.

In the firſt place therefore it will be proper to conſider the common doctrine of Projectiles, or that on the parabolic theory, or as depending only on the nature of gravity and the Projectile motion, as abſtracted from the reſiſtance of the medium.

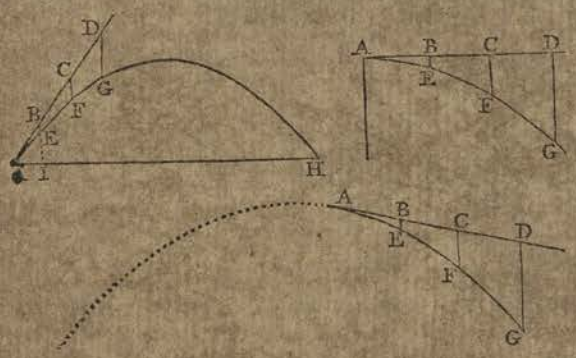
Little more than 200 years ago, philoſophers took the line deſcribed by a body projected horizontally, ſuch as a bullet out of a cannon, while the force of the powder greatly exceeded the weight of the bullet, to be a right line, after which they allowed it became a curve. Nicholas Tartaglia was the firſt who perceived the miſtake, maintaining that the path of the bullet was a curved line through the whole of its extent. But it was Galileo who firſt determined what particular curve it is that a Projectile deſcribes; ſhewing that the path of a bullet projected horizontally from an eminence, was a parabola; the vertex of which is the point where the bullet quits the cannon. And the ſame is proved generally, in the 2d ſection following, when the projection is made in any direction whatever, viz, that the curve

curve is always a parabola, ſuppoſing the body moves in a non-reſiſting medium.

The Laws of the Motion of PROJECTILES.

I. If a heavy body be projected perpendicularly, it will continue to aſcend or deſcend perpendicularly; becauſe both the projecting and the gravitating force are found in the ſame line of direction.

II. If a body be projected in free ſpace, either parallel to the horizon, or in any oblique direction; it will, by this motion, in conjunction with the action of gravity, deſcribe the curve line of a parabola.



For let the body be projected from A, in the direction AD, with any uniform velocity; then in any equal portions of time it would, by that impulſe alone, deſcribe the equal ſpaces AB, BC, CD, &c, in the line AD, if it were not drawn continually down below that line by the action of gravity. Draw BE, CF, DG, &c, in the direction of gravity, or perpendicular to the horizon; and take BE, CF, DG, &c, equal to the ſpaces through which the body would deſcend by its gravity in the ſame times in which it would uniformly paſs over the ſpaces AB, AC, AD, &c, by the Projectile motion. Then, ſince by theſe motions, the body is carried over the ſpace AB in the ſame time as the ſpace BE, and the ſpace AC in the ſame time as the ſpace CF, and the ſpace AD in the ſame time as the ſpace DG, &c; therefore, by the compoſition of motions, at the end of thoſe times the body will be found reſpectively in the points E, F, G, &c, and conſequently the real path of the Projectile will be the curve line AEFG &c. But the ſpaces AB, AC, AD, &c, being deſcribed by uniform motion, are as the times of deſcription; and the ſpaces BE, CF, DG, &c, deſcribed in the ſame times by the accelerating force of gravity, are as the ſquares of the times; conſequently the perpendicular deſcents are as the ſquares of the ſpaces in AD,

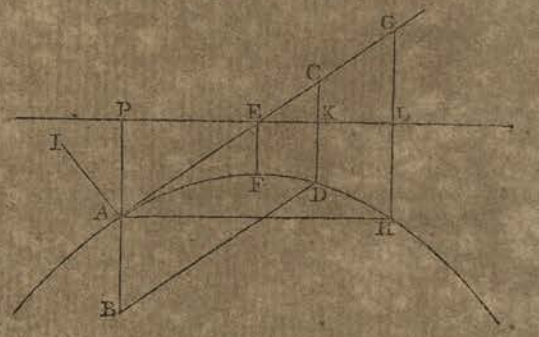
that is - - - - BE, CF, DG, &c, are reſpectively proportional to AB^2, AC^2, AD^2, &c, which is the ſame as the property of the parabola. Therefore the path of the Projectile is the parabolic line AEFG &c, to which AD is a tangent at the point A.

Hence, 1. The horizontal velocity of a Projectile is always the ſame conſtant quantity, in every point of the curve; becauſe the horizontal motion is in a conſtant ratio to the motion in AD, which is the uniform Projectile motion; viz, the conſtant horizontal velocity being to the Projectile velocity, as radius to the coſine of the angle DAH, or angle of elevation or depreſſion of the piece above or below the horizontal line AH.

2. The velocity of the Projectile in [illegible] the curve, or of its tangent, at any po[illegible] ſecant of its angle BAI of direction al[illegible] For the motion in the horizontal dire[illegible] conſtant, and AI being to AB as rad[illegible] of the angle A; therefore the motio[illegible] as the ſecant of the angle A.

3. The velocity in the direction DG of gravity, [illegible] perpendicular to the horizon, at any point G of the curve, is to the firſt uniform Projectile velocity at A, as 2GD to AD. For the times of deſcribing AD and DG being equal, and the velocity acquired by freely deſcending through DG being ſuch as would carry the body uniformly over twice DG in an equal time, and the ſpaces deſcribed with uniform motions being as the velocities, it follows that the ſpace AD is to the ſpace 2DG, as the Projectile velocity at A is to the perpendicular velocity at G.

III. The velocity in the direction of the curve, at any point of it, as A, is equal to that which is generated by gravity in freely deſcending through a ſpace which is equal to one-fourth of the parameter of the diameter to the parabola at that point.



Let PA or AB be the height due to the velocity of the Projectile at any point A, in the direction of the curve or tangent AC, or the velocity acquired by falling through that height; and complete the parallelogram ACDB. Then is CD = AB or AP the height due to the velocity in the curve at A; and CD is alſo the height due to the perpendicular velocity at D, which will therefore be equal to the former: but, by the laſt corollary, the velocity at A is to the perpendicular velocity at D, as AC to 2CD; and as theſe velocities are equal, therefore AC or BD is equal to 2CD or 2AB; and hence AB or AP is equal to $\frac{1}{4}$BD or $\frac{1}{4}$ of the parameter of the diameter AB by the nature of the parabola.

Hence, 1. If through the point P, the line PL be drawn perpendicular to AP; then the velocity in the curve at every point, will be equal to the velocity acquired by falling through the perpendicular diſtance

of

of the point from the ſaid line PL; that is, a body falling freely through

PA, acquires the velocity in the curve at A,
EF, - - - at F,
KD, - - - at D,
LH, - - - at H.

The reaſon of which is, that the line PL is what is called the Directrix of the parabola, the property of which is, that the perpendicular to it, from every point of the curve, is equal to one-fourth of the parameter of the diameter at that point, viz,

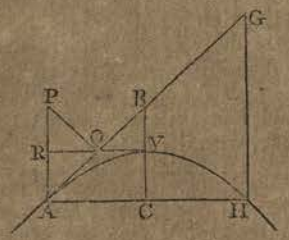
PA = ¼ the parameter of the diameter at A,
EF = - - - at F,
KD = - - - at D,
LH = - - - at H.

2. If a body, after falling through the height PA, which is equal to AB, and when it arrives at A if its courſe be changed, by reflection from a firm plane AI, or otherwiſe, into any direction AC, without altering the velocity; and if AC be taken equal to 2AP or 2AB, and the parallelogram be completed; the body will deſcribe the parabola paſſing through the point D.

3. Becauſe AC = 2AB or 2CD or 2AP, therefore $AC^2 = 2AP \cdot 2CD$ or $AP \cdot 4CD$; and becauſe all the perpendiculars EF, CD, GH are as AE^2, AC^2, AG^2; therefore alſo $AP \cdot 4EF = AE^2$, and $AP \cdot 4GH = AG^2$, &c; and becauſe the rectangle of the extremes is equal to the rectangle of the means, of four proportionals, therefore it is always,

AP : AE :: AE : 4EF,
and AP : AC :: AC : 4CD,
and AP : AG :: AG : 4GH,
and ſo on.

IV. Having given the Direction of a Projectile, and the Impetus or Altitude due to the firſt velocity; to determine the Greateſt Height to which it will riſe, and the Random or Horizontal Range.

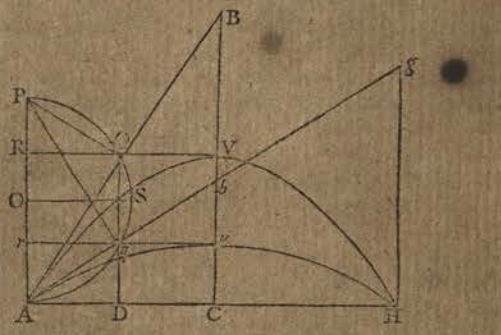


Let AP be the height due to the Projectile velocity at A, or the height which a body muſt fall to acquire the ſame velocity as the projectile has in the curve at A; alſo AG the direction, and AH the horizon. Upon AG let fall the perpendicular PQ, and on AP the perpendicular QR; ſo ſhall AR be equal to the greateſt altitude CV, and 4RQ equal to the horizontal range AH. Or, having drawn PQ perpendicular to AG, take AG = 4AQ, and draw GH perpendicular to AH; then AH is the range.

For by the laſt cor. - - - AP : AG :: AG : 4GH,
and by ſim. triangles, - - - AP : AG :: AQ : GH,
or AP : AG :: 4AQ : 4GH;
therefore AG = 4AQ; and, by ſimilar triangles, AH = 4RQ.

Alſo, if V be the vertex of the parabola, then AB or ¼AG = 2AQ, or AQ = QB; conſequently AR = BV which is = CV by the nature of the parabola.

Hence, 1. Becauſe the angle Q is a right angle, which is the angle in a ſemicircle, therefore if upon AP as a diameter a ſemicircle be deſcribed, it will paſs through the point Q.



2. If the Horizontal Range and the Projectile Velocity be given, the Direction of the piece ſo as to hit the object H will be thus eaſily found: Take AD = ¼AH, and draw DQ perpendicular to AH, meeting the ſemicircle deſcribed on the diameter AP in Q and *q*; then either AQ or A*q* will be the direction of the piece. And hence it appears, that there are two directions AB and A*b* which, with the ſame Projectile velocity, give the very ſame horizontal range AH; and theſe two directions make equal angles *q*AD and QAP with AH and AP, becauſe the arc PQ is equal to the arc A*q*.

3. Or if the Range AH and Direction AB be given; to find the Altitude and Velocity or Impetus: Take AD = ¼AH, and erect the perpendicular DQ meeting AB in Q; ſo ſhall DQ be equal to the greateſt altitude CV. Alſo erect AP perpendicular to AH, and QP to AQ; ſo ſhall AP be the height due to the velocity.

4. When the body is projected with the ſame velocity, but in different directions; the horizontal ranges AH will be as the ſines of double the angles of elevation. Or, which is the ſame thing, as the rectangle of the ſine and coſine of elevation. For AD or RQ, which is ¼AH, is the ſine of the arc AQ, which meaſures double the angle QAD of elevation.

And when the direction is the ſame, but the velocities different, the horizontal ranges are as the ſquare of the velocities, or as the height AP which is as the ſquare of the velocity; for the ſine AD or RQ, or ¼AH, is as the radius, or as the diameter AP

Therefore, when both are different, the ranges are in the compound ratio of the ſquares of the velocities, and the ſines of double the angles of elevation.

5. The greateſt range is when the angle of elevation is half a right angle, or 45°. For the double of 45 is 90°, which has the greateſt ſine. Or the radius OS, which is ½ of the range, is the greateſt ſine.

And hence the greateſt range, or that at an elevation of 45°, is juſt double the altitude AP which is due to

the velocity. Or equal to 4VC. And conſequently, in that caſe, C is the focus of the parabola, and AH its parameter.

And the ranges are equal at angles equally above and below 45°.

6. When the elevation is 15°, the double of which, or 30°, having its ſine equal to half the radius, conſequently its range will be equal to AP, or half the greateſt range at the elevation of 45°; that is, the range at 15° is equal to the impetus or height due to the projectile velocity.

7. The greateſt altitude CV, being equal to AR, is as the verſed ſine of double the angle of elevation, and alſo as AP or the ſquare of the velocity. Or as the ſquare of the ſine of elevation, and the ſquare of the velocity; for the ſquare of the ſine is as the verſed ſine of the double angle.

8. The time of flight of the projectile, which is equal to the time of a body falling freely through GH or 4CV, 4 times the altitude, is therefore as the ſquare root of the altitude, or as the projectile velocity and ſine of the elevation.

9. And hence may be deduced the following ſet of theorems, for finding all the circumſtances relating to projectiles on horizontal planes, having any two of them given. Thus, let

s, c, t = ſine, coſine, and tang. of elevation,

S, v = ſine and verſ. of double the elevation,

R the horizontal range, T the time of flight, V the projectile velocity, H the greateſt height of the projectile, $g = 16\frac{1}{12}$ feet, and a = the impetus or the altitude due to the velocity V. Then,

$$R = 2aS = 4asc = \frac{SV^2}{2g} = \frac{scV^2}{g} = \frac{gcT^2}{s} = \frac{gT^2}{t} = \frac{4H}{t}.$$

$$V = \sqrt{4ag} = \sqrt{\frac{2gR}{S}} = \sqrt{\frac{gR}{sc}} = \frac{gT}{s} = \frac{2\sqrt{gH}}{s}.$$

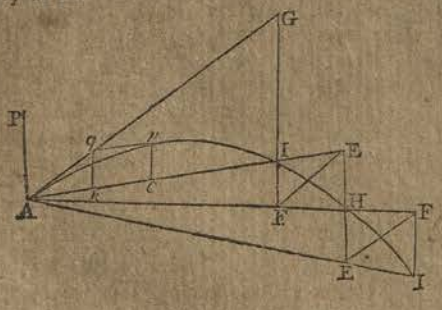
$$T = \frac{sV}{g} = 2s\sqrt{\frac{a}{g}} = \sqrt{\frac{tR}{g}} = \sqrt{\frac{sR}{gc}} = 2\sqrt{\frac{H}{g}}.$$

$$H = as^2 = \tfrac{1}{2}av = \tfrac{1}{4}tR = \frac{sR}{4c} = \frac{sV^2}{4g} = \frac{vV^2}{8g} = \frac{gT^2}{4}.$$

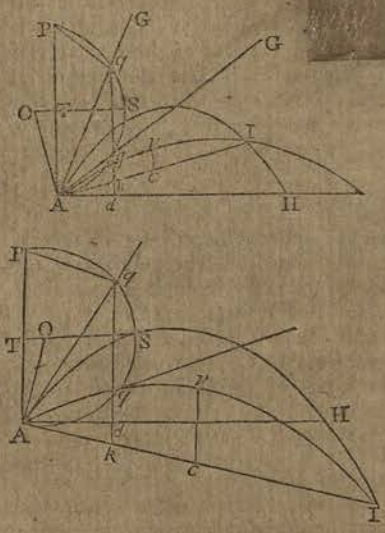
And from any of theſe, the angle of direction may be found.

V. To determine the Range on an oblique plane; having given the Impetus or the Velocity, and the Angle of Direction.

Let AE be the oblique plane, at a given angle above or below the horizontal plane AH; AG the direction of the piece; and AP the altitude due to the projectile velocity at A.



By the laſt prop. find the horizontal range AH to the given velocity and direction; draw HE perpendicular to AH meeting the oblique plane in E; draw EF parallel to the direction AG, and FI parallel to HE; ſo ſhall the projectile paſs through I, and the range on the oblique plane will be AI. This is evident from prob. 17 of the Parabola in my treatiſe of Conic Sections, where it is proved, that if AH, [illegible] lines terminated at the curve, and IF, H[illegible] the axis; then is EF parallel to the tan[illegible]



Hence, 1. If AO be drawn perpendicular to the plane AI, and AP be biſected by the perpendicular STO; then with the centre O deſcribing a circle through A and P, the ſame will alſo paſs through q, becauſe the angle GAI, formed by the tangent AG and AI, is equal to the angle APq, which will therefore ſtand upon the ſame arc Aq.

2. If there be given the Range and Velocity, or the Impetus, the Direction will then be eaſily found thus: Take $Ak = \frac{1}{4}AI$, draw kq perpendicular to AH, meeting the circle deſcribed with the radius AO in two points q and q; then Aq or Aq will be the direction of the piece. And hence it appears that there are two directions, which, with the ſame impetus, give the very ſame range AI, on the oblique plane. And theſe two directions make equal angles with AI and AP, the plane and the perpendicular, becauſe the arc Pq = the arc Aq. They alſo make equal angles with a line drawn from A through S, becauſe the arc Sq = the arc Sq.

3. Or, if there be given the Range AI, and the Direction Aq; to find the Velocity or Impetus. Take $Ak = \frac{1}{4}AI$, and erect kq perpendicular to AH meeting the line of direction in q; then draw qP making the angle AqP = the angle Akq; ſo ſhall AP be the impetus, or altitude due to the projectile velocity.

4. The range on an oblique plane, with a given elevation, is directly as the rectangle of the coſine of the direction of the piece above the horizon and the ſine of the direction above the oblique plane, and reciprocally as the ſquare of the coſine of the angle of the plane above or below the horizon.

For

For put s = fin. $\angle qAI$ or APq,
c = cof. $\angle qAH$ or fin. PAq,
C = cof. $\angle IAH$ or fin. Akd or Akq or AqP.
Then, in the tri. APq, - - - C : s :: AP : Aq,
and in the tri. Akq, - - - C : c :: Aq : Ak,
therefore by compof. - - - $C^2 : cs$ :: AP : $Ak = \frac{1}{4}AI$.

So that the oblique range $AI = \frac{cs}{C^2} \times 4AP$.

Hence the range is the greateft when Ak is the greateft, that is when kq touches the circle in the middle point S, and then the line of direction paffes through S, and bifects the angle formed by the oblique plane and the vertex. Alfo the ranges are equal at equal angles above and below this direction for the maximum.

5. The greateft height cv or kq of the projectile, above the plane, is equal to $\frac{s^2}{c^2} \times AP$. And therefore it is as the impetus and fquare of the fine of direction above the plane directly, and fquare of the cofine of the plane's inclination reciprocally.

For C (fin. AqP) : s (fin. APq) :: AP : Aq,
and C (fin. Akq) : s (fin. kAq) :: Aq : kq,
therefore by comp. $C^2 : s^2$ :: AP : kq.

6. The time of flight in the curve AvI is $= \frac{2s}{C}\sqrt{\frac{AP}{g}}$, where $g = 16\frac{1}{12}$ feet. And therefore it is as the velocity and fine of direction above the plane directly, and cofine of the plane's inclination reciprocally. For the time of defcribing the curve, is equal to the time of falling freely through GI or $4kq$ or $\frac{4s^2}{C^2} \times AP$. Therefore, the time being as the fquare root of the diftance, $\sqrt{g} : \frac{2s}{C}\sqrt{AP}$ :: $1'' : \frac{2s}{C}\sqrt{\frac{AP}{g}}$ the time of flight.

7. From the foregoing corollaries may be collected the following fet of theorems, relating to projects made on any given inclined planes, either above or below the horizontal plane. In which the letters denote as before, namely,

c = cof. of direction above the horizon,
C = cof. of inclination of the plane,
s = fin. of direction above the plane,
R the range on the oblique plane,
T the time of flight,
V the projectile velocity,
H the greateft height above the plane,
a the impetus, or alt. due to the velocity V,
$g = 16\frac{1}{12}$ feet. Then

$$R = \frac{cs}{C^2} \times 4a = \frac{cs}{C^2 g}V^2 = \frac{gc}{s}T^2 = \frac{4c}{s}H.$$

$$H = \frac{s^2}{C^2}a = \frac{s^2V^2}{4gC^2} = \frac{sR}{4c} = \frac{g}{4}T^2.$$

$$V = \sqrt{4ag} = C\sqrt{\frac{gR}{cs}} = \frac{gC}{s}T = \frac{2C}{s}\sqrt{gH}.$$

$$T = \frac{2s}{C}\sqrt{\frac{a}{g}} = \frac{sV}{gC} = \sqrt{\frac{sR}{gc}} = 2\sqrt{\frac{H}{g}}.$$

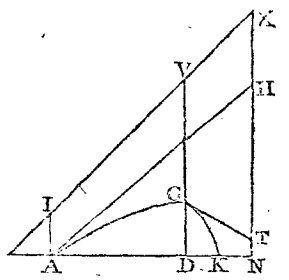
And from any of thefe, the angle of direction may be found.

Of the Path of PROJECTILES *as depending on the Refiftance of the Air.*

For a long time after Galileo, philofophers feemed to be fatisfied with the parabolic theory of Projectiles, deeming the effect of the air's refiftance on the path as of no confequence. In procefs of time, however, as the true philofophy began to dawn, they began to fufpect that the refiftance of the medium might have fome effect upon the Projectile curve, and they fet themfelves to confider this fubject with fome attention.

Huygens, fuppofing that the refiftance of the air was proportional to the velocity of the moving body, concluded that the line defcribed by it would be a kind of logarithmic curve.

But Newton, having clearly proved, that the refiftance to the body is not proportional to the velocity itfelf, but to the fquare of it, fhews, in his Principia, that the line a Projectile defcribes, approaches nearer to an hyperbola than a parabola. Schol. prop. 10, lib. 2. Thus, if AGK be a curve of



the hyperbolic kind, one of whofe afymptotes is NX, perpendicular to the horizon AK, and the other IX inclined to the fame, where VG is reciprocally as DN^n, whofe index is n: this curve will nearer repreſent the path of a Projectile thrown in the direction AH in the air, than a parabola. Newton indeed fays, that thefe hyperbolas are not accurately the curves that a Projectile makes in the air; for the true ones are curves which about the vertex are more diftant from the afymptotes, and in the parts remote from the axis approach nearer to the afymptotes than thefe hyperbolas; but that in practice thefe hyperbolas may be ufed inftead of thofe more compounded ones. And if a body be projected from A, in the right line AH, and AI be drawn parallel to the afymptote NX, and GT a tangent to the curve at the vertex: Then the denfity of the medium in A will be reciprocally as the tangent AH, and the body's velocity will be as $\sqrt{\frac{AH^2}{AI}}$, and the refiftance of the medium will be to gravity,

as AH to $\frac{2n^2+2n}{n+2} \times AI$.

M. John Bernoulli conftructed this curve by means of the quadrature of fome tranfcendental curves, at the

requeſt of Dr. Keil, who propoſed this problem to him in 1718. It was alſo reſolved by Dr. Taylor; and another ſolution of it may be found in Hermann's Phoronomia.

The commentators Le Sieur and Jacquier ſay, that the deſcription of the curve in which a Projectile moves, is ſo very perplexed, that it can ſcarcely be expected any deduction ſhould be made from it, either to philoſophical or mechanical purpoſes: vol. 2. pa. 118.

Dan. Bernoulli too proved, that the reſiſtance of the air has a very great effect on ſwift motions, ſuch as thoſe of cannon ſhot. He concludes from experiment, that a ball which aſcended only 7819 feet in the air, would have aſcended 58750 feet in vacuo, being near eight times as high. Comment. Acad. Petr. tom. 2.

M. Euler has farther inveſtigated the nature of this curve, and directed the calculation and uſe of a number of tables for the ſolution of all caſes that occur in gunnery, which may be accompliſhed with nearly as much expedition as by the common parabolic principles. Memoirs of the Academy of Berlin, for the year 1753.

But how raſh and erroneous the old opinion of the inconſiderable reſiſtance of the air is, will eaſily appear from the experiments of Mr. Robins, who has ſhewn that, in ſome caſes, this reſiſtance to a cannon ball, amounts to more than 20 times the weight of the ball; and I myſelf, having proſecuted this ſubject far beyond any former example, have ſometimes found this reſiſtance amount to near 100 times the weight of the ball, viz, when it moved with a velocity of 2000 feet per ſecond, which is a rate of almoſt 23 miles in a minute. What errors then may not be expected from an hypotheſis which neglects this force, as inconſiderable! Indeed it is eaſy to ſhew, that the path of ſuch Projectiles is neither a parabola nor nearly a parabola. For, by that theory, if the ball, in the inſtance laſt mentioned, flew in the curve of a parabola, its horizontal range, at 45° elevation, will be found to be almoſt 24 miles; whereas it often happens that the ball, with ſuch a velocity, ranges far ſhort of even one mile.

Indeed the falſeneſs of this hypotheſis almoſt appears at ſight, even in Projectiles flow enough to have their motion traced by the eye; for they are ſeen to deſcend through a curve manifeſtly ſhorter and more inclined to the horizon than that in which they aſcended, and the higheſt point of their flight, or the vertex of the curve, is much nearer to the place where they fall on the ground, than to that from whence they were at firſt diſcharged. Theſe things cannot for a moment be doubted of by any one, who in a proper ſituation views the flight of ſtones, arrows, or ſhells, thrown to any conſiderable diſtance.

Mr. Robins has not only detected the errors of the parabolic theory of gunnery, which takes no account of the reſiſtance of the air, but ſhews how to compute the real range of reſiſted bodies. But for the method which he propoſes, and the tables he has computed for this purpoſe, ſee his Tracts of Gunnery, pa. 183, &c, vol. 1; and alſo Euler's Commentary on the ſame, tranſlated by Mr. Hugh Brown, in 1777.

There is an odd circumſtance which often takes place in the motion of bodies projected with conſiderable force, which ſhews the great complication and difficulty of this ſubject; namely, that bullets in their flight are not only depreſſed beneath their original direction by the action of gravity, but are alſo frequently driven to the right or left of that direction by the action of ſome other force.

Now if it were true that bullets varied their direction by the action of gravity only, then it ought to happen that the errors in their flight to the right or left of the mark they were aimed at, ſhould increaſe in the proportion of the diſtance of the mark from the piece only. But this is contrary to all experience; the ſame piece which will carry its bullet within an inch of the intended mark, at 10 yards diſtance, cannot be relied on to 10 inches in 100 yards, much leſs to 30 in 300 yards.

And this inequality can only ariſe from the track of the bullet being incurvated ſideways as well as downwards; for by this means the diſtance between the incurvated line and the line of direction, will increaſe in a much greater ratio than that of the diſtance; theſe lines coinciding at the mouth of the piece, and afterwards ſeparating in the manner of a curve from its tangent, if the mouth of the piece be conſidered as the point of contact.

This is put beyond a doubt from the experiments made by Mr. Robins; who found alſo that the direction of the ſhot in the perpendicular line was not leſs uncertain, falling ſometimes 200 yards ſhort of what it did at other times, although there was no viſible cauſe of difference in making the experiment. And I myſelf have often experienced a difference of one-fifth or one-ſixth of the whole range, both in the deflection to the right or left, and alſo in the extent of the range, of cannon ſhot.

If it be aſked, what can be the cauſe of a motion ſo different from what has been hitherto ſuppoſed? It may be anſwered, that the deflection in queſtion muſt be owing to ſome power acting obliquely to the progreſſive motion of the body, which power can be no other than the reſiſtance of the air. And this reſiſtance may perhaps act obliquely to the progreſſive motion of the body, from inequalities in the reſiſted ſurface; but its general cauſe is doubtleſs a whirling motion acquired by the bullet about an axis, by its friction againſt the ſides of the piece; for by this motion of rotation, combined with the progreſſive motion, each part of the ball's ſurface will ſtrike the air in a direction very different from what it would do if there was no ſuch whirl; and the obliquity of the action of the air, ariſing from this cauſe, will be greater, according as the rotatory motion of the bullet is greater in proportion to its progreſſive motion. Tracts, vol. 1, p. 149, &c.

M. Euler, on the contrary, attributes this deflection of the ball to its figure, and very little to its rotation: for if the ball was perfectly round, though its centre of gravity did not coincide, the deflection from the axis of the cylinder, or line of direction ſideways, would be very inconſiderable. But when it is not round, it will generally

generally go to the right or left of its direction, and ſo much the more, as its range is greater. From his reaſoning on this ſubject he infers, that cannon ſhot, which are made of iron, and rounder and leſs ſuſceptible of a change of figure in paſſing along the cylinder than thoſe of lead, are more certain than muſket ſhot. True Principles of Gunnery inveſtigated, 1777, p. 304, &c.

PROJECTION, in Mechanics, the act of giving a projectile its motion.

If the direction of the force, by which the projectile is put in motion, be perpendicular to the horizon, the Projection is ſaid to be perpendicular; if parallel to the apparent horizon, it is ſaid to be an horizontal Projection; and if it make an oblique angle with the horizon, the Projection is oblique. In all caſes, the angle which the line of direction makes with the horizontal line, is called the angle of Elevation of the projectile, or of Depreſſion when the line of direction points below the horizontal line.

PROJECTION, in Perſpective, denotes the appearance or repreſentation of an object on the perſpective plane. So, the Projection of a point, is a point, where the optic ray paſſes from the objective point through the plane to the eye; or it is the point where the plane cuts the optic ray. — And hence it is eaſy to conceive what is meant by the projection of a line, a plane, or a ſolid.

PROJECTION *of the Sphere in Plano*, is a repreſentation of the ſeveral points or places of the ſurface of the ſphere, and of the circles deſcribed upon it, upon a tranſparent plane placed between the eye and the ſphere, or ſuch as they appear to the eye placed at a given diſtance. For the laws of this Projection, ſee PERSPECTIVE; the Projection of the ſphere being only a particular caſe of perſpective.

The chief uſe of the Projection of the ſphere, is in the conſtruction of planiſpheres, maps, and charts; which are ſaid to be of this or that Projection, according to the ſeveral ſituations of the eye, and the perſpective plane, with regard to the meridians, parallels, and other points or places to be repreſented.

The moſt uſual Projection of maps of the world, is that on the plane of the meridian, which exhibits a right ſphere; the firſt meridian being the horizon. The next is that on the plane of the equator, which has the pole in the centre, and the meridians the radii of a circle, &c; and this repreſents a parallel ſphere. See MAP.—The primitive circle is that great circle.

The Projection of the ſphere is uſually divided into Orthographic and Stereographic; to which may be added Gnomonic.

Orthographic PROJECTION, is that in which the ſurface of the ſphere is drawn upon a plane, cutting it in the middle; the eye being placed at an infinite diſtance vertically to one of the hemiſpheres. And

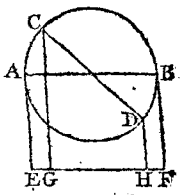
Stereographic PROJECTION of the ſphere, is that in which the ſurface and circles of the ſphere are drawn upon the plane of a great circle, the eye being in the pole of that circle.

Gnomonical PROJECTION *of the Sphere*, is that in which the ſurface of the ſphere is drawn upon a plane without ſide of it, commonly touching it, the eye being at the centre of the ſphere. See GNOMONICAL *Projection*.

Laws of the Orthographic Projection.

1. The rays coming from the eye, being at an infinite diſtance, and making the Projection, are parallel to each other, and perpendicular to the plane of Projection.

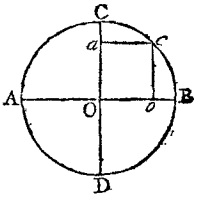
2. A right line perpendicular to the plane of Projection, is projected into a point, where that line meets the ſaid plane.



3. A right line, as AB, or CD, not perpendicular, but either parallel or oblique to the plane of the Projection, is projected into a right line, as EF or GH, and is always comprehended between the extreme perpendiculars AE and BF, or CG and DH.

4. The Projection of the right line AB is the greateſt, when AB is parallel to the plane of the Projection.

5. Hence it is evident, that a line parallel to the plane of the Projection, is projected into a right line equal to itſelf; but a line that is oblique to the plane of Projection, is projected into one that is leſs than itſelf.



6. A plane ſurface, as ACBD, perpendicular to the plane of the Projection, is projected into the right line, as AB, in which it cuts that plane. —Hence it is evident, that the circle ACBD perpendicular to the plane of Projection, paſſing through its centre, is projected into that diameter AB in which it cuts the plane of the Projection. Alſo any arch as C*c* is projected into O*o*, equal to *ca*, the right line of that arch; and the complemental arc *c*B is projected into *o*B, the verſed ſine of the ſame arc *c*B.

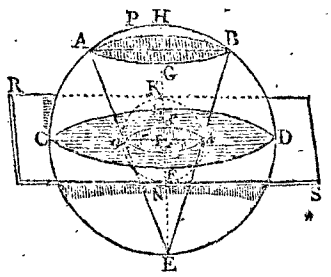
7. A circle parallel to the plane of the Projection, is projected into a circle equal to itſelf, having its centre the ſame with the centre of the Projection, and its radius equal to the coſine of its diſtance from the plane. And a circle oblique to the plane of the Projection, is projected into an ellipſis, whoſe greater axis is equal to the diameter of the circle, and its leſs axis equal to double the coſine of the obliquity of the circle, to a radius equal to half the greater axis.

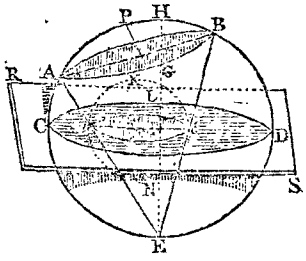
Properties of the Stereographic Projection.

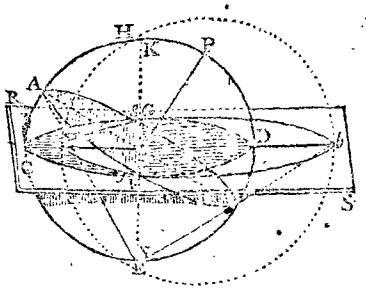
1. In this Projection a right circle, or one perpendicular to the plane of Projection, and paſſing through the eye, is projected into a line of half tangents.

2. The Projection of all other circles, not paſſing through the projecting point, whether parallel or oblique, are projected into circles.

Thus,

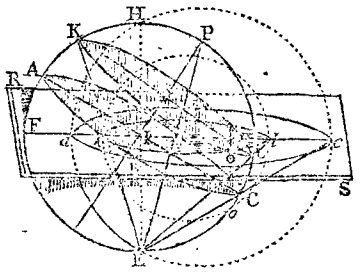






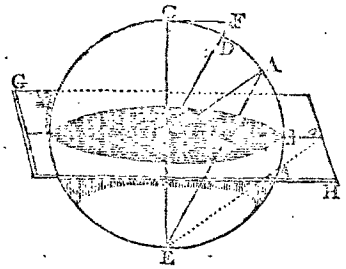
Thus, let ACEDB repreſent a ſphere, cut by a plane RS, paſſing through the centre I, perpendicular to the diameter EH, drawn from E the place of the eye; and let the ſection of the ſphere by the plane RS be the circle CFDL, whoſe poles are H and E. Suppoſe now AGB is a circle on the ſphere to be projected, whoſe pole moſt remote from the eye is P; and the viſual rays from the circle AGB meeting in E, form the cone AGBE, of which the triangle AEB is a ſection through the vertex E, and diameter of the baſe AB: then will the figure *agbf*, which is the Projection of the circle AGB, be itſelf a circle. Hence, the middle of the projected diameter is the centre of the projected circle, whether it be a great circle or a ſmall one: Alſo the poles and centres of all circles, parallel to the plane of Projection, fall in the centre of the Projection: And all oblique great circles cut the primitive circle in two points diametrically oppoſite.

2. The projected diameter of any circle ſubtends an angle at the eye equal to the diſtance of that circle from its neareſt pole, taken on the ſphere; and that angle is biſected by a right line joining the eye and that pole. Thus, let the plane RS cut the ſphere HFEG through



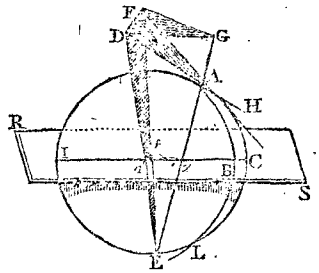
its centre I; and let ABC be any oblique great circle, whoſe diameter AC is projected into *ac*; and KOL any ſmall circle parallel to ABC, whoſe diameter KL is projected in *kl*. The diſtances of thoſe circles from their pole P, being the arcs AHP, KHP; and the angles *a*E*c*, *k*E*l*, are the angles at the eye, ſubtended by their projected diameters, *ac* and *kl*. Then is the angle *a*E*c* meaſured by the arc AHP, and the angle *k*E*l* meaſured by the arc KHP; and thoſe angles are biſected by EP.

3. Any point of a ſphere is projected at ſuch a diſtance from the centre of Projection, as is equal to the tangent of half the arc intercepted between that point and the pole oppoſite to the eye, the ſemidiameter of the ſphere being radius. Thus, let C*b*EB be a great circle of the ſphere, whoſe centre is *c*, GH the plane of Projection cutting the diameter of the ſphere in *b* and B; alſo E and C the poles of the ſection by that plane; and *a* the projection of A. Then *ca* is equal



the tangent of half the arc AC, as is evident by drawing CF = the tangent of half that arc, and joining *c*F.

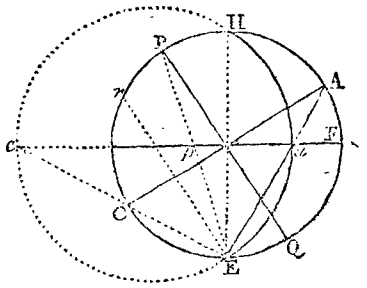
4. The angle made by two projected circles, is equal to the angle which theſe circles make on the ſphere. For let IACE and ABL be two circles on a ſphere



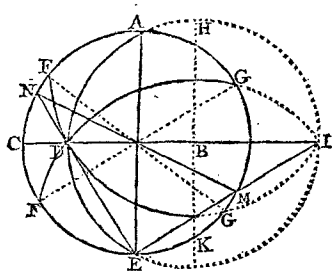
interſecting in A; E the projecting point; and RS the plane of Projection, in which the point A is projected in *a*, in the line IC, the diameter of the circle ACE. Alſo let DH and FA be tangents to the circles ACE and ABL. Then will the projected angle *daf* be equal to the ſpherical angle BAC.

5. The diſtance between the poles of the primitive circle and an oblique circle, is equal to the tangent of half the inclination of thoſe circles; and the diſtance of their centres, is equal to the tangent of their inclination; the ſemidiameter of the primitive being radius. For let AC be the diameter of a circle, whoſe poles are P and Q, and inclined to the plane of Projection in the angle AIF; and let *a*, *c*, *p* be the Projections of the points A, C, P; alſo let H*a*E be the projected oblique circle, whoſe centre is *q*. Now when the plane of Projection becomes the primitive circle, whoſe pole is I; then is I*p* = tangent of half the angle AIF, or of half

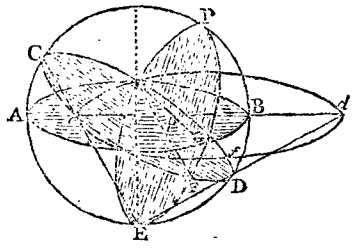
the arch AF; and Iq = tangent of AF, or of the angle FHa = AIF.



6. If through any given point in the primitive circle, an oblique circle be deſcribed; then the centres of all other oblique circles paſſing through that point, will be in a right line drawn through the centre of the firſt oblique circle, and perpendicular to a line paſſing through that centre, the given point, and the centre of the primitive circle. Thus, let GACE be the primitive circle, ADEI a great circle deſcribed through D, its centre being B. HK is a right line drawn through B perpendicular to a right line CI paſſing through D and B and the centre of the primitive circle. Then the centres of all other great circles, as FDG, paſſing through D, will fall in the line HK.

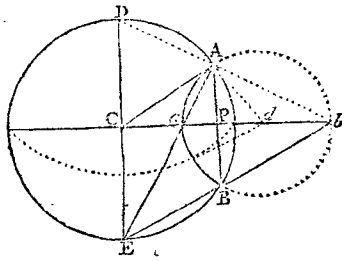


7. Equal arcs of any two great circles of the ſphere will be intercepted between two other circles drawn on the ſphere through the remoteſt poles of thoſe great circles. For let PBEA be a ſphere, on which AGB and CFD are two great circles, whoſe remoteſt poles are E and P; and through theſe poles let the great circle PBEC and the ſmall circle PGE be drawn, cutting the great circles AGB and CFD in the points B, G, D, F. Then are the intercepted arcs BG and DF equal to one another.



8. If lines be drawn from the projected pole of any great circle, cutting the peripherics of the projected circle and plane of Projection; the intercepted arcs of thoſe peripherics are equal; that is, the arc BG = *df*.

9. The radius of any leſſer circle, whoſe plane is perpendicular to that of the primitive circle, is equal to the tangent of that leſſer circle's diſtance from its pole; and the ſecant of that diſtance is equal to the diſtance of the centres of the primitive and leſſer circle. For let P be the pole, and AB the diameter of a leſſer circle, its plane being perpendicular to that of the primitive circle, whoſe centre is C: then *d* being the centre of the projected leſſer circle, *da* is equal to the tangent of the arc PA, and *d*C = the ſecant of PA. See STEREOGRAPHIC *Projection*.



Mercator's PROJECTION. See MERCATOR and CHART.

PROJECTION of Globes, &c. See GLOBE, &c.

Polar PROJECTION. See POLAR.

PROJECTION *of Shadows*. See SHADOW.

PROJECTION, or PROJECTURE, in Building, the outjetting or prominency which the mouldings and members have, beyond the plane or naked of the wall, column, &c.

Monſtrous PROJECTION. See ANAMORPHOSIS.

PROJECTIVE *Dialling*, a manner of drawing the hour lines, the furniture &c of dials, by a method of projection on any kind of ſurface whatever, without regard to the ſituation of thoſe ſurfaces, either as to declination, reclination, or inclination. See DIALLING.

PROLATE, or OBLONG *Spheroid*, is a ſpheroid produced by the revolution of a ſemiellipſis about its longer diameter; being longeſt in the direction of that axis, and reſembling an egg, or a lemon.

It is ſo called in oppoſition to the oblate or ſhort ſpheroid, which is formed by the rotation of a ſemiellipſis about its ſhorter axis; being therefore ſhorteſt in the direction of its axis, or flatted at the poles, and ſo reſembling an orange, or perhaps a turnip, according to the degree of flatneſs; and which is alſo the figure of the earth we inhabit, and perhaps of the planets alſo; having their equatorial diameter longer than the polar. See SPHEROID.

PROMONTORY, in Geography, is a rock or high point of land projecting out into the ſea. The extremity of which towards the ſea is uſually called a Cape, or Headland.

PROPORTION, in Arithmetic &c, the equality

or

or ſimilitude of ratios. As the four numbers 4, 8, 15, 30 are proportionals, or in proportion, becauſe the ratio of 4 to 8 is equal or ſimilar to the ratio of 15 to 30, both of them being the ſame as the ratio of 1 to 2.

Euclid, in the 5th definition of the 5th book, gives a general definition of four proportionals, or when, of four terms, the firſt has the ſame ratio to the 2d, as the 3d has to the 4th, viz, when any equimultiples whatever of the firſt and third being taken, and any equimultiples whatever of the 2d and 4th; if the multiple of the firſt be leſs than that of the 2d, the multiple of the 3d is alſo leſs than that of the 4th; or if the multiple of the firſt be equal to that of the 2d, the multiple of the 3d is alſo equal to that of the 4th; or if the multiple of the firſt be greater than that of the 2d, the multiple of the 3d is alſo greater than that of the 4th. And this definition is general for all kinds of magnitudes or quantities whatever, though a very obſcure one.

Alſo, in the 7th book, Euclid gives another definition of proportionals, viz, when the firſt is the ſame equimultiple of the 2d, as the 3d is of the 4th, or the ſame part or parts of it. But this definition appertains only to numbers and commenſurable quantities.

Proportion is often confounded with ratio; but they are quite different things. For, ratio is properly the relation of two magnitudes or quantities of one and the ſame kind; as the ratio of 4 to 8, or of 15 to 30, or of 1 to 2; and ſo implies or reſpects only two terms or things. But Proportion reſpects four terms or things, or two ratios which have each two terms. Though the middle term may be common to both ratios, and then the Proportion is expreſſed by three terms only, as 4, 8, 64, where 4 is to 8 as 8 to 64.

Proportion is alſo ſometimes confounded with progreſſion. In fact, the two often coincide; the difference between them only conſiſting in this, that progreſſion is a particular ſpecies of Proportion, being indeed a continued Proportion, or ſuch as has all the terms in the ſame ratio, viz, the 1ſt to the 2d, the 2d to the 3d, the 3d to the 4th, &c; as the terms 2, 4, 8, 16, &c; ſo that progreſſion is a ſeries or continuation of Proportions.

Proportion is either continual, or diſcrete or interrupted.

The Proportion is continual when every two adjacent terms have the ſame ratio, or when the conſequent of each ratio is the antecedent of the next following ratio, and ſo all the terms form a progreſſion; as 2, 4, 8, 16, &c; where 2 is to 4 as 4 to 8, and as 8 to 16, &c.

Diſcrete or interrupted Proportion, is when the conſequent of the firſt ratio is different from the antecedent of the 2d, &c; as 2, 4, and 3, 6.

Proportion is alſo either Direct or Inverſe.

Direct PROPORTION is when more requires more, or leſs requires leſs. As it will require more men to perform more work, or fewer men for leſs work, in the ſame time.

Inverſe or *Reciprocal* PROPORTION, is when more requires leſs, or leſs requires more. As it will require more men to perform the ſame work in leſs time, or fewer men in more time. Ex. If 6 men can perform a piece of work in 15 days, how many men can do the ſame in 10 days. Then,

reciprocally - as $\frac{1}{15}$ to $\frac{1}{10}$ ſo is 6 : 9 } the
or inverſely - as 10 to 15 ſo is 6 : 9 } anſwer.

Proportion, again, is diſtinguiſhed into Arithmetical, Geometrical, and Harmonical.

Arithmetical PROPORTION is the equality of two arithmetical ratios, or differences. As in the numbers 12, 9, 6; where the difference between 12 and 9, is the ſame as the difference between 9 and 6, viz 3.

And here the ſum of the extreme terms is equal to the ſum of the means, or to double the ſingle mean when there is but one. As $12 + 6 = 9 + 9 = 18$.

Geometrical PROPORTION is the equality between two geometrical ratios, or between the quotients of the terms. As in the three 9, 6, 4, where 9 is to 6 as 6 is to 4, thus denoted $9 : 6 :: 6 : 4$; for $\frac{9}{6} = \frac{6}{4}$, being each equal $\frac{3}{2}$ or $1\frac{1}{2}$.

And in this Proportion, the rectangle or product of the extreme terms, is equal to that of the two means, or the ſquare of the ſingle mean when there is but one. For $9 \times 4 = 6 \times 6 = 36$.

Harmonical PROPORTION, is when the firſt term is to the third, as the difference between the 1ſt and 2d is to the difference between the 2d and 3d; or in four terms when the 1ſt is to the 4th, as the difference between the 1ſt and 2d is to the difference between the 3d and 4th; or the reciprocals of an arithmetical Proportion are in harmonical Proportion. As 6, 4, 3; becauſe $6 : 3 :: 6 - 4 = 2 : 4 - 3 = 1$; or becauſe $\frac{1}{6}, \frac{1}{4}, \frac{1}{3}$ are in arithmetical Proportion, making $\frac{1}{6} + \frac{1}{3} = \frac{1}{4} + \frac{1}{4} = \frac{1}{2}$. Alſo the four 24, 16, 12, 9 are in harmonical Proportion, becauſe $24 : 9 :: 8 : 3$.

See PROPORTIONALS.

Compaſs of PROPORTION, a name by which the French, and ſome Engliſh authors, call the Sector.

Rule of PROPORTION, in Arithmetic, a rule by which a 4th term is found in Proportion to three given terms. And is popularly called the Golden Rule, or Rule of Three.

PROPORTIONAL, relating to Proportion. As, Proportional Compaſſes, Parts, Scales, Spirals, &c. See the ſeveral terms.

PROPORTIONAL *Compaſſes*, are compaſſes with two pair of oppoſite legs, like a St. Andrew's croſs, by which any ſpace is enlarged or diminiſhed in any proportion.

PROPORTIONAL *Part*, is a part of ſome number that is analogous to ſome other part or number; ſuch as the Proportional parts in the logarithms, and other tables.

PROPORTIONAL *Scales*, called alſo Logarithmic Scales, are the logarithms, or artificial numbers, placed on lines, for the eaſe and advantage of multiplying and dividing &c, by means of compaſſes, or of ſliding rulers. Theſe are in effect ſo many lines of numbers, as they are called by Gunter, but made ſingle, double, triple, or quadruple; beyond which they ſeldom go. See GUNTER'S *Scale*, SCALE, &c.

PROPORTIONAL *Spiral*. See SPIRAL.

PROPORTIONALITY, the quality of Proportionals. This term is uſed by Gregory St. Vincent, for the proportion that is between the exponents of four ratios.

PROPORTIONALS, are the terms of a proportion; conſiſting of two extremes, which are the firſt

and laſt terms of the ſet, and the means, which are the reſt of the terms. Theſe Proportionals may be either arithmeticals, geometricals, or harmonicals, and in any number above two, and alſo either continued or diſcontinued.

Pappus gives this beautiful and ſimple compariſon of the three kinds of Proportionals, arithmetical, geometrical, and harmonical, viz, a, b, c being the firſt, ſecond and third terms in any ſuch proportion, then

In the arithmeticals, $a \quad a$
in the geometricals, $a \cdot b$
in the harmonicals, $a : c$
$\Big\} :: a - b : b - c.$

See MEAN *Proportional.*

Continued Proportionals form what is called a progreſſion; for the properties of which ſee PROGRESSION.

I. *Properties of Arithmetical* PROPORTIONALS.

(For what reſpects Progreſſions and Mean Proportionals of all ſorts, ſee MEAN, and PROGRESSION.)

1. Four Arithmetical Proportionals, as 2, 3, 4, 5, are ſtill Proportionals when inverſely, 5, 4, 3, 2; or alternately, thus, - - 2, 4, 3, 5; or inverſely and alternately, thus - 5, 3, 4, 2.

2. If two Arithmeticals be added to the like terms of other two Arithmeticals, of the ſame difference or arithmetical ratio, the ſums will have double the ſame difference or arithmetical ratio.

So, to 3 and 5, whoſe difference is 2,
add 7 and 9, whoſe difference is alſo 2,
the ſums 10 and 14 have a double diff. viz 4.

And if to theſe ſums be added two other numbers alſo in the ſame difference, the next ſums will have a triple ratio or difference; and ſo on. Alſo, whatever be the ratios of the terms that are added, whether the ſame or different, the ſums of the terms will have ſuch arithmetical ratio as is compoſed of the ſums of the others that are added.

So 3 , 5, whoſe dif. is 2
and 7 , 10, whoſe dif. is 3
and 12 16, whoſe dif. is 4
make 22 , 31, whoſe dif. is 9.

On the contrary, if from two Arithmeticals be ſubtracted others, the difference will have ſuch arithmetical ratio as is equal to the differences of thoſe.

So from 12 and 16, whoſe dif. is 4
take 7 and 10, whoſe dif. is 3
leaves 5 and 6, whoſe dif. is 1

Alſo from 7 and 9, whoſe dif. is 2
take 3 and 5, whoſe dif. is 2
leaves 4 and 4, whoſe dif. is 0

3. Hence, if Arithmetical Proportionals be multiplied or divided by the ſame number, their difference, or arithmetical ratio, is alſo multiplied or divided by the ſame number.

II. *Properties of Geometrical Proportionals.*

The properties relating to mean Proportionals are given under the term MEAN *Proportional*; ſome are alſo given under the article Proportion; and ſome additional ones are as below:

1. *To find a 3d Proportional to two given numbers, or a 4th Proportional to three:* In the former caſe, multiply the 2d term by itſelf, and divide the product by the 1ſt: and in the latter caſe, multiply the 2d term by the 3d, and divide the product by the 1ſt.

So 2 : 6 :: 6 : 18, the 3d prop. to 2 and 6:
and 2 : 6 :: 5 : 15, the 4th prop. to 2, 6, and 5.

2. If the terms of any geometrical ratio be augmented or diminiſhed by any others in the ſame ratio, or proportion, the ſums or differences will ſtill be in the ſame ratio or proportion.

So if $a : b :: c : d$,
then is $a : b :: a \pm c : b \pm d :: c : d$.

And if the terms of a ratio, or proportion, be multiplied or divided by any one and the ſame number, the products and quotients will ſtill be in the ſame ratio, or proportion.

Thus, $a : b :: na : nb :: \frac{a}{n} : \frac{b}{n}$.

3. If a ſet of continued Proportionals be either augmented or diminiſhed by the ſame part or parts of themſelves, the ſums or differences will alſo be Proportionals.

Thus if a, b, c, d, &c be Propors.
then are $a \pm \frac{a}{n}$, $b \pm \frac{b}{n}$, $c \pm \frac{c}{n}$, &c alſo Propors.

where the common ratio is $1 \pm \frac{1}{n}$.

And if any ſingle quantity be either augmented or diminiſhed by ſome part of itſelf, and the reſult be alſo increaſed or diminiſhed by the ſame part of itſelf, and this third quantity treated in the ſame manner, and ſo on; then ſhall all theſe quantities be continued Proportionals. So, beginning with the quantity a, and taking always the nth part, then ſhall

a, $a \pm \frac{a}{n}$, $a \pm \frac{2a}{n} + \frac{a^2}{n^2}$, &c be Proportionals,

or a, $a \pm \frac{a}{n}$, $(a \pm \frac{a}{n})^2$, $(a \pm \frac{a}{n})^3$, &c Propors.

the common ratio being $1 \pm \frac{a}{n}$.

4. If one ſet of Proportionals be multiplied or divided by any other ſet of Proportionals, each term by each, the products or quotients will alſo be Proportionals.

Thus, if $a : na :: b : nb$,
and $c : mc :: d : md$;
then is $ac : mnac :: bd : mnbd$,
and $\frac{a}{c} : \frac{na}{mc} :: \frac{b}{d} : \frac{nb}{mb}$.

5. If there be ſeveral continued Proportionals, then whatever ratio the 1ſt has to the 2d, the 1ſt to the 3d

ſhall have the duplicate of the ratio, the 4th the triplicate of it, and ſo on.

So in a, na, n^2a, n^3a, &c, the ratio being n;
then $a : n^2a$, or 1 to n^2, the duplicate ratio,
and $a : n^3a$, or 1 to n^3, the triplicate ratio,
and ſo on.

6. In three continued Proportionals, the difference between the 1ſt and 2d term, is a mean Proportional between the 1ſt term and the ſecond difference of all the terms.

Thus, in the three Propor. a, na, n^2a;

Terms	1ſt difs.	2d dif.
n^2a.	$n^2a - na$	
na	$na - a$	$n^2a - 2na + a$,
a		

then $a : na - a :: na - a : n^2a - 2na + a$.

Or in the numbers 2, 6, 18;

18	12	8 the 2d difference;
6	4	
2		

then 2, 4, 8 are Proportionals.

7. When four quantities are in proportion, they are alſo in proportion by inverſion, compoſition, diviſion, &c; thus, a, na, b, nb being in proportion, viz,

1		$a : na :: b : nb$; then by
2. Inverſion		$na : a :: nb : b$;
3. Alternation		$a : b :: na : nb$;
4. Compoſition	$a + na : na :: b + nb : nb$;	
5. Converſion	$a + na : a :: b + nb : b$;	
6. Diviſion	$a - na : a :: b - nb : b$;	
	$a - na : na :: b - nb : nb$.	

III. *Properties of Harmonical Proportionals.*

1. If three or four numbers in Harmonical Proportion, be either multiplied or divided by any number, the products or quotients will alſo be Harmonical Proportionals.

Thus, 6, 3, 2 being harmon. Propor.
then 12, 6, 4 are alſo harmon. Propor.
and $\frac{6}{2}$, $\frac{3}{2}$, $\frac{2}{2}$ are alſo harmon. Propor.

2. In the three Harmonical Proportionals a, b, c, when any two of theſe are given, the 3d can be found from the definition of them, viz, that $a : c :: a - b : b - c$; for hence

$b = \frac{2ac}{a + c}$ the harmonical mean, and

$c = \frac{ab}{2a - b}$ the 3d harmon. to a and b.

3. And of the four Harmonicals, a, b, c, d, any three being given, the fourth can be found from the definition of them, viz, that $a : d :: a - b : c - d$; for thence the three b, c, d, will be thus found, viz,

$$b = \frac{2ad - ac}{d}; \quad c = \frac{2ad - bd}{a}; \quad d = \frac{ac}{2a - b}$$

4. If there be four numbers diſpoſed in order, as 2, 3, 4, 6, of which one extreme and the two middle terms are in Arithmetical Proportion, and the other extreme and the ſame middle terms are in Harmonical Proportion; then are the four terms in Geometrical Proportion: ſo here

the three 2, 3, 4 are arithmeticals,
and the three 3, 4, 6 are harmonicals,
then the four 2, 3, 4, 6 are geometricals.

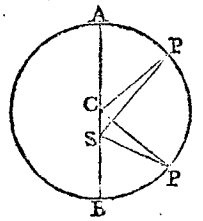
5. If between any two numbers, as 2 and 6, there be interpoſed an arithmetical mean 4, and alſo a harmonical mean 3, the four will then be geometricals, viz, $2 : 3 :: 4 : 6$.

6. Between the three kinds of proportion, there is this remarkable difference; viz, that from any given number there can be raiſed a continued arithmetical ſeries increaſing ad infinitum, but not decreaſing; while the harmonical can be decreaſed ad infinitum, but not increaſed; and the geometrical admits of both.

PROPOSITION, is either ſome truth advanced, and ſhewn to be ſuch by demonſtration; or ſome operation propoſed, and its ſolution ſhewn. In ſhort, it is ſomething propoſed either to be demonſtrated, or to be done or performed. The former is a theorem, and the latter is a problem.

PROSTHAPHERESIS, in Aſtronomy, the difference between the true and mean motion, or between the true and mean place, of a planet, or between the true and equated anomaly; called alſo Equation of the Orbit, or Equation of the Centre, or ſimply the Equation; and it is equal to the angle formed at the planet, and ſubtended by the excentricity of its orbit.

Thus, if S be the ſun, and P the place of a planet in its orbit APB, whoſe centre is C.



Then the mean anomaly is the ∠ ACP,
and the true anomaly the ∠ ASP,
the difference of which is the ∠ CPS,

which is the Proſthaphereſis; which is ſo called, becauſe it is ſometimes to be added to, and ſometimes to be ſubtracted from the mean motion, to give the true one; as is evident from the figure.

PROTRACTING, or PROTRACTION, in Surveying, the act of plotting or laying down the dimenſions taken in the field, by means of a Protractor, &c: Protracting makes one part of ſurveying.

PROTRACTING-*Pin*, a fine pointed pin, or needle, fitted into a handle, uſed to prick off degrees and minutes from the limb of the Protractor.

PROTRACTOR, a mathematical inſtrument, chiefly uſed in ſurveying, for laying down angles upon paper, &c.

The ſimpleſt, and moſt natural Protractor conſiſts of a ſemicircular limb ADB (fig. 7, pl. xix) commonly of metal, divided into 180°, and ſubtended by a diameter AB; in the middle of which is a ſmall notch C,

called the centre of the Protractor. And for the convenience of reckoning both ways, the degrees are numbered from the left hand towards the right, and from the right hand towards the left.

But this inſtrument is made much more commodious by transferring the diviſions from the circumference to the edge of a ruler, whoſe ſide EF is parallel to AB, which is eaſily done by laying a ruler on the centre C, and over the ſeveral diviſions on the ſemicircumference ADB, and marking the interſections of that ruler on the line EF: ſo that a ruler with theſe diviſions marked on one of its ſides as above, and returned down the two ends, and numbered both ways as in the circular Protractor, the fourth or blank ſide repreſenting the diameter of the circle, is both a more uſeful form than the circular Protractor, and better adapted for putting into a caſe.

To make any Angle with the Protractor.—Lay the diameter of the Protractor along the given line which is to be one ſide of the angle, and its centre at the given angular point; then make a mark oppoſite the given degree of the angle found on the limb of the inſtrument, and, removing the Protractor, by a plane ruler laid over that point and the centre, draw a line, which will form the angle ſought.

In the ſame way is any given angle meaſured, to find the number of degrees it contains.

This Protractor is alſo very uſeful in drawing one line perpendicular to another; which is readily done by laying the Protractor acroſs the given line, ſo that both its centre and the 90th degree on the oppoſite edge fall upon the line, alſo one of the edges paſſing over the given point, by which then let the perpendicular be drawn.

The Improved PROTRACTOR is an inſtrument much like the former, only furniſhed with a little more apparatus, by which an angle may be ſet off to a ſingle minute.

The chief addition is an index attached to the centre, about which it is moveable, ſo as to play freely and ſteadily over the limb. Beyond the limb the index is divided, on both edges, into 60 equal parts of the portions of circles, intercepted by two other right lines drawn from the centre, ſo that each makes an angle of one degree with lines drawn to the aſſumed points from the centre.

To ſet off an angle of any number of degrees and minutes with this Protractor, move the index, ſo that one of the lines drawn on the limb, from one of the forementioned points, may fall upon the number of degrees given; and prick off as many of the equal parts on the proper edge of the index as there are minutes given; then drawing a line from the centre to that point ſo pricked off, the required angle is thus formed with the given line or diameter of the Protractor.

PROVING *of Gunpowder.* See EPROUVETTE, and GUNPOWDER.

PSEUDO-STELLA, any kind of meteor or phenomenon, appearing in the heavens, and reſembling a ſtar.

PTOLEMAIC, or PTOLOMAIC, ſomething relating to Ptolomy; as the Ptolomaic Syſtem, the Ptolomaic Sphere, &c. See SYSTEM, SPHERE, &c.

PTOLEMY, or PTOLOMY, (CLAUDIUS), a very celebrated geographer, aſtronomer, and mathematician, among the Ancients, was born at Peluſium in Egypt, about the 70th year of the Chriſtian era; and died, it has been ſaid, in the 78th year of his age, and in the year of Chriſt 147. He taught aſtronomy at Alexandria in Egypt, where he made many aſtronomical obſervations, and compoſed his other works. It is certain that he flouriſhed in the reigns of Marcus Antoninus and Adrian: for it is noted in his Canon, that Antoninus Pius reigned 23 years, which ſhews that he himſelf ſurvived him; he alſo tells us in one place, that he made a great many obſervations upon the fixed ſtars at Alexandria, in the ſecond year of Antoninus Pius; and in another, that he obſerved an eclipſe of the moon, in the ninth year of Adrian; from which it is reaſonable to conclude that this aſtronomer's obſervations upon the heavens were many of them made between the year 125 and 140.

Ptolomy has always been reckoned the prince of aſtronomers among the Ancients, and in his works has left us an entire body of that ſcience. He has preſerved and tranſmitted to us the obſervations and principal diſcoveries of the Ancients, and at the ſame time augmented and enriched them with his own. He corrected Hipparchus's catalogue of the fixed ſtars; and formed tables, by which the motions of the ſun, moon, and planets, might be calculated and regulated. He was indeed the firſt who collected the ſcattered and detached obſervations of the Ancients, and digeſted them into a ſyſtem; which he ſet forth in his Μεγαλη Συνταξις, ſive *Magna Conſtructio*, divided into 13 books. He adopts and exhibits here the ancient ſyſtem of the world, which placed the earth in the centre of the univerſe; and this has been called from him, the Ptolomaic Syſtem, to diſtinguiſh it from thoſe of Copernicus and Tycho Brahe.

About the year 827 this work was tranſlated by the Arabians into their language, in which it was called *Almageſtum*, by order of one of their kings; and from Arabic into Latin, about 1230, by the encouragement of the emperor Frederic the 2d. There were alſo other verſions from the Arabic into Latin; and a manuſcript of one, done by Girardus Cremonenſis, who flouriſhed about the middle of the 14th century, Fabricius ſays, is ſtill extant in the library of All Souls College in Oxford. The Greek text of this work began to be read in Europe in the 15th century; and was firſt publiſhed by Simon Grynæus at Baſil, 1538, in folio, with the eleven books of commentaries by Theon, who flouriſhed at Alexandria in the reign of the elder Theodoſius. In 1541 it was reprinted at Baſil, with a Latin verſion by George Trapezond; and again at the ſame place in 1551, with the addition of other works of Ptolomy, and Latin verſions by Camerarius. We learn from Kepler, that this laſt edition was uſed by Tycho.

Of this principal work of the ancient aſtronomers, it may not be improper to give here a more particular account. In general, it may be obſerved, that the work is founded upon the hypotheſis of the earth's being at reſt in the centre of the univerſe, and that the heavenly bodies, the ſtars and planets, all move around it in ſolid orbs, whoſe motions are all directed by one, which Pto-

lomy called the *Primum Mobile*, or Firſt Mover, of which he diſcourſes at large. But, to be more particular, this great work is divided into 13 books.

In the firſt book, Ptolomy ſhews, that the earth is in the centre of thoſe orbs, and of the univerſe itſelf, as he underſtood it: he repreſents the earth as of a ſpherical figure, and but as a point in compariſon of the reſt of the heavenly bodies: he treats concerning the ſeveral circles of the earth, and their diſtances from the equator; as alſo of the right and oblique aſcenſion of the heavenly bodies in a right ſphere.

In the 2d book, he treats of the habitable parts of the earth; of the elevation of the pole in an oblique ſphere, and the various angles which the ſeveral circles make with the horizon, according to the different latitude of places; alſo of the phenomena of the heavenly bodies depending on the ſame.

In the 3d book, he treats of the quantity of the year, and of the unequal motion of the ſun through the zodiac: he here gives the method of computing the mean motion of the ſun, with tables of the ſame; and likewiſe treats of the inequality of days and nights.

In the 4th book, he treats of the lunar motions, and their various phenomena: he gives tables for finding the moon's mean motions, with her latitude and longitude: he diſcourſes largely concerning lunar epicycles; and by comparing the times of a great number of eclipſes, mentioned by Hipparchus, Calippus, and others, he has computed the places of the ſun and moon, according to their mean motions, from the firſt year of Nabonazar, king of Egypt, to his own time.

In the 5th book, he treats of the inſtrument called the Aſtrolabe: he treats alſo of the eccentricity of the lunar orbit, and the inequality of the moon's motion, according to her diſtance from the ſun: he alſo gives tables, and an univerſal canon for the inequality of the lunar motions: he then treats of the different aſpects or phaſes of the moon, and gives a computation of the diameter of the ſun and moon, with the magnitude of the ſun, moon and earth compared together; he ſtates alſo the different meaſures of the diſtance of the ſun and moon, according as they are determined by ancient mathematicians and philoſophers.

In the 6th book, he treats of the conjunctions and oppoſitions of the ſun & ☽ moon, with tables for computing the mean time when they happen; of the boundaries of ſolar and lunar eclipſes; of the tables and methods of computing the eclipſes of the ſun and moon, with many other particulars.

In the 7th book, he treats of the fixed ſtars; and ſhews the methods of deſcribing them, in their various conſtellations, on the ſurface of an artificial ſphere or globe: he rectifies the places of the ſtars to his own time, and ſhews how different thoſe places were then, from what they had been in the times of Timocharis, Hipparchus, Ariſtillus, Calippus, and others: he then lays down a catalogue of the ſtars in each of the northern conſtellations, with their latitude, longitude, and magnitudes.

In the 8th book, he gives a like catalogue of the ſtars in the conſtellations of the ſouthern hemiſphere, and in the 12 ſigns or conſtellations of the zodiac. This is the firſt catalogue of the ſtars now extant, and forms the moſt valuable part of Ptolomy's works. He then treats of the galaxy, or milky-way; alſo of the planetary aſpects, with the riſing and ſetting of the ſun, moon, and ſtars.

In the 9th book, he treats of the order of the ſun, moon, and planets, with the periodical revolutions of the five planets; then he gives tables of the mean motions, beginning with the theory of Mercury, and ſhewing its various phenomena with reſpect to the earth.

The 10th book begins with the theory of the planet Venus, treating of its greateſt diſtance from the ſun; of its epicycle, eccentricity, and periodical motions: it then treats of the ſame particulars in the planet Mars.

The 11th book treats of the ſame circumſtances in the theory of the planets Jupiter and Saturn. It alſo corrects all the planetary motions from obſervations made from the time of Nabonazar to his own.

The 12th book treats of the retrogreſſive motion of the ſeveral planets; giving alſo tables of their ſtations, and of the greateſt diſtances of Venus and Mercury from the ſun.

The 13th book treats of the ſeveral hypotheſes of the latitude of the five planets; of the greateſt latitude, or inclination of the orbits of the five planets, which are computed and diſpoſed in tables; of the riſing and ſetting of the planets, with tables of them. Then follows a concluſion or winding up of the whole work.

This great work of Ptolomy will always be valuable on account of the obſervations he gives of the places of the ſtars and planets in former times, and according to ancient philoſophers and aſtronomers that were then extant; but principally on account of the large and curious catalogue of the ſtars, which being compared with their places at preſent, we thence deduce the true quantity of their ſlow progreſſive motion according to the order of the ſigns, or of the preceſſion of the equinoxes.

Another great and important work of Ptolomy was, his *Geography*, in 7 books; in which, with his uſual ſagacity, he ſearches out and marks the ſituation of places according to their latitudes and longitudes; and he was the firſt that did ſo. Though this work muſt needs fall far ſhort of perfection, through the want of neceſſary obſervations, yet it is of conſiderable merit, and has been very uſeful to modern geographers. Cellarius indeed ſuſpects, and he was a very competent judge, that Ptolomy did not uſe all the care and application which the nature of his work required; and his reaſon is, that the author delivers himſelf with the ſame fluency and appearance of certainty, concerning things and places at the remoteſt diſtance, which it was impoſſible he could know any thing of, that he does concerning thoſe which lay the neareſt to him, and fall the moſt under his cognizance. Salmaſius had before made ſome remarks to the ſame purpoſe upon this work of Ptolomy. The Greek text of this work was firſt publiſhed by itſelf at Baſil in 1533, in 4to: afterward with a Latin verſion and notes by Gerard Mercator at Amſterdam, 1605; which laſt edition was reprinted at the ſame place, 1618, in folio, with neat geographical tables, by Bertius.

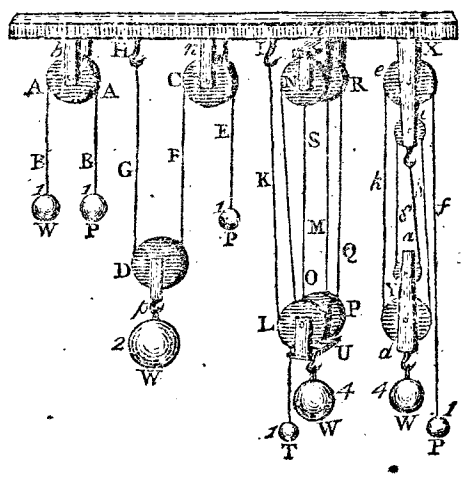
Other

Other works of Ptolomy, though leſs conſiderable than theſe two, are ſtill extant. As, *Libri quatuor de Judiciis Aſtrorum*, upon the firſt two books of which Cardan wrote a commentary.—*Fructus Librorum ſuorum*; a kind of ſupplement to the former work.—*Recenſio Chronologica Regum*: this, with another work of Ptolomy, *De Hypotheſibus Planetarum*, was publiſhed in 1620, 4to, by John Bainbridge, the Savilian profeſſor of Aſtronomy at Oxford: And Scaliger, Petavius, Dodwell, and the other chronological writers, have made great uſe of it.—*Apparentiæ Stellarum Inerrantium*: this was publiſhed at Paris by Petavius, with a Latin verſion, 1630, in folio; but from a mutilated copy, the defects of which have ſince been ſupplied from a perfect one, which Sir Henry Saville had communicated to archbiſhop Uſher, by Fabricius, in the 3d volume of his *Bibliotheca Græca*.—*Elementorum Harmonicorum libri tres*; publiſhed in Greek and Latin, with a commentary by Porphyry the philoſopher, by Dr. Wallis at Oxford, 1682, in 4to; and afterwards reprinted there, and inſerted in the 3d volume of Wallis's works, 1699, in folio.

Mabillon exhibits, in his *German Travels*, an effigy of Ptolomy looking at the ſtars through an optical tube; which effigy, he ſays, he found in a manuſcript of the 13th century, made by Conradus a monk. Hence ſome have fancied, that the uſe of the teleſcope was known to Conradus. But this is only matter of mere conjecture, there being no facts or teſtimonies, nor even probabilities, to ſupport ſuch an opinion.

It is rather likely that the tube was nothing more than a plain open one, employed to ſtrengthen and defend the eye-ſight, when looking at particular ſtars, by excluding adventitious rays from other ſtars and objects; a contrivance which no obſerver of the heavens can ever be ſuppoſed to have been without.

PULLEY, one of the five mechanical powers; conſiſting of a little wheel, being a circular piece of wood or metal, turning on an axis, and having a channel around it, in its edge or circumference, in which a cord ſlides and ſo raiſes up weights.



The Latins call it Trochlea; and the ſeamen, when fitted with a rope, a Tackle. An aſſemblage of ſeveral Pulleys is called a Syſtem of Pulleys, or Polyſpaſton: ſome of which are in a block or caſe, which is fixed; and others in a block which is moveable, and riſes with the weight. The wheel or rundle is called the Sheave or Shiver; the axis on which it turns, the Gudgeon; and the fixed piece of wood or iron, into which it is put, the Block.

Doctrine of the PULLEY.—1. If the equal weights P and W hang by the cord BB upon the pulley A, whoſe block *b* is fixed to the beam HI, they will counterpoiſe each other, juſt in the ſame manner as if the cord were cut in the middle, and its two ends hung upon the hooks fixed in the Pulley at A and A, equally diſtant from the centre.

Hence, a ſingle Pulley, if the lines of direction of the power and the weight be tangents to the periphery, neither aſſiſts nor impedes the power, but only changes its direction. The uſe of the Pulley therefore, is when the vertical direction of a power is to be changed into an horizontal one; or an aſcending direction into a deſcending one; &c. This is found a good proviſion for the ſafety of the workmen employed in drawing with the Pulley. And this change of direction by means of a Pulley has this farther advantage; that if any power can exert more force in one direction than another, we are hence enabled to employ it with its greateſt effect; as for the convenience of a horſe to draw in a horizontal direction, or ſuch like.

But the great uſe of the Pulley is in combining ſeveral of them together; thus forming what Vitruvius and others call Polyſpaſta; the advantages of which are, that the machine takes up but little room, is eaſily removed, and raiſes a very great weight with a moderate force.

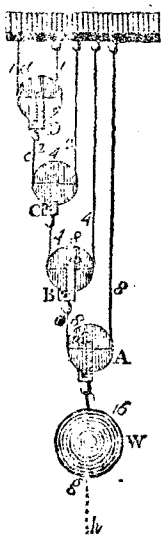
2. When a weight W hangs at the lower end of the moveable block *p* of the Pulley D, and the chord GF goes under the Pulley, it is plain that the part G of the cord bears one half of the weight W, and the part F the other half of it; for they bear the whole between them; therefore whatever holds the upper end of either rope, ſuſtains one half of the weight; and thus the power P, which draws the cord F by means of the cord E, paſſing over the fixed pulley C, will ſuſtain the weight W when its intenſity is only equal to the half of W; that is, in the caſe of one moveable Pulley, the power gained is as 2 to 1, or as the number of ropes G and F to the one rope E.

In like manner, in the caſe of two moveable Pulleys P and L, each of theſe alſo doubles the power, and produces a gain of 4 to 1, or as the number of the ropes Q, M, S, K, ſuſtaining the weight W, to the 1 rope O ſuſtaining the power T; that is, W is to T as 4 to 1. And ſo on, for any number of moveable Pulleys, viz, 3 ſuch Pulleys producing an increaſe of power as 6 to 1; 4 Pulleys, as 8 to 1; &c; each power adding 2 to the number. Alſo the effect is the ſame, when the Pulleys are diſpoſed as in the fixed block X, and the other two as in the moveable block Y; theſe in the lower block giving the ſame advantage to the power, when they riſe all together in one block with the weight.

But if the lower Pulleys do not riſe all together in one block with the weight, but act upon one another, having the weight only faſtened to the loweſt of them, the

force

force of the power is ſtill more increaſed, each power doubling the former numbers, the gain of power in this caſe proceeding in the geometrical progreſſion, 1, 2, 4, 8, 16, &c, according to the powers of 2; whereas in the former caſe, the gain was only in arithmetical progreſſion, increaſing by the addition of 2. Thus, a power whoſe intenſity is equal to 8lb applied at *a* will, by means of the lower Pulley A, ſuſtain 16lb; and a power equal to 4lb at *b*, by means of the Pulley, will ſuſtain the power of 8lb acting at *a*, and conſequently the weight of 16lb at W; alſo a third power equal to 2lb at *c*, by means of the Pulley C, will ſuſtain the power of 4lb at *b*; and a 4th power of 1lb at *d*, by means of the Pulley D, will ſuſtain the power 2 at *c*, and conſequently the power 4 at B, and the power 8 at A, and the weight 16 at W.

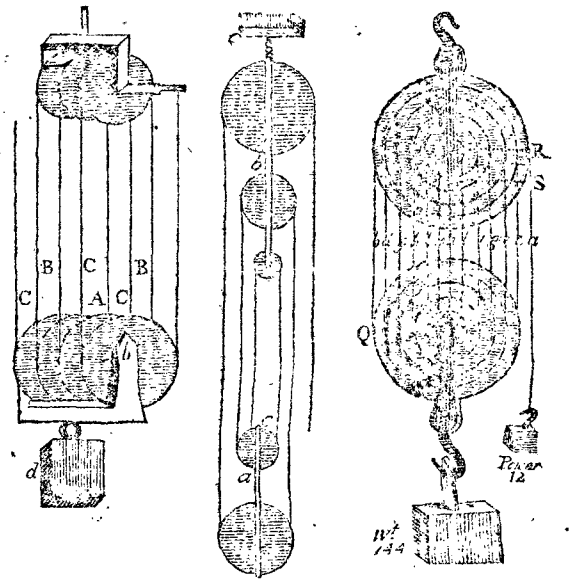


3. It is to be noted however, that, in whatever proportion the power is gained, in that very ſame proportion is the length of time increaſed to produce the ſame effect. For when a power moves a weight by means of ſeveral Pulleys, the ſpace paſſed over by the power is to the ſpace paſſed over by the weight, as the weight is to the power. Hence, the ſmaller a force is that ſuſtains a weight by means of Pulleys, the ſlower is the weight raiſed; ſo that what is ſaved or gained in force, is always ſpent or loſt in time: which is the general property of all the mechanical powers.

The uſual methods of arranging Pulleys in their blocks, may be reduced to two. The firſt conſiſts in placing them one by the ſide of another, upon the ſame pin; the other, in placing them directly under one another, upon ſeparate pins. Each of theſe methods however is liable to inconvenience; and Mr. Smeaton, to avoid the impediments to which theſe combinations are ſubject, propoſes to combine theſe two methods in one. See the Philoſ. Tranſ. vol. 47, pa. 494.

Some inſtances of ſuch combinations of Pulleys are exhibited in the following figures; beſide which, there are alſo other varieties of forms.

A very conſiderable improvement in the conſtruction of Pulleys has been made by Mr. James White, who has obtained a patent for his invention, and of which he gives the following deſcription. The laſt of the three following figures ſhews the machine, conſiſting of two Pulleys Q and R, one fixed and the other moveable. Each of theſe has ſix concentric grooves, capable of having a line put round them, and thus acting like as many different Pulleys, having diameters equal to thoſe of the grooves. Suppoſing then each of the grooves to be a diſtinct Pulley, and that all their diameters were equal, it is evident that if the weight 144 were to be raiſed by pulling at S till the Pulleys touch each other, the firſt Pulley muſt receive the length of line as many times as there are parts of the line hanging between it and the lower Pulley. In the preſent caſe, there are 12 lines, *b*, *d*, *f*, &c, hanging between the



two pulleys, formed by its revolution about the ſix upper lower grooves. Hence as much line muſt paſs over the uppermoſt Pulley as is equal to twelve times the diſtance of the two. But, from an inſpection of the figure, it is plain, that the ſecond Pulley cannot receive the full quantity of line by as much as is equal to the diſtance betwixt it and the firſt. In like manner, the third Pulley receives leſs than the firſt by as much as is the diſtance between the firſt and third; and ſo on to the laſt, which receives only one twelfth of the whole. For this receives its ſhare of line *n* from a fixed point in the upper frame, which gives it nothing; while all the others in the ſame frame receives the line partly by turning to meet it, and partly by the line coming to meet them.

Suppoſing now theſe Pulleys to be equal in ſize, and to move freely as the line determines them, it appears evident, from the nature of the ſyſtem, that the number of their revolutions, and conſequently their velocities, muſt be in proportion to the number of ſuſpending parts that are between the fixed point above mentioned and each Pulley reſpectively. Thus the outermoſt Pulley would go twelve times round in the time that the Pulley under which the part *n* of the line, if equal to it, would revolve only once; and the intermediate times and velocities would be a ſeries of arithmetical proportionals, of which, if the firſt number were 1, the laſt would always be equal to the whole number of terms. Since then the revolutions of equal and diſtinct Pulleys are meaſured by their velocities, and that it is poſſible to find any proportion of velocity, on a ſingle body running on a centre, viz, by finding proportionate diſtances from that centre; it follows, that if the diameters of certain grooves in the ſame ſubſtance be exactly adapted to the above ſeries (the line itſelf being ſuppoſed inelaſtic, and of no magnitude) the neceſſity of

of uſing ſeveral Pulleys in each frame will be obviated, and with that ſome of the inconveniencies to which the uſe of the Pulley is liable.

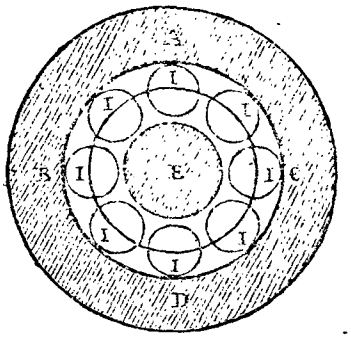
In the figure referred to, the coils of rope by which the weight is ſupported, are repreſented by the lines *a*, *b*, *c* &c; *a* is *the line of traction*, commonly called the fall, which paſſes over and under the proper grooves, until it is faſtened to the upper frame juſt above *n*. In practice, however, the grooves are not arithmetical proportions, nor can they be ſo; for the diameter of the rope employed muſt in all caſes be deducted from each term; without which the ſmaller grooves, to which the ſaid diameter bears a larger proportion than to the larger ones, will tend to riſe and fall faſter than they, and thus introduce worſe defects than thoſe which they were intended to obviate.

The principal advantage of this kind of Pulley is, that it deſtroys lateral friction, and that kind of ſhaking motion which is ſo inconvenient in the common Pulley. And leſt (ſays Mr. White) this circumſtance ſhould give the idea of weakneſs, I would obſerve, that to have pins for the pulleys to run on, is not the only nor perhaps the beſt method; but that I ſometimes uſe centres fixed to the Pulleys, and revolving on a very ſhort bearing in the ſide of the frame, by which ſtrength is increaſed, and friction very much diminiſhed; for to the laſt moment the motion of the Pulley is perfectly circular: and this very circumſtance is the cauſe of its not wearing out in the centre as ſoon as it would, aſſiſted by the ever increaſing irregularities of a gullied bearing. Theſe Pulleys, when well executed, apply to jacks and other machines of that nature with peculiar advantage, both as to the time of going and their own durability; and it is poſſible to produce a ſyſtem of Pulleys of this kind of ſix or eight parts only, and adapted to the pockets, which, by means of a ſkain of ſewing ſilk, or a clue of common thread, will raiſe upwards of an hundred weight.

As a ſyſtem of Pulleys has no great weight, and lies in a ſmall compaſs, it is eaſily carried about, and can be applied for raiſing weights in a great many caſes, where other engines cannot be uſed. But they are ſubject to a great deal of friction, on the following accounts; viz, 1ſt, becauſe the diameters of their axes bear a very conſiderable proportion to their own diameters; 2d, becauſe in working they are apt to rub againſt one another, or againſt the ſides of the block; 3dly, becauſe of the ſtiffneſs of the rope that goes over and under them. See Ferguſon's Mech. pa. 37, 4to.

But the friction of the Pulley is now reduced to nothing as it were, by the ingenious Mr. Garnett's patent friction rollers, which produce a great ſaving of labour and expence, as well as in the wear of the machine, both when applied to Pulleys and to the axles of wheel-carriages. His general principle is this; between the axle and nave, or centre pin and box, a hollow ſpace is left, to be filled up by ſolid equal rollers nearly touching each other. Theſe are furniſhed with axles inſerted into a circular ring at each end, by which their relative diſtances are preſerved; and they are kept parallel by means of wires faſtened to the rings between the rollers, and which are rivetted to them.

The above contrivance is exhibited in the annexed figure; where ABCD repreſents a piece of metal to be inſerted into the box or nave, of which E is the centre-pin or axle, and 1, 1, 1, &c, rollers of metal having



axes inſerted in the brazen circle which paſſes through their centres; and both circles being rivetted together by means of bolts paſſing between the rollers from one ſide of the nave to the other; and thus they are always kept ſeparate and parallel.

PUMP, in Hydraulics, a machine for raiſing water, and other fluids.

Pumps are probably of very ancient uſe. Vitruvius aſcribes the invention to Cteſebes of Athens, ſome ſay of Alexandria, about 120 years before Chriſt. They are now of various kinds. As the Sucking Pump, the Lifting Pump, the Forcing Pump, Ship Pumps, Chain Pumps, &c. By means of the lifting and forcing Pumps, water may be raiſed to any height, with a ſufficient power, and an adequate apparatus: but by the ſucking Pump the water may, by the general preſſure of the atmoſphere on the ſurface of the well, be raiſed only about 33 or 34 feet; though in practice it is ſeldom applied to the raiſing it much above 28; becauſe, from the variations obſerved in the barometer, it appears that the air may ſometimes be lighter than 33 feet of water; and whenever that happens, for want of the due counterpoiſe, this Pump may fail in its performance.

The Common Sucking PUMP.—This conſiſts of a pipe, of wood or metal, open at both ends, having a fixed valve in the lower part of it opening upwards, and a moveable valve or bucket by which the water is drawn or lifted up. This bucket is juſt the ſize of the bore of the Pump-pipe, in that part where it works, and leathered round ſo as to fit it very cloſe, that no air may paſs by the ſides of it; the valve hole being in the middle of the bucket. The bucket is commonly worked in the upper part of the barrel by a ſhort rod, and another fixed valve placed juſt below the deſcent of the bucket. Thus, (fig. 1, pl. 23), AB is the Pump-pipe, C the lower fixed valve, opening upwards, and D is the bucket, or moving valve, alſo opening upwards.

In working the Pump; draw up the bucket D, by means of the Pump rod, having any ſort of a handle fixed to it: this draws up the water that is above it, or if not, the air; in either caſe the water puſhes up the valve C, and enters to ſupply the void left between C and D, being puſhed up by the preſſure of the atmoſphere on the ſurface of the water in the well below. Next, the bucket D is puſhed down, which ſhuts the valve

valve C, and prevents the return of the water downwards, which opens the valve D, by which the water aſcends above it. And thus, by repeating the ſtrokes of the Pump-rod handle, the valves alternately open and ſhut, and the water is drawn up at every ſtroke, and runs out at the nozle or ſpout near the top.

The Lifting PUMP differs from the ſucking Pump only in the diſpoſition of its valves and the form of its piſton frame. This kind of Pump is repreſented in fig. 2, pl. 23; where the lower valve D is moveable, being worked up and down with the Pump rod, which lifts the water up, and ſo opens the upper valve C, which is fixed, and permits the water to iſſue through it, and run out at top. Then as the piſton D deſcends, the weight of the water above C ſhuts that valve C, and ſo prevents its return, till that valve be opened again by another lift of the piſton D. And ſo alternately.

The Forcing PUMP raiſes the water through the ſucker, or lower valve C (fig. 3, pl. 23), in the ſame manner as the ſucking Pump; but as the piſton or plunger D has no valve in it, the water cannot get above it when this is puſhed down again; inſtead of which, a ſide pipe is inſerted between C and D, having a fixed valve at E opening upwards, through which the water is forced out of the Pump by puſhing down the plunger D.

Obſervations on Pumps.—The force required to work a Pump, is equal to the weight of water raiſed at each ſtroke, or equal to the weight of water filling the cavity of the pipe, and its height equal to the length of the ſtroke made by the piſton. Hence if d denote the diameter of the pipe, and l the length of the ſtroke, both in inches; then is $\cdot 7854 d^2 l$ the content of the water raiſed at a ſtroke, in inches, or $\cdot 0028 d^2 l$ in ale gallons; and the weight of it is $\frac{d^2 l}{220}$ ounces or $\frac{d^2 l}{3520}$ lb. But if the handle of the pump be a lever which gains in the power of p to 1, the force of the hand to work the Pump will be only $\frac{d^2 l}{3520 p}$ lb, or, when p is 5 for inſtance, it will be $\frac{d^2 l}{17600}$ lb. And all theſe over and above the friction of the moving parts of the Pump.

To the forcing Pump is ſometimes adapted an air veſſel, which, being compreſſed by the water, by its elaſticity acts upon the water again, and forces it out to a great diſtance, and in a continued ſtream, inſtead of by jerks or jets. So, Mr. Newſham's water engine, for extinguiſhing fire, conſiſts of two forcing Pumps, which alternately drive water into a cloſe veſſel of air, by which means the air in it is condenſed, and compreſſes the water ſo ſtrongly, that it ruſhes out with great impetuoſity and force through a pipe that comes down into it, making a continued uniform ſtream.

By means of forcing Pumps, water may be raiſed to any height whatever above the level of a river or ſpring; and machines may be contrived to work theſe Pumps, either by a running ſtream, a fall of water, or by horſes.

Cteſebes's PUMP, acts both by ſuction and by preſſion. Thus, a braſs cylinder ABCD (fig. 5, pl. 23) furniſhed with a valve at L, is placed in the water. In this is fitted the piſton KM, made of green wood, which will not ſwell in the water, and is adjuſted to the aperture of the cylinder with a covering of leather, but without any valve. Another tube NH is fitted on at H, with a valve I opening upwards.—Now the piſton being raiſed, the water opens the valve L, and riſes into the cavity of the cylinder. When the piſton is depreſſed again, the valve I is opened, and the water is driven up through the tube HN.

This was the Pump uſed among the Ancients, and that from which both the others have been deduced. Sir Samuel Morland has endeavoured to increaſe its force by leſſening the friction; which he has done to good effect, ſo as to make it work with very little.

There are various kinds of Pumps uſed in ſhips, for throwing the water out of the hold, and upon other occaſions, as the Chain Pump, &c.

Air-PUMP, in Pneumatics, is a machine, by means of which the air is emptied out of veſſels, and a kind of vacuum produced in them. For the particulars of which, ſee AIR-*Pump*.

PUNCHEON, a meaſure for liquids, containing $\frac{1}{3}$ of a tun, or a hogſhead and $\frac{1}{2}$, or 84 gallons.

PUNCHINS, or PUNCHIONS, in Building, ſhort pieces of timber placed to ſupport ſome conſiderable weight.

PUNCTATED *Hyperbola*, in the higher geometry, an hyperbola whoſe conjugate oval is infinitely ſmall, that is, a point.

PUNCTUM *ex Comparatione*, is either focus, in the ellipſe or hyperbola; ſo called by Apollonius, becauſe the rectangle under two abſciſſes made at the focus, is equal to one fourth part of what he calls the figure, which is the ſquare of the conjugate axis, or the rectangle under the tranſverſe and the parameter.

PURBACH (GEORGE), a very eminent mathematician and aſtronomer, was born at Purbach, a town upon the confines of Bavaria and Auſtria, in 1423, and educated at Vienna. He afterwards viſited the moſt celebrated univerſities in Germany, France, and Italy; and found a particular friend and patron in cardinal Cuſa at Rome. Returning to Vienna, he was appointed mathematical profeſſor, in which office he continued till his death, which happened in 1461, in the 39th year of his age only, to the great loſs of the learned world.

Purbach compoſed a great number of pieces, upon mathematical and aſtronomical ſubjects; and his fame brought many ſtudents to Vienna, and among them, the celebrated Regiomontanus, between whom and Purbach there ſubſiſted the ſtricteſt friendſhip and union of ſtudies till the death of the latter. Theſe two laboured together to improve every branch of learning, by all the means in their power, though aſtronomy ſeems to have been the favourite of both; and had not the immature death of Purbach prevented his further purſuits, there is no doubt but that, by their joint induſtry, aſtronomy would have been carried to very great perfection. That this is not merely ſurmiſe, may be learnt from thoſe improvements which Purbach actually did make, to render the ſtudy of it more eaſy and practicable. His firſt eſſay was, to amend the Latin tranſlation of Ptolomy's Almageſt, which had been made from the Arabic verſion: this he did, not by the help of the Greek text, for he was unacquainted with that language, but by drawing the moſt probable conjectures from a ſtrict attention to the ſenſe of the author.

He

He then proceeded to other works, and among them, he wrote a tract, which he entitled, *An Introduction to Arithmetic*; then a treatise on *Gnomonics*, or *Dialling*, with tables suited to the difference of climates or latitudes; likewise a small tract concerning the *Altitudes of the Sun*, with a table; also, *Astrolabic Canons*, with a table of the parallels, proportioned to every degree of the equinoctial.

After this, he constructed Solid Spheres, or Celestial Globes, and composed a new table of fixed stars, adding the longitude by which every star, since the time of Ptolomy, had increased. He likewise invented various other instruments, among which was the Gnomon, or Geometrical Square, with canons and a table for the use of it.

He not only collected the various tables of the Primum Mobile, but added new ones. He made very great improvements in Trigonometry, and by introducing the table of Sines, by a decimal division of the radius, he quite changed the appearance of that science: he supposed the radius to be divided into 600000 equal parts, and computed the sines of the arcs, for every ten minutes, in such equal parts of the radius, by the decimal notation, instead of the duodecimal one delivered by the Greeks, and preserved even by the Arabians till our author's time; a project which was completed by his friend Regiomontanus, who computed the sines to every minute of the quadrant, in 10000000th parts of the radius.

Having prepared the tables of the fixed stars, he next undertook to reform those of the planets, and constructed some entirely new ones. Having finished his tables, he wrote a kind of Perpetual Almanac, but chiefly for the moon, answering to the periods of Meton and Calippus; also an Almanac for the Planets, or, as Regiomontanus afterwards called it, an Ephemeris, for many years. But observing there were some planets in the heavens at a great distance from the places where they were described to be in the tables, particularly the sun and moon (the eclipses of which were observed frequently to happen very different from the times predicted), he applied himself to construct new tables, particularly adapted to eclipses; which were long after famous for their exactness. To the same time may be referred his finishing that celebrated work, entitled, *A New Theory of the Planets*, which Regiomontanus afterwards published the first of all the works executed at his new printing-house.

PURE *Hyperbola*, is an Hyperbola without any oval, node, cusp, or conjugate point; which happens through the impossibility of two of its roots.

PURE *Mathematics*, *Proposition*, *Quadratics*, &c. See the several articles.

PURLINES, in Architecture, those pieces of timber that lie across the rafters on the inside, to keep them from sinking in the middle of their length.

PYRAMID, a solid having any plane figure for its base, and its sides triangles whose vertices all meet in a point at the top, called the vertex of the pyramid; the base of each triangle being the sides of the plane base of the Pyramid.—The number of triangles is equal to the number of the sides of the base; and a cone is a round Pyramid, or one having an infinite number of sides.—The Pyramid is also denominated from its base, being triangular when the base is a triangle, quadrangular when a quadrangle, &c.

The *axis* of the Pyramid, is the line drawn from the vertex to the centre of the base. When this axis is perpendicular to the base, the Pyramid is said to be a *right* one; otherwise it is *oblique*.

1. A Pyramid may be conceived to be generated by a line moved about the vertex, and so carried round the perimeter of the base.

2. All Pyramids having equal bases and altitudes, are equal to one another: though the figures of their bases should even be different.

3. Every Pyramid is equal to one-third of the circumscribed prism, or a prism of the same base and altitude; and therefore the solid content of the Pyramid is found by multiplying the base by the perpendicular altitude, and taking $\frac{1}{3}$ of the product.

4. The upright surface of a Pyramid, is found by adding together the areas of all the triangles which form that surface.

5. If a Pyramid be cut by a plane parallel to the base, the section will be a plane figure similar to the base; and these two figures will be in proportion to each other as the squares of their distances from the vertex of the Pyramid.

6. The centre of gravity of a Pyramid is distant from the vertex $\frac{3}{4}$ of the axis.

Frustum of a PYRAMID, is the part left at the bottom when the top is cut off by a plane parallel to the base.

The solid content of the Frustum of a Pyramid is found, by first adding into one sum the areas of the two ends and the mean proportional between them, the 3d part of which sum is a medium section, or is the base of an equal prism of the same altitude; and therefore this medium area or section multiplied by the altitude gives the solid content. So, if A denote the area of one end, a the area of the other end, and b the height; then $\frac{1}{3}(A + a + \sqrt{Aa})$ is the medium area or section, and $\frac{1}{3}(A + a + \sqrt{Aa}) \times b$ is the solid content.

PYRAMIDS *of Egypt*, are very numerous, counting both great and small; but the most remarkable are the three Pyramids of Memphis, or, as they are now called, of Gheisa or Gize. They are square Pyramids, and the dimensions of the greatest of them, are 700 feet on each side of the base, and the oblique height or slant side the same; its base covers, or stands upon, nearly 11 acres of ground. It is thought by some that these Pyramids were designed and used as gnomons, for astronomical purposes; and it is remarkable that their four sides are accurately in the direction of the four cardinal points of the compass, east, west, north, and south.

PYRAMIDAL *Numbers*, are the sums of polygonal numbers, collected after the same manner as the polygonal numbers themselves are found from arithmetical progressions.

These are particularly called First Pyramidals. The sums of First Pyramidals are called Second Pyramidals; and the sums of the 2d are 3d Pyramidals; and so on. Particularly, those arising from triangular numbers, are called Prime Triangular Pyramidals; those arising

from pentagonal numbers, are called Prime Pentagonal Pyramidals; and ſo on.

The numbers	1,	4,	10,	20,	35, &c,
formed by adding the triangulars	1,	3,	6,	10,	15, &c,

are uſually called ſimply by the name of Pyramidals; and the general formula for finding them is $n \times \frac{n-1}{2} \times \frac{n-2}{3}$; ſo the 4th Pyramidal is found by ſubſtituting 4 for n; the 5th by ſubſtituting 5 for n; &c. See FIGURATE *Numbers*, and POLYGONAL *Numbers*.

PYRAMIDOID, is ſometimes uſed for the parabolic ſpindle, or the ſolid formed by the rotation of a ſemiparabola about its baſe or greateſt ordinate. See PARABOLIC *Spindle*.

PYROMETER, or fire-meaſurer, a machine for meaſuring the expanſion of ſolid bodies by heat.

Muſſchenbrock was the firſt inventor of this inſtrument; though it has ſince received ſeveral improvements by other philoſophers. He has given a table of the expanſions of the different metals, with various degrees of heat. Having prepared cylindric rods of iron, ſteel, copper, braſs, tin, and lead, he expoſed them firſt to a Pyrometer with one flame in the middle; then with two flames; then ſucceſſively with three, four, and five flames. The effects were as in the following Table, where the degrees of expanſion are marked in parts equal to the 12500th part of an inch.

Expanſion of	Iron	Steel	Copp.	Braſs	Tin	Lead
By 1 flame	80	85	89	110	153	155
By 2 flames placed cloſe together	117	123	115	220		274
By 2 flames at 2½ inches diſtant	109	94	92	141	219	263
By 3 flames cloſe together	142	168	193	275		
By 4 flames cloſe together	211	270	270	361		
By 5 flames	230	310	310	377		

Tin eaſily melts when heated by two flames placed cloſe together; and lead with three flames cloſe together, when they burn long.

It hence appears that the expanſions of any metal are in a leſs degree than the number of flames: ſo two flames give leſs than a double expanſion, three flames leſs than a triple expanſion, and ſo on, always more and more below the ratio of the number of flames. And the flames placed together cauſe a greater expanſion, than with an interval between them.

For the conſtruction of Muſſchenbroek's Pyrometer, with alterations and improvements upon it by Deſaguliers, ſee Deſag. Exper. Philoſ. vol. 1, pa. 421; ſee alſo Muſſchenbroek's tranſlation of the Experiments of the Academy del Cimento, printed at Leyden in 1731; and for a Pyrometer of a new conſtruction, by which the expanſions of metals in boiling fluids may be examined and compared with Fahrenheit's thermometer, ſee Muſſchenb. Introd. ad Philoſ. Nat. 4to, 1762, vol. 2, pa. 618.

But as it has been obſerved, that Muſſchenbroek's Pyrometer was liable to ſome objections, theſe have been removed in a good meaſure by Ellicott, who has given a deſcription of his improved Pyrometer in the Philoſ. Tranſ. numb. 443; and the ſame may be ſeen in the Abridg. vol. 8, pa. 464. This inſtrument meaſures the expanſions to the 7200th part of an inch; and by means of it, Mr. Ellicott found, upon a medium, that the expanſions of bars of different metals, as nearly of the ſame dimenſions as poſſible, by the ſame degree of heat, were as below:

Gold,	Silver,	Braſs,	Copper,	Iron,	Steel,	Lead.
73	103	95	89	60	56	149

The great difference between the expanſions of iron and braſs, has been applied with good ſucceſs to remove the irregularities in pendulums ariſing from heat. Philoſ. Tranſ. vol. 47, pa. 485.

Mr. Graham uſed to meaſure the minute expanſions of metal bars, by advancing the point of a micrometer ſcrew, till it ſenſibly ſtopped againſt the end of the bar to be meaſured. This ſcrew, being ſmall and very lightly hung, was capable of agreement within the 3000 or 4000th part of an inch. And on this general principle Mr. Smeaton contrived his Pyrometer, in which the meaſures are determined by the contact of a piece of metal with the point of a micrometer-ſcrew. This inſtrument makes the expanſions ſenſible to the 2345th part of an inch. And when it is uſed, both the inſtrument and the bar, to be meaſured, are immerged in a ciſtern of water, heated to any degree, up to boiling, by means of lamps placed under the ciſtern; and the water communicates the ſame degree of heat to the inſtrument and bar, and to a mercurial thermometer immerged in it, for aſcertaining that degree.

With this Pyrometer Mr. Smeaton made ſeveral experiments, which are arranged in a table; and he remarks, that their reſult agrees very well with the proportions of expanſions of ſeveral metals given by Mr. Ellicott. The following Table ſhews how much a foot in length of each metal expands by an increaſe of heat correſponding to 180 degrees of Fahrenheit's thermometer, or to the difference between the temperatures of freezing and boiling water, expreſſed in the 100000th part of an inch.

1.	White glaſs barometer tube	100
2.	Martial regulus of antimony	139
3.	Bliſtered ſteel	138
4.	Hard ſteel	147
5.	Iron	151
6.	Biſmuth	167
7.	Copper, hammered	204
8.	Copper 8 parts, mixed with 1 part tin	218
9.	Caſt braſs	225
10.	Braſs 16 parts, with 1 of tin	229
11.	Braſs wire	232
12.	Speculum metal	232
13.	Spelter ſolder, viz 2 parts braſs and 1 zinc	247

14. Fine

14.	Fine pewter	274
15.	Grain tin	298
16.	Soft ſolder, viz lead 2 and tin 1	301
17.	Zinc 8 parts with tin 1, a little hammered	323
18.	Lead	344
19.	Zinc or ſpelter	353
20.	Zinc hammered half an inch per foot	373

For a farther account of this inſtrument, with its uſe, ſee Philoſ. Tranſ. vol. 48, pa. 598.

Mr. Ferguſon has conſtructed, and deſcribed a Pyrometer (Lect. on Mechanics, Suppl. pa. 7, 4to), which makes the expanſion of metals by heat viſible to the 45000th part of an inch. And another plan of a Pyrometer has lately been invented by M. De Luc, in conſequence of a hint ſuggeſted to him by Mr. Ramſden: for an account of which, with the principle of its conſtruction and uſe, both in the comparative meaſure of the expanſions of bodies by heat, and the meaſure of their abſolute expanſion, as well as the experiments made with it, ſee M. De Luc's elaborate eſſay on Pyrometry &c, in the Philoſ. Tranſ. vol. 68, pa. 419—546.

Other very nice and ingenious contrivances, for the meaſuring of expanſions by heat, have been made by Mr. Ramſden; which he has ſucceſsfully applied in the caſe of the meaſuring rods and chains lately employed, by General Roy and Col. Williams, in meaſuring the baſe on Hounſlow Heath, &c; which determine the expanſions, to great minuteneſs, for each degree of the thermometer. See Philoſ. Tranſ. 1785, &c.

PYROPHORUS, the name uſually given to that ſubſtance by ſome called black phoſphorus; being a chemical preparation poſſeſſing the ſingular property of kindling ſpontaneouſly when expoſed to the air; which was accidentally diſcovered by M. Homberg, who prepared it of alum and human fæces. Though it has ſince been found, by the ſon of M. Lemeri, that the fæces are not neceſſary to it, but that honey, ſugar, flour, and any animal or vegetable matter, may be uſed inſtead of the fæces; and M. De Suvigny has ſhewn that moſt vitriolic ſalts may be ſubſtituted for the alum. See Prieſtley's Obſerv. on Air, vol. 3, Append. p. 386, and vol. 4, Append. p. 479.

PYROTECHNY, the art of fire, or the ſcience which teaches the application and management of fire in ſeveral operations.

Pyrotechny is of two kinds, military and chemical.

Military PYROTECHNY, is the ſcience of artificial fire-works, and fire-arms, teaching the ſtructure and uſe both of thoſe employed in war, as gunpowder, cannon, ſhells, carcaſſes, mines, fuſees, &c; and of thoſe made for amuſement, as rockets, ſtars, ſerpents, &c.

Some call Pyrotechny by the name Artillery; though that word is uſually confined to the inſtruments employed in war. Others chooſe to call it Pyrobology, or rather Pyroballogy, or the art of miſſile fires.

Wolfius has reduced Pyrotechny into a kind of mixt mathematical art. Indeed it will not allow of geometrical demonſtrations; but he brings it to tolerable rules and reaſons; whereas it had formerly been treated by authors at random, and without regard to any reaſons at all. See the ſeveral articles CANNON, GUNPOWDER, ROCKET, SHELL, &c.

Chemical PYROTECHNY, is the art of managing and applying fire in diſtillations, calcinations, and other operations of chemiſtry.

Some reckon a third kind of Pyrotechny, viz, the art of fuſing, refining, and preparing metals.

PYTHAGORAS, one of the greateſt philoſophers of antiquity, was born about the 47th Olympiad, or 590 years before Chriſt. His father's principal reſidence was at Samos, but being a travelling merchant, his ſon Pythagoras was born at Sidon in Syria; but ſoon returning home again, our philoſopher was brought up at Samos, where he was educated in a manner that was anſwerable to the great hopes that were conceived of him. He was called "the youth with a fine head of hair;" and from the great qualities that ſoon appeared in him, he was regarded as a good genius ſent into the world for the benefit of mankind.

Samos however afforded no philoſophers capable of ſatisfying his thirſt for knowledge; and therefore, at 18 years of age, he reſolved to travel in queſt of them elſewhere. The fame of Pherecydes drew him firſt to the iſland of Syros: from hence he went to Miletus, where he converſed with Thales. He then travelled to Phœnicia, and ſtayed ſome time at Sidon, the place of his birth; and from hence he paſſed into Egypt, where Thales and Solon had been before him.

Having ſpent 25 years in Egypt, to acquire all the learning and knowledge he could procure in that country, with the ſame view he travelled through Chaldea, and viſited Babylon. Returning after ſome time, he went to Crete; and from hence to Sparta, to be inſtructed in the laws of Minos and Lycurgus. He then returned to Samos; which, finding under the tyranny of Polycrates, he quitted again, and viſited the ſeveral countries of Greece. Paſſing through Peloponneſus, he ſtopped at Phlius, where Leo then reigned; and in his converſation with that prince, he ſpoke with ſo much eloquence and wiſdom, that Leo was at once raviſhed and ſurpriſed.

From Peloponneſus he went into Italy, and paſſed ſome time at Heraclea, and at Tarentum, but made his chief reſidence at Croton; where, after reforming the manners of the citizens by preaching, and eſtabliſhing the city by wiſe and prudent counſels, he opened a ſchool, to diſplay the treaſures of wiſdom and learning he poſſeſſed. It is not to be wondered, that he was ſoon attended by a crowd of diſciples, who repaired to him from different parts of Greece and Italy.

He gave his ſcholars the rules of the Egyptian prieſts, and made them paſs through the auſterities which he himſelf had endured. He at firſt enjoined them a five years ſilence in the ſchool, during which they were only to hear; after which, leave was given them to ſtart queſtions, and to propoſe doubts, under the caution however, to ſay, "not a little in many words, but much in a few." Having gone through their probation, they were obliged, before they were admitted, to bring all their fortune into the common ſtock, which was managed by perſons choſen on purpoſe, and called œconomiſts, and the whole community had all things in common.

The neceſſity of concealing their myſteries induced the Egyptians to make uſe of three ſorts of ſtyles, or ways of expreſſing their thoughts; the ſimple, the

hieroglyphical, and the ſymbolical. In the ſimple, they ſpoke plainly and intelligibly, as in common converſation; in the hieroglyphical, they concealed their thoughts under certain images and characters; and in the ſymbolical, they explained them by ſhort expreſſions, which, under a ſenſe plain and ſimple, included another wholly figurative. Pythagoras borrowed theſe three different ways from the Egyptians, in all the inſtructions he gave; but chiefly imitated the ſymbolical ſtyle, which he thought very proper to inculcate the greateſt and moſt important truths: for a ſymbol, by its double ſenſe, the proper and the figurative, teaches two things at once; and nothing pleaſes the mind more, than the double image it repreſents to our view.

In this manner Pythagoras delivered many excellent things concerning God and the human ſoul, and a great variety of precepts, relating to the conduct of life, political as well as civil; he made alſo ſome conſiderable diſcoveries and advances in the arts and ſciences. Thus, among the works aſcribed to him, there are not only books of phyſic, and books of morality, like that contained in what are called his *Golden Verſes*, but treatiſes on politics and theology. All theſe works are loſt: but the vaſtneſs of his mind appears from the wonderful things he performed. He delivered, as antiquity relates, ſeveral cities of Italy and Sicily from the yoke of ſlavery; he appeaſed ſeditions in others; and he ſoftened the manners, and brought to temper the moſt ſavage and unruly ſpirits, of ſeveral people and tyrants. Phalaris, the tyrant of Sicily, it is ſaid, was the only one who could withſtand the remonſtrances of Pythagoras; and he it ſeems was ſo enraged at his diſcourſes, that he ordered him to be put to death. But though the lectures of the philoſopher could make no impreſſion on the tyrant, yet they were ſufficient to reanimate the Sicilians, and to put them upon a bold action. In ſhort, Phalaris was killed the ſame day that he had fixed for the death of the philoſopher.

Pythagoras had a great veneration for marriage; and therefore himſelf married at Croton, a daughter of one of the chief men of that city, by whom he had two ſons and a daughter: one of the ſons ſucceeded his father in the ſchool, and became the maſter of Empedocles: the daughter, named Damo, was diſtinguiſhed both by her learning and her virtues, and wrote an excellent commentary upon Homer. It is related, that Pythagoras had given her ſome of his writings, with expreſs commands not to impart them to any but thoſe of his own family; to which Damo was ſo ſcrupulouſly obedient, that even when ſhe was reduced to extreme poverty, ſhe refuſed a great ſum of money for them.

From the country in which Pythagoras thus ſettled and gave his inſtructions, his ſociety of diſciples was called the Italic ſect of philoſophers, and their reputation continued for ſome ages afterwards, when the Academy and the Lycæum united to obſcure and ſwallow up the Italic ſect. Pythagoras's diſciples regarded the words of their maſter as the oracles of a god; his authority alone, though unſupported by reaſon, paſſed with them for reaſon itſelf: they looked on him as the moſt perfect image of God among men. His houſe was called the temple of Ceres, and his court yard the temple of the Muſes; and when he went into towns, it was ſaid he went thither, "not to teach men, but to heal them."

Pythagoras however was perſecuted by bad men in the laſt years of his life; and ſome ſay he was killed in a tumult raiſed by them againſt him; but according to others, he died a natural death, at 90 years of age, about 497 years before Chriſt.

Beſide the high reſpect and veneration the world has always had for Pythagoras, on account of the excellence of his wiſdom, his morality, his theology, and politics, he was renowned as learned in all the ſciences, and a conſiderable inventor of many things in them; as arithmetic, geometry, aſtronomy, muſic, &c. In arithmetic, the common multiplication table is, to this day, ſtill called Pythagoras's table. In geometry, it is ſaid he invented many theorems, particularly theſe three; 1ſt, Only three polygons, or regular plane figures, can fill up the ſpace about a point, viz, the equilateral triangle, the ſquare, and the hexagon: 2d, The ſum of the three angles of every triangle, is equal to two right angles: 3d, In any right-angled triangle, the ſquare on the longeſt ſide, is equal to both the ſquares on the two ſhorter ſides: for the diſcovery of this laſt theorem, ſome authors ſay he offered to the gods a hecatomb, or a ſacrifice of a hundred oxen; Plutarch however ſays it was only one ox, and even that is queſtioned by Cicero, as inconſiſtent with his doctrine, which forbade bloody ſacrifices: the more accurate therefore ſay, he ſacrificed an ox made of flour, or of clay; and Plutarch even doubts whether ſuch ſacrifice, whatever it was, was made for the ſaid theorem, or for the area of the parabola, which it was ſaid Pythagoras alſo found out.

In aſtronomy his inventions were many and great. It is reported he diſcovered, or maintained the true ſyſtem of the world, which places the ſun in the centre, and makes all the planets revolve about him; from him it is to this day called the old or Pythagorean ſyſtem; and is the ſame as that lately revived by Copernicus. He firſt diſcovered, that Lucifer and Heſperus were but one and the ſame, being the planet Venus, though formerly thought to be two different ſtars. The invention of the obliquity of the zodiac is likewiſe aſcribed to him. He firſt gave to the world the name Κοσμος, *Koſmos*, from the order and beauty of all things comprehended in it; aſſerting that it was made according to muſical proportion: for as he held that the ſun, by him and his followers termed the fiery globe of unity, was ſeated in the midſt of the univerſe, and the earth and planets moving around him, ſo he held that the ſeven planets had an harmonious motion, and their diſtances from the ſun correſponded to the muſical intervals or diviſions of the monochord.

Pythagoras and his followers held the tranſmigration of ſouls, making them ſucceſſively occupy one body after another: on which account they abſtained from fleſh, and lived chiefly on vegetables.

PYTHAGORAS's *Table*, the ſame as the multiplication-table; which ſee.

PYTHAGOREAN, or PYTHAGORIC *Syſtem*, among the Ancients, was the ſame as the Copernican ſyſtem among the Moderns. In this ſyſtem, the ſun is ſuppoſed at reſt in the centre, with the earth and all the planets revolving about him, each in their orbits. See SYSTEM.

It was ſo called, as having been maintained and cultivated by Pythagoras, and his followers; not that it was invented by him, for it was much older.

PYTHAGOREAN *Theorem*, is that in the 47th propoſition of the 1ſt book of Euclid's Elements; viz, that in a right-angled triangle, the ſquare of the longeſt ſide, is equal to the ſum of both the ſquares of the two ſhorter ſides. It has been ſaid that Pythagoras offered a hecatomb, or ſacrifice of 100 oxen, to the gods, for inſpiring him with the diſcovery of ſo remarkable a property.

PYTHAGOREANS, a ſect of ancient philoſophers, who followed the doctrines of Pythagoras. They were otherwiſe called the Italic ſect, from the circumſtance of his having ſettled in Italy. Out of his ſchool proceeded the greateſt philoſophers and legiſlators, Zaleucus, Charondas, Archytas, &c. See the article PYTHAGORAS.

PYXIS *Nautica*, the ſeaman's compaſs.

Q.

QUA

QUADRAGESIMA, a denomination given to the time of Lent, from its conſiſting of about 40 days; commencing on Aſh Wedneſday.

QUADRAGESIMA *Sunday*, is the firſt Sunday in Lent, or the 1ſt Sunday after Aſh Wedneſday.

QUADRANGLE, or QUADRANGULAR *figure*, in Geometry, is a plane figure having four angles; and conſequently four ſides alſo.

To the claſs of Quadrangles belong the ſquare, parallelogram, trapezium, rhombus, and rhomboides.—A ſquare is a regular Quadrangle; a trapezium an irregular one.

QUADRANT, in Geometry, is either the quarter or 4th part of a circle, or the 4th part of its circumference; the arch of which therefore contains 90 degrees.

QUADRANT alſo denotes a mathematical inſtrument, of great uſe in aſtronomy and navigation, for taking the altitudes of the ſun and ſtars, as alſo taking angles in ſurveying, heights-and-diſtances, &c.

This inſtrument is variouſly contrived, and furniſhed with different apparatus, according to the various uſes it is intended for; but they have all this in common, that they conſiſt of the quarter of a circle, whoſe limb or arch is divided into 90° &c. Some have a plummet ſuſpended from the centre, and are furniſhed either with plain ſights, or a teleſcope, to look through.

The principal and moſt uſeful Quadrants, are the common Surveying Quadrant, the Aſtronomical Quadrant, Adams's Quadrant, Cole's Quadrant, Collins's or Sutton's Quadrant, Davis's Quadrant, Gunter's Quadrant, Hadley's Quadrant, the Horodictical Quadrant, and the Sinical Quadrant, &c. Of theſe in their order.

1. *The Common, or Surveying* QUADRANT.—This inſtrument ABC, fig. 1, pl. 24, is made of braſs, or wood, &c; the limb or arch of which BC is divided into 90°, and each of theſe farther divided into as many equal parts as the ſpace will allow, either diagonally or otherwiſe. On one of the radii AC, are fitted two moveable ſights; and to the centre is ſometimes alſo annexed a label, or moveable index AD, bearing two other ſights; but inſtead of theſe laſt ſights, there is ſometimes fitted a teleſcope. Alſo from the centre hangs a thread with a plummet; and on the under ſide or face of the inſtrument is fitted a ball and ſocket, by means of which it may be put into any poſition. The general uſe of it is for taking angles in a vertical plane, comprehended under right lines going from the centre of the inſtrument, one of which is horizontal, and the other is directed to ſome viſible point. But beſides the parts above deſcribed, there is often added on the face, near the centre, a kind of compartment EF, called a Quadrat, or Geometrical Square, which is a kind of ſeparate inſtrument, and is particularly uſeful in Altimetry and Longimetry, or Heights-and-Diſtances.

This Quadrant may be uſed in different ſituations; in each of them, the plane of the inſtrument muſt be ſet parallel to that of the eye and the objects whoſe angular diſtance is to be taken. Thus, for obſerving heights or depths, its plane muſt be diſpoſed vertically, or perpendicular to the horizon; but to take horizontal angles or diſtances, its plane muſt be diſpoſed parallel to the horizon.

Again, heights and diſtances may be taken two ways, viz, by means of the fixed ſights and plummet, or by the label; as alſo, either by the degrees on the limb, or by the Quadrat. Thus, fig. 2 pl. 24 ſhews the manner of taking an angle of elevation with this Quadrant; the eye is applied at C, and the inſtrument turned vertically about the centre A, till the object R be ſeen through the ſights on the radius AC; then the angle of elevation RAH, made with the horizontal line KAH, is equal to the angle BAD, made by the plumb line and the other radius of the Quadrant, and the quantity of it is ſhewn by the degrees in the arch BD cut off by the plumb line AD.

See the uſe of the inſtrument in my Menſuration, under the ſection of Heights-and-Diſtances.

2. *The Aſtronomical* QUADRANT, is a large one, uſu-

ally

ally made of braſs or iron bars; having its limb EF (fig. 3 pl. 24) nicely divided, either diagonally or otherwiſe, into degrees, minutes, and ſeconds, if room will permit, and furniſhed either with two pair of plain ſights or two teleſcopes, one on the ſide of the Quadrant at AB, and the other CD moveable about the centre by means of the ſcrew G. The dented wheels I and H ſerve to direct the inſtrument to any object or phenomenon.

The application of this uſeful inſtrument, in taking obſervations of the ſun, planets, and fixed ſtars, is obvious; for being turned horizontally upon its axis, by means of the teleſcope AB, till the object is ſeen through the moveable teleſcope, then the degrees &c cut by the index, give the altitude &c required.

3. *Cole's* QUADRANT, is a very uſeful inſtrument, invented by Mr. Benjamin Cole. It conſiſts of ſix parts, viz, the ſtaff AB (fig. 11 pl. 24); the quadrantal arch DE; three vanes A, B, C; and the vernier FG. The ſtaff is a bar of wood about 2 feet long, an inch and a quarter broad, and of a ſufficient thickneſs to prevent it from bending or warping. The quadrantal arch is alſo of wood; and is divided into degrees and 3d parts of degrees, to a radius of about 9 inches; and to its extremities are fitted two radii, which meet in the centre of the Quadrant by a pin, about which it eaſily moves. The ſight-vane A is a thin piece of braſs, near two inches in height, and one broad, ſet perpendicularly on the end of the ſtaff A, by means of two ſcrews paſſing through its foot. In the middle of this vane is drilled a ſmall hole, through which the coincidence or meeting of the horizon and ſolar ſpot is to be viewed. The horizon-vane B is about an inch broad, and 2 inches and a half high, having a ſlit cut through it of near an inch long, and a quarter of an inch broad; this vane is fixed in the centre-pin of the inſtrument, in a perpendicular poſition, by means of two ſcrews paſſing through its foot, by which its poſition with reſpect to the ſight-vane is always the ſame, their angle of inclination being equal to 45 degrees. The ſhade-vane C is compoſed of two braſs plates. The one, which ſerves as an arm, is about $4\frac{1}{2}$ inches long, and $\frac{3}{4}$ of an inch broad, being pinned at one end to the upper limb of the Quadrant by a ſcrew, about which it has a ſmall motion; the other end lies in the arch, and the lower edge of the arm is directed to the middle of the centre-pin: the other plate, which is properly the vane, is about 2 inches long, being fixed perpendicularly to the other plate, at about half an inch diſtance from that end next the arch; this vane may be uſed either by its ſhade, or by the ſolar ſpot caſt by a convex lens placed in it. And becauſe the wood-work is often ſubject to warp or twiſt, therefore this vane may be rectified by means of a ſcrew, ſo that the warping of the inſtrument may occaſion no error in the obſervation, which is performed in the following manner: Set the line G on the vernier againſt a degree on the upper limb of the Quadrant, and turn the ſcrew on the backſide of the limb forward or backward, till the hole in the ſight-vane, the centre of the glaſs, and the ſunk ſpot in the horizon-vane, lie in a right line.

To find the Sun's Altitude by this inſtrument. Turn your back to the ſun, holding the ſtaff of the inſtrument with the right hand, ſo that it be in a vertical plane paſſing through the ſun; apply one eye to the ſight-vane, looking through that and the horizon-vane till the horizon be ſeen; with the left hand ſlide the quadrantal arch upwards, till the ſolar ſpot or ſhade, caſt by the ſhade-vane, fall directly upon the ſpot or ſlit in the horizon-vane; then will that part of the quadrantal arch, which is raiſed above G or S (according as the obſervation reſpects either the ſolar ſpot or ſhade) ſhew the altitude of the ſun at that time. But for the meridian altitude, the obſervation muſt be continued, and as the ſun approaches the meridian, the ſea will appear through the horizon-vane, which completes the obſervation; and the degrees and minutes, counted as before, will give the ſun's meridian altitude: or the degrees counted from the lower limb upwards will give the zenith diſtance.

4. *Adams's* QUADRANT, differs only from Cole's Quadrant, juſt deſcribed, in having an horizontal vane, with the upper part of the limb lengthened; ſo that the glaſs, which caſts the ſolar ſpot on the horizon-vane, is at the ſame diſtance from the horizon-vane as the ſight-vane at the end of the index.

5. *Collins's* or *Sutton's* QUADRANT, (fig. 8 pl. 24) is a ſtereographic projection of one quarter of the ſphere between the tropics, upon the plane of the ecliptic, the eye being in its north pole; and fitted to the latitude of London. The lines running from right to left, are parallels of altitude; and thoſe croſſing them are azimuths. The ſmaller of the two circles, bounding the projection, is one quarter of the tropic of Capricorn; and the greater is a quarter of the tropic of Cancer. The two ecliptics are drawn from a point on the left edge of the Quadrant, with the characters of the ſigns upon them; and the two horizons are drawn from the ſame point. The limb is divided both into degrees and time; and by having the ſun's altitude, the hour of the day may here be found to a minute. The quadrantal arches next the centre contain the calendar of months; and under them, in another arch, is the ſun's declination. On the projection are placed ſeveral of the moſt remarkable fixed ſtars between the tropics; and the next below the projection is the Quadrant and line of ſhadows.

To find the Time of the Sun's Riſing or Setting, his Amplitude, his Azimuth, Hour of the Day, &c. by this Quadrant. Lay the thread on the day and the month, and bring the bead to the proper ecliptic, either of ſummer or winter, according to the ſeaſon, which is called *rectifying*; then by moving the thread bring the bead to the horizon, in which caſe the thread will cut the limb in the point of the time of the ſun's riſing or ſetting before or after 6: and at the ſame time the bead will cut the horizon in the degrees of the ſun's amplitude.—Again, obſerving the ſun's altitude with the Quadrant, and ſuppoſing it found to be 45° on the 5th of May, lay the thread over the 5th of May; then bring the bead to the ſummer ecliptic, and carry it to the parallel of altitude 45°; in which caſe the thread will cut the limb at 55° 15′, and the hour will be ſeen among the hour-lines to be either 41m. paſt 9 in the morning, or 19m. paſt 2 in the afternoon.——Laſtly, the bead ſhews among the azimuths the ſun's diſtance from the ſouth 50° 41′.

But note, that if the ſun's altitude be leſs than what it is at 6 o'clock, the operation muſt be performed among thoſe parallels above the upper horizon; the bead being rectified to the winter ecliptic.

6. *Davis's* QUADRANT, the ſame as the BACK-STAFF; which ſee.

7. *Gunner's* QUADRANT, (fig. 6 pl. 24), ſometimes called the *Gunner's Square*, is uſed for elevating and pointing cannon, mortars, &c. and conſiſts of two branches either of wood or braſs, between which is a quadrantal arch divided into 90°, and furniſhed with a thread and plummet.

The uſe of this inſtrument is very eaſy; for if the longer branch, or bar, be placed in the mouth of the piece, and it be elevated till the plummet cut the degree neceſſary to hit a propoſed object, the thing is done.

Sometimes on the ſides of the longer bar, are noted the diviſion of diameters and weights of iron balls, as alſo the bores of pieces.

8. *Gunter's* QUADRANT, ſo called from its inventor Edmund Gunter, (fig. 4 pl. 24) beſide the apparatus of other Quadrants, has a ſtereographic projection of the ſphere on the plane of the equinoctial; and alſo a calendar of the months, next to the diviſions of the limb; by which, beſide the common purpoſes of other Quadrants, ſeveral uſeful queſtions in aſtronomy, &c, are eaſily reſolved.

Uſe of Gunter's Quadrant. — 1. To find the ſun's meridian altitude for any given day, or converſely the day of the year anſwering to any given meridian altitude. Lay the thread to the day of the month in the ſcale next the limb; then the degree it cuts in the limb is the ſun's meridian altitude. And, contrariwiſe, the thread being ſet to the meridian altitude, it ſhews the day of the month.

2. To find the hour of the day. Having put the bead, which ſlides on the thread, to the ſun's place in the ecliptic, obſerve the ſun's altitude by the Quadrant; then if the bead be laid over the ſame in the limb, the bead will fall upon the hour required. On the contrary, laying the bead on a given hour, having firſt rectified or ſet it to the ſun's place, the degree cut by the thread on the limb gives the altitude.

Note, the bead may be rectified otherwiſe, by bringing the thread to the day of the month, and the bead to the hour-line of 12.

3. To find the ſun's declination from his place given; and the contrary. Bring the bead to the ſun's place in the ecliptic, and move the thread to the line of declination E T, ſo ſhall the bead cut the degree of declination required. On the contrary, the bead being adjuſted to a given declination, and the thread moved to the ecliptic, the bead will cut the ſun's place.

4. The ſun's place being given, to find the right aſcenſion; or contrariwiſe. Lay the thread on the ſun's place in the ecliptic, and the degree it cuts on the limb is the right aſcenſion ſought. And the converſe.

5. The ſun's altitude being given, to find his azimuth; and contrariwiſe. Rectify the bead for the time, as in the ſecond article, and obſerve the ſun's altitude; bring the thread to the complement of that altitude; then the bead will give the azimuth ſought, among the azimuth-lines.

9. *Hadley's* QUADRANT, (fig. 7 pl. 24) ſo called from its inventor John Hadley, Eſq, is now univerſally uſed as the beſt of any for nautical and other obſervations.

It ſeems the firſt idea of this excellent inſtrument was ſuggeſted by Dr. Hooke; for Dr. Sprat, in his Hiſtory of the Royal Society, pa. 246, mentions the invention of a new inſtrument for taking angles by reflection, by which means the eye at once ſees the two objects both as touching the ſame point, though diſtant almoſt to a ſemicircle; which is of great uſe for making exact obſervations at ſea. This inſtrument is deſcribed and illuſtrated by a figure in Hooke's Poſthumous works, pa. 503. But as it admitted of only one reflection, it would not anſwer the purpoſe. The matter however was at laſt effected by Sir Iſaac Newton, who communicated to Dr. Halley a paper of his own writing, containing the deſcription of an inſtrument with two reflections, which ſoon after the doctor's death was found among his papers by Mr. Jones, by whom it was communicated to the Royal Society, and it was publiſhed in the Philoſ. Tranſ. for the year 1742. See alſo the Abridg. vol. 8, pa. 129. How it happened that Dr. Halley never mentioned this in his lifetime, is hard to ſay; but it is very extraordinary; more eſpecially as Mr. Hadley had deſcribed, in the Tranſac. for 1731, his inſtrument, which is conſtructed on the ſame principles. See alſo Abr. vol. 6, pa. 139. Mr. Hadley, who was well acquainted with Sir Iſaac Newton, might have heard him ſay, that Dr. Hooke's propoſal could be effected by means of a double reflection; and perhaps in conſequence of this hint, he might apply himſelf, without any previous knowledge of what Newton had actually done, to the conſtruction of his inſtrument. Mr. Godfrey too, of Pennſylvania, had recourſe to a ſimilar expedient; for which reaſon ſome gentlemen of that colony have aſcribed the invention of this excellent inſtrument to him. The truth may probably be, that each of theſe gentlemen diſcovered the method independent of one another. See Abr. Philoſ. Tranſ. vol. 8, pa. 366; alſo Tranſ. of the American Society, vol. 1, pa. 21 Appendix.

This inſtrument conſiſts of the following particulars: 1. An octant, or the 8th part of a circle, ABC. 2. An index D. 3. The ſpeculum E. 4. Two horizontal glaſſes, F, G. 5. Two ſcreens, K and K. 6. Two ſight-vanes, H and I.

The octant conſiſts of two radii, AB, AC, ſtrengthened by the braces L, M, and the arch BC; which, though containing only 45°, is nevertheleſs divided into 90 primary diviſions, each of which ſtands for degrees, and are numbered 0, 10, 20, 30, &c, to 90; beginning at each end of the arch for the convenience of numbering both ways, either for altitudes or zenith diſtances: alſo each degree is ſubdivided into minutes, by means of a vernier. But the number of theſe diviſions varies with the ſize of the inſtrument.

The index D, is a flat bar, moveable about the centre of the inſtrument; and that part of it which ſlides over the graduated arch, BC, is open in the middle, with Vernier's ſcale on the lower part of it;

and

and underneath is a ſcrew, ſerving to faſten the index againſt any diviſion.

The ſpeculum E is a piece of flat glaſs, quickſilvered on one ſide, ſet in a braſs box, and placed perpendicular to the plane of the inſtrument, the middle part of the former coinciding with the centre of the latter: and becauſe the ſpeculum is fixed to the index, the poſition of it will be altered by the moving of the index along the arch. The rays of an obſerved object are received on the ſpeculum, and from thence reflected on one of the horizon glaſſes, F or G; which are two ſmall pieces of looking glaſs placed on one of the limbs, their faces being turned obliquely to the ſpeculum, from which they receive the reflected rays of objects. This glaſs F has only its lower part ſilvered, and ſet in braſs-work; the upper part being left tranſparent to view the horizon. The glaſs G has in its middle a tranſparent ſlit, through which the horizon is to be ſeen. And becauſe the warping of the materials, and other accidents, may diſtend them from their true ſituation, there are three ſcrews paſſing through their feet, by which they may be eaſily replaced.

The ſcreens are two pieces of coloured glaſs, ſet in two ſquare braſs frames K and K, which ſerve as ſcreens to take off the glare of the ſun's rays, which would otherwiſe be too ſtrong for the eye; the one is tinged much deeper than the other; and as they both move on the ſame centre, they may be both or either of them uſed: in the ſituation they appear in the figure, they ſerve for the horizon-glaſs F; but when they are wanted for the horizon-glaſs G, they muſt be taken from their preſent ſituation, and placed on the Quadrant above G.

The ſight-vanes are two pins, H and I, ſtanding perpendicularly to the plane of the inſtrument: that at H has one hole in it, oppoſite to the tranſparent ſlit in the horizon-glaſs G; the other, at I, has two holes in it, the one oppoſite to the middle of the tranſparent part of the horizon-glaſs F, and the other rather lower than the quick-ſilvered part: this vane has a piece of braſs on the back of it, which moves round a centre, and ſerves to cover either of the holes.

Of the Obſervations.—There are two ſorts of obſervations to be made with this inſtrument: the one is when the back of the obſerver is turned towards the object, and therefore called the *back obſervation*; the other when the face of the obſerver is turned towards the object, which is called the *fore-obſervation*.

To Rectify the Inſtrument for the Fore-obſervation: Slacken the ſcrew in the middle of the handle behind the glaſs F; bring the index cloſe to the button *b*; hold the inſtrument in a vertical poſition, with the arch downwards; look through the right-hand hole in the vane I, and through the tranſparent part of the glaſs F, for the horizon; and if it lie in the ſame right line with the image of the horizon ſeen on the ſilvered part, the glaſs F is rightly adjuſted; but if the two horizontal lines diſagree, turn the ſcrew which is at the end of the handle backward or forward, till thoſe lines coincide; then faſten the middle ſcrew of the handle, and the glaſs is rightly adjuſted.

To take the Sun's Altitude by the Fore-obſervation. Having fixed the ſcreens above the horizon-glaſs F, and ſuited them proportionally to the ſtrength of the ſun's rays, turn your face towards the ſun, holding the inſtrument with your right hand, by the braces L and M, in a vertical poſition, with the arch downward; put your eye cloſe to the right-hand hole in the vane I, and view the horizon through the tranſparent part of the horizon-glaſs F, at the ſame time moving the index D with the left hand, till the reflex ſolar ſpot coincides with the line of the horizon; then the degrees counted from C, or that end next your body, will give the ſun's altitude at that time, obſerving to add or ſubtract 16 minutes according as the upper or lower edge of the ſun's reflex image is made uſe of.

But to get the ſun's meridian altitude, which is the thing wanted for finding the latitude; the obſervations muſt be continued; and as the ſun approaches the meridian the index D muſt be continually moved towards B, to maintain the coincidence between the reflex ſolar ſpot and the horizon; and conſequently as long as this motion can maintain the ſame coincidence, the obſervation muſt be continued, till the ſun has reached the meridian, and begins to deſcend, when the coincidence will require a retrograde motion of the index, or towards C; and then the obſervation is finiſhed, and the degrees counted as before will give the ſun's meridian altitude, or thoſe from B will give the zenith diſtance; obſerving to add the ſemi-diameter, or 16′, when his lower edge is brought to the horizon; or to ſubtract 16′, when the horizon and upper edge coincide.

To take the Altitude of a Star by the Fore-obſervation. Through the vane H, and the tranſparent ſlit in the glaſs G, look directly to the ſtar; and at the ſame time move the index, till the image of the horizon behind you, being reflected by the great ſpeculum, be ſeen in the ſilvered part of G, and meet the ſtar; then will the index ſhew the degrees of the ſtar's altitude.

To Rectify the Inſtrument for the Back-obſervation. Slacken the ſcrew in the middle of the handle, behind the glaſs G; turn the button *h* on one ſide, and bring the index as many degrees before o as is equal to double the dip of the horizon at your height above the water; hold the inſtrument vertical, with the arch downward; look through the hole of the vane H; and if the horizon, ſeen through the tranſparent ſlit in the glaſs G, coincide with the image of the horizon ſeen in the ſilvered part of the ſame glaſs, then the glaſs G is in its proper poſition; but if not, ſet it by the handle, and faſten the ſcrew as before.

To take the Sun's Altitude by the Back-obſervation. Put the ſtem of the ſcreens K and K into the hole *r*, and in proportion to the ſtrength or faintneſs of the ſun's rays, let either one or both or neither of the frames of thoſe glaſſes be turned cloſe to the face of the limb; hold the inſtrument in a vertical poſition, with the arch downward, by the braces L and M, with the left hand; turn your back to the ſun, and put one eye cloſe to the hole in the vane H, obſerving the horizon through the tranſparent ſlit in the horizon glaſs G; with the right hand move the index D, till the reflected image of the ſun be ſeen in the ſilvered part of the glaſs G, and in a right line with the horizon; ſwing your body to and fro, and if the obſervation be well made, the ſun's image will be obſerved to bruſh the horizon, and the degrees reckoned from C, or that part of the arch fartheſt from your body

body, will give the ſun's altitude at the time of obſervation; obſerving to add 16′ or the ſun's ſemidiameter if the ſun's upper edge be uſed, and ſubtract the ſame for the lower edge.

The directions juſt given, for taking altitudes at ſea, would be ſufficient, but for two corrections that are neceſſary to be made before the altitude can be accurately determined, viz, one on account of the obſerver's eye being raiſed above the level of the ſea, and the other on account of the refraction of the atmoſphere, eſpecially in ſmall altitudes.

The following tables therefore ſhew the corrections to be made on both theſe accounts.

TABLE I.

Dip of the Horizon of the Sea.

Height of the Eye.	Dip of the Horizon.
Feet.	′ ″
1	0 57
2	1 21
3	1 39
5	2 8
10	3 1
15	3 42
20	4 16
25	4 46
30	5 14
35	5 39
40	6 2
45	6 24
50	6 44

TABLE II.

Refractions of the Stars &c in Altitude.

Appar. Altitude in Deg.	Refraction.	Appar. Altitude in Deg.	Refraction.
°	′ ″	°	′ ″
0	33 0	11	4 47
¼	30 35	12	4 23
½	28 22	15	3 30
1	24 29	20	2 35
2	18 35	25	2 2
3	14 36	30	1 38
4	11 51	35	1 21
5	9 54	40	1 8
6	8 29	45	0 57
7	7 20	50	0 48
8	6 29	60	0 33
9	5 48	70	0 21
10	5 15	80	0 10

General Rules for theſe Corrections.

1. In the fore-obſervations, add the ſum of both corrections to the obſerved zenith diſtance, for the true zenith diſtance: or ſubtract the ſaid ſum from the obſerved altitude, for the true one. 2. In the back-obſervation, add the dip and ſubtract the refraction, for altitudes; and for zenith diſtances, do the contrary, viz, ſubtract the dip, and add the refraction.

Example. By a back obſervation, the altitude of the ſun's lower edge was found by Hadley's Quadrant to be 25° 12′; the eye being 30 feet above the horizon. By the tables, the dip on 30 feet is 5′ 14″, and the refraction on 25° 12′ is 2′ 1″. Hence

Appar. alt. lower limb	25°	12′	0″
Sun's ſemidiameter, ſub.	0	16	0
Appar. alt. of centre	24	56	0
Dip. of horizon, add	0	5	14
	25	1	14
Refraction, ſubtract	0	2	1
True alt. of centre	24	59	13

In the caſe of the moon, beſides the two corrections above, another is to be made for her parallaxes. But for all theſe particulars, ſee the Requiſite Tables for the Nautical Almanac, alſo Robertſon's Navigation, vol. 2, pa. 340 &c, edit. 1780.

10. *Horodictical* QUADRANT, a pretty commodious inſtrument, and is ſo called from its uſe in telling the hour of the day. Its conſtruction is as follows. From the centre of the Quadrant C, (fig. 5 pl. 24), whoſe limb AB is divided into 90°, deſcribe ſeven concentric circles at any intervals; and to theſe add the ſigns of the zodiac, in the order repreſented in the figure. Then, applying a ruler to the centre C and the limb A B, mark upon the ſeveral parallels the degrees corresponding to the altitude of the ſun, when in them, for the given hours; connect the points belonging to the ſame hour with a curve line, to which add the number of the hour. To the radius CA fit a couple of ſights, and to the centre of the Quadrant C tie a thread with a plummet, and upon the thread a bead to ſlide.

Now if the bead be brought to the parallel in which the ſun is, and the Quadrant be directed to the ſun, till a viſual ray paſs through the ſights, the bead will ſhew the hour. For the plummet, in this ſituation, cuts all the parallels in the degrees corresponding to the ſun's altitude. And ſince the bead is in the parallel which the ſun deſcribes, and becauſe hour-lines paſs through the degrees of altitude to which the ſun is elevated every hour, therefore the bead muſt ſhew the preſent hour.

11. *Sinical* QUADRANT, is one of ſome uſe in Navigation. It conſiſts of ſeveral concentric quadrantal arches, divided into 8 equal parts by means of radii, with parallel right lines croſſing each other at right angles. Now any one of the arches, as BC, (fig. 10 pl. 24) may repreſent a Quadrant of any great circle of the ſphere, but is chiefly uſed for the horizon or meridian. If then BC be taken for a Quadrant of the horizon, either of the ſides, as AB, may repreſent the meridian; and the other ſide, AC, will repreſent a parallel, or line of eaſt-and-weſt; all the other lines, parallel to AB, will be alſo meridians; and all thoſe parallel to AC, eaſt-and-weſt lines, or parallels. Again, the eight ſpaces into which the arches are divided by the radii, repreſent the eight points of the compaſs in a quarter of the horizon; each containing 11° 15′. The arch BC is likewiſe divided into 90°, and each degree ſubdivided into 12′, diagonalwiſe. To the centre is fixed a thread, which, being laid over any degree of the Quadrant, ſerves to divide the horizon.

If the ſinical Quadrant be taken for a fourth part of the meridian, one ſide of it, AB, may be taken for the common radius of the meridian and equator; and then the other, AC, will be half the axis of the world. The degrees of the circumference, BC, will repreſent degrees of latitude; and the parallels to the ſide AB, aſſumed from every point of latitude to the axis AC, will be radii of the parallels of latitude, as likewiſe the coſine of thoſe latitudes.

Hence, ſuppoſe it be required to find the degrees of longitude contained in 83 of the leſſer leagues in the parallel of 48°: lay the thread over 48° of latitude on the circumference, and count thence the 83 leagues on AB, beginning at A; this will terminate in H, allowing

ing every ſmall interval four leagues. Then tracing out the parallel HE, from the point H to the thread; the part AE of the thread ſhews that 125 greater or equinoctial leagues make 6° 15′; and therefore that the 83 leſſer leagues AH, which make the difference of longitude of the courſe, and are equal to the radius of the parallel HE, make 6° 15′ of the ſaid parallel.

When the ſhip ſails upon an oblique courſe, ſuch courſe, beſide the north and ſouth greater leagues, gives leſſer leagues eaſterly and weſterly, to be reduced to degrees of longitude of the equator. But theſe leagues being made neither on the parallel of departure, nor on that of arrival, but in all the intermediate ones, there muſt be found a mean proportional parallel between them. To find this, there is on the inſtrument a ſcale of croſs latitudes. Suppoſe then it were required to find a mean parallel between the parallels of 40° and 60°; take with the compaſſes the middle between the 40th and 60th degree on the ſcale: this middle point will terminate againſt the 51ſt degree, which is the mean parallel ſought.

The chief uſe of the ſinical Quadrant, is to form upon it triangles ſimilar to thoſe made by a ſhip's way with the meridians and parallels; the ſides of which triangles are meaſured by the equal intervals between the concentric Quadrants and the lines N and S, E and W: and every 5th line and arch is made deeper than the reſt. Now ſuppoſe a ſhip has ſailed 150 leagues north-eaſt-by-north, or making an angle of 33° 45′ with the north part of the meridian: here are given the courſe and diſtance ſailed, by which a triangle may be formed on the inſtrument ſimilar to that made by the ſhip's courſe; and hence the unknown parts of the triangle may be found. Thus, ſuppoſing the centre A to repreſent the place of departure; count, by means of the concentric circles along the point the ſhip ſailed on, viz, AD, 150 leagues: then in the triangle AED, ſimilar to that of the ſhip's courſe, find AE = difference of latitude, and DE = difference of longitude, which muſt be reduced according to the parallel of latitude come to.

Sutton's QUADRANT. See *Collins's* QUADRANT.

12. QUADRANT *of Altitude*, (fig. 9 pl. 24) is an appendix to the artificial globe, conſiſting of a thin ſlip of braſs, the length of a quarter part of one of the great circles of the globe, and graduated. At the end, where the diviſion terminates, is a nut riveted on, and furniſhed with a ſcrew, by means of which the inſtrument is fitted on the meridian, and moveable round upon the rivet to all points of the horizon, as repreſented in the figure referred to.—Its uſe is to ſerve as a ſcale in meaſuring of altitudes, amplitudes, azimuths, &c.

QUADRANTAL *Triangle*, is a ſpherical triangle, which has one ſide equal to a quadrant or quarter part of a circle.

QUADRAT, called alſo *Geometrical Square*, and *Line of Shadows*: it is often an additional member on the face of Gunter's and Sutton's quadrants; and is chiefly uſeful in taking heights or depths. See my Menſuration, the chap. on Altimetry and Longimetry, or Heights and Diſtances.

QUADRAT, in Aſtrology, is the ſame as quartile, being an aſpect of the heavenly bodies when they are diſtant from each other a quadrant, or 90°, or 3 ſigns, and is thus marked □.

QUADRATIC *Equations*, in Algebra, are thoſe in which the unknown quantity is of two dimenſions, or raiſed to the 2d power. See EQUATION.

Quadratic equations are either ſimple, or affected, that is compound.

A Simple QUADRATIC *equation*, is that which contains the 2d power only of the unknown quantity, without any other power of it: as $x^2 = 25$, or $y^2 = ab$. And in this caſe, the value of the unknown quantity is found by barely extracting the ſquare root on both ſides of the equation: ſo in the equations above, it will be $x = \pm 5$, and $y = \pm \sqrt{ab}$; where the ſign of the root of the known quantity is to be taken either plus or minus, for either of theſe may be conſidered as the ſign of the value of the root x, ſince either of theſe, when ſquared, make the ſame ſquare, $\overline{+5}|^2 = 25$, and $\overline{-5}|^2 = 25$ alſo; and hence the root of every quadratic or ſquare, has two values.

Compound or *Affected* QUADRATICS, are thoſe which contain both the 1ſt and 2d powers of the unknown quantity; as $x^2 + ax = b$, or $x^{2n} - ax^n = \pm b$, where n may be of any value, and then x^n is to be conſidered as the root or unknown quantity.

Affected quadratics are uſually diſtinguiſhed into three forms, according to the ſigns of the terms of the equation:

Thus, 1ſt form, $x^2 + ax = b$,
2d form, $x^2 - ax = b$,
3d form, $x^2 - ax = -b$.

But the method of extracting the root, or finding the value of the unknown quantity x, is the ſame in all of them. And that method is uſually performed by what is called completing the ſquare, which is done by taking half the coefficient of the 2d term or ſingle power of the unknown quantity, then ſquaring it, and adding that ſquare to both ſides of the equation, which makes the unknown ſide a complete ſquare. Thus, in the equation $x^2 + ax = b$, the coefficient of the 2d term being a, its half is $\frac{1}{2}a$, the ſquare of which is $\frac{1}{4}a^2$, and this added to both ſides of the equation, it becomes $x^2 + ax + \frac{1}{4}a^2 = \frac{1}{4}a^2 + b$, the former ſide of which is now a complete ſquare. The ſquare being thus completed, its root is next to be extracted; in order to which, it is to be obſerved that the root on the unknown ſide conſiſts of two terms, the one of which is always x the ſquare root of the firſt term of the equation, and the other part is $\frac{1}{2}a$ or half the coefficient of the 2d term: thus then the root of $x^2 + ax + \frac{1}{4}a^2$ the firſt ſide of the completed equation being $x + \frac{1}{2}a$, and the root of the other ſide $\frac{1}{4}a^2 + b$ being $\pm \sqrt{a^2 + b}$, it follows that $x + \frac{1}{2}a = \pm \sqrt{\frac{1}{4}a^2 + b}$, and hence, by tranſpoſing $\frac{1}{2}a$, it is $x = -\frac{1}{2}a \pm \sqrt{\frac{1}{4}a^2 + b}$, the two values of x, or roots of the given equation $x^2 + a = b$. And thus is found the root, or value of x, in the three forms of equations above mentioned: thus,

1ſt form $x = -\frac{1}{2}a \pm \sqrt{\frac{1}{4}a^2 + b}$,
2d form $x = +\frac{1}{2}a \pm \sqrt{\frac{1}{4}a^2 + b}$,
3d form $x = +\frac{1}{2}a \pm \sqrt{\frac{1}{4}a^2 - b}$.

Where

Where it is obſervable that, becauſe of the double ſign ±, every form has two roots: in the 1ſt and 2d forms thoſe roots are the one poſitive and the other negative, the poſitive root being the leſs of the two in the 1ſt form, but the greater in the 2d form; and in the 3d form the roots are both poſitive. Again, the two roots of the 1ſt and 2d forms, are always both of them real; but in the 3d form, the two roots are either both real or both imaginary, viz, both real when $\frac{1}{4}a^2$ is greater than b, or both imaginary when $\frac{1}{4}a^2$ is leſs than b, becauſe in this caſe $\frac{1}{4}a^2 - b$ will be a negative quantity, the root of which is impoſſible, or an imaginary quantity.

Example of the 1ſt form, let $x^2 + 6x = 7$. Here then $a = 6$, and $b = 7$; then $x = -\frac{1}{2}a \pm \sqrt{\frac{1}{4}a^2 + b} = -3 \pm \sqrt{16} = -3 \pm 4 = +1$ or -7.

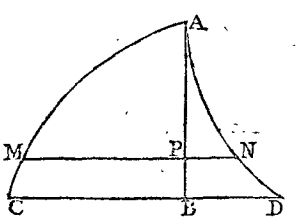
Example of the 2d form, let $x^2 - 6x = 7$. Here alſo $a = 6$, and $b = 7$; then $x = +\frac{1}{2}a \pm \sqrt{\frac{1}{4}a^2 + b} = +3 \pm \sqrt{16} = +3 \pm 4 = +7$ or -1; the ſame two roots as before, with the ſigns changed.

Example of the 3d form, let $x^2 - 6x = -7$. Here again $a = 6$, and $b = 7$; then $x = +\frac{1}{2}a \pm \sqrt{\frac{1}{4}a^2 - b} = +3 \pm \sqrt{2}$, the two roots both real.

But if $x^2 - 6x = -11$; then $a = 6$, and $b = 11$, which gives x or $+\frac{1}{2}a \pm \sqrt{\frac{1}{4}a^2 - b} = +3 \pm \sqrt{-2}$, the two roots both imaginary.

All equations whatever that have only two different powers of the unknown quantity, of which the index of the one is juſt double to that of the other, are reſolved like Quadratics, by completing the ſquare. Thus, the equation $x^4 + ax^2 = b$, by completing the ſquare becomes $x^4 + ax^2 + \frac{1}{4}a^2 = \frac{1}{4}a^2 + b$; whence, extracting the root on both ſides, $x^2 + \frac{1}{2}a = \pm\sqrt{\frac{1}{4}a^2 + b}$; therefore $x^2 = -\frac{1}{2}a \pm \sqrt{\frac{1}{4}a^2 + b}$, and conſequently $x = \pm\sqrt{-\frac{1}{2}a \pm \sqrt{\frac{1}{4}a^2 + b}}$, where the root x has four values, becauſe the given equation $x^4 + ax^2 = b$ riſes to the 4th power. See EQUATION.

QUADRATRIX, or QUADRATIX, in Geometry, is a mechanical line, by means of which, right lines are found equal to the circumference of circles, or other curves, and of the parts of the ſame. Or, more accurately, the *Quadratrix of a curve*, is a tranſcendental curve deſcribed on the ſame axis, the ordinates of which being given, the quadrature of the correſpondent parts in the other curve is likewiſe given. See CURVE.—Thus, for example, the curve AND may be



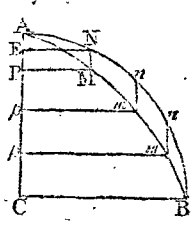
called the Quadratrix of the parabola AMC, when the area APMA bears ſome ſuch relation as the following to the abſciſs AP or ordinate PN, viz,

when $APM = PN^2$,
or $APM = AP \times PN$,
or $APM = a \times PN$,

where a is ſome given conſtant quantity.

The moſt diſtinguiſhed of theſe Quadratices are, thoſe of Dinoſtrates and of Tſchirnhauſen for the circle, and that of Mr. Perks for the hyperbola.

QUADRATRIX *of Dinoſtrates*, is a curve AMD, by which the quadrature of the circle is effected, though not geometrically, but only mechanically. It is ſo called from its inventor Dinoſtrates; and the geneſis or deſcription of it is as follows: Divide the quadrantal arc ANB into any number of equal parts, in the points N, *n*, *n*, &c; and alſo the radius AC into the ſame number of parts at the points P, *p*, *p*, &c. To the points of N, *n*, *n*, &c, draw the radii CN, C*n*, &c; and from the points P, *p*, &c, the parallels to CB, as PM, P*m*, &c: then through all the points of interſection draw the curve A*Mm*D, and it will be the Quadratrix of Dinoſtrates.



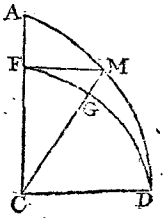
Or the ſame curve may be conceived as deſcribed by a continued motion, thus: Conceive a radius CN to revolve with a uniform motion about the centre C, from the poſition AC to the poſition BC; and at the ſame time a ruler PM always moving uniformly parallel towards CB; the two uniform motions being ſo regulated that the radius and the ruler ſhall arrive at the poſition BC at the ſame time. For thus the continual interſection M, *m*, &c. of the revolving radius, and moving ruler, will deſcribe the Quadratrix A*Mm* &c. Hence,

1. *For the Equation of the Quadratrix:* Since, from the relation of the uniform motions, it is always, AB : AN :: AC : AP; therefore if $AB = a$, $AC = r$, $AP = x$, and $AN = z$, it will be $a : z :: r : x$, or $ax = rz$, which is the equation of the curve.

Or, if s denote the ſine NE of the arc AN, and $y = PM$ the ordinate of the curve AM, its abſciſs AP being x; then, by ſimilar triangles, CE : CP :: EN : PM, that is, $\sqrt{r^2 - s^2} : r - x :: s : y$, and hence $y\sqrt{r^2 - s^2} = r - x \cdot s$, the equation of the curve. And when the relation between AB and AN is given, in terms of that between AC and AP, hence will be expreſſed the relation between the ſine EN and the radius CB, or s will be expreſſed in terms of r and x; and conſequently the equation of the curve will be expreſſed in terms of r, x, and y only.

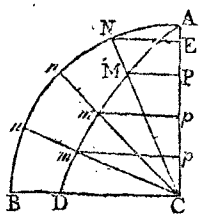
2. The baſe of the Quadratrix CD is a third proportional to the quadrant AB and the radius AC or CB; i. e. CD : CB :: CB : AB. Hence the rectification and quadrature of the circle.

3. A quadrantal arc DF deſcribed with the centre C and radius CD, will be equal in length to the radius CA or CB.



4. CDF being a quadrant inſcribed in the Quadratrix AMD, if the baſe CD be $= 1$, and the circular arc $DG = x$; then in the area $CFMD = x - \frac{1}{9}x^3 - \frac{1}{225}x^5 - \frac{2}{6615}x^7$ &c. See QUADRATURE.

QUADRATRIX *of Tschirnhausen*, is a tranſcendental curve AM*m*B by which the quadrature of the circle is likewiſe effected. This was invented by M. Tſchirnhauſen, and its geneſis, in imitation of that of Dinoſtrates, is as follows: Divide the quadrant ANC, and the radius AC, each into equal parts, as before; and from the points P, *p*, &c, draw the lines PM, *pm*, &c, parallel to CB; alſo from the points N, *n*, &c, the lines NM, *nm*, &c, parallel to the other radius AC; ſo ſhall all the interſections M, *m*, &c, be in the curve of the Quadratrix AM*m*B.



Now for the Equation of this Quadratrix; it is, as before, AB : AN :: AC : AP,

or $a : z :: r : x$, or $ax = rz$.

Or, becauſe here $y = \mathrm{PM} = \mathrm{EN} = s$; therefore s, as before, expreſſed in terms of r and x, gives the equation of this Quadratrix in terms of r, x, and y, and that in a ſimpler form than the other. Thus, from the nature of the circle and the conſtruction of the Quadratrix, it is

$$y \text{ or } s = x + \frac{r^2 - x^2}{2 \cdot 3r^2}A + \frac{3^2r^2 - x^2}{4 \cdot 5r^2}B + \frac{5^2r^2 - x^2}{6 \cdot 7r^2}C \text{ &c,}$$

where A, B, C, &c, are the preceding terms; which is the equation of the curve or Quadratrix of Tſchirnhauſen.

By either Quadratix, it is evident that an arc or angle is eaſily divided into three, or any other number of equal parts; viz, by dividing the correſponding radius, or part of it, into the ſame number of equal parts: for AN is always the ſame part of AB, that AP is of AC.

QUADRATURE, in Aſtronomy, that aſpect or poſition of the moon when ſhe is 90° diſtant from the ſun. Or, the Quadratures or quarters are the two middle points of the moon's orbit between the points of conjunction and oppoſition, viz, the points of the 1ſt and 3d quarters; at which times the moon's face ſhews half full, being dichotomized or biſected.

The moon's orbit is more convex in the Quadratures than in the ſyzygies, and the greater axis of her orbit paſſes through the Quadratures, at which points alſo ſhe is moſt diſtant from the earth.—In the Quadratures, and within 35° of them, the apſes of the moon go backwards, or move in antecedentia; but in the ſyzygies the contrary.—When the nodes are in the Quadratures, the inclination of the moon's orbit is greateſt, but leaſt when they are in the ſyzygies.

QUADRATURE *Lines*, or *Lines of* QUADRATURE, are two lines often placed on Gunter's ſector. They are marked with the letter Q, and the figures 5, 6, 7, 8, 9, 10; of which Q denotes the ſide of a ſquare, and the figures denote the ſides of polygons of 5, 6, 7, &c ſides. Alſo S denotes the ſemidiameter of a circle, and 90 a line equal to the quadrant or 90° in circumference.

QUADRATURE, in Geometry, is the ſquaring of a figure, or reducing it to an equal ſquare, or finding a ſquare equal to the area of it.

The Quadrature of rectilineal figures falls under common geometry, or menſuration; as amounting to no more than the finding their areas, or ſuperficies; which are in effect their ſquares: which was fully effected by Euclid.

The QUADRATURE *of Curves*, that is, the meaſuring of their areas, or the finding a rectilineal ſpace equal to a propoſed curvilineal one, is a matter of much deeper ſpeculation; and makes a part of the ſublime or higher geometry. The lunes of Hypocrates are the firſt curves that were ſquared, as far as we know of. The circle was attempted by Euclid and others before him: he ſhewed indeed the proportion of one circle to another, and gave a good method of approximating to the area of the circle, by deſcribing a polygon between any two concentric circles, however near their circumferences might be to each other. At this time the conic ſections were admitted in geometry, and Archimedes, perfectly, for the firſt time, ſquared the parabola, and he determined the relations of ſpheres, ſpheroids, and conoids, to cylinders and cones; and by purſuing the method of exhauſtions, or by means of inſcribed and circumſcribed polygons, he approximated to the periphery and area of the circle; ſhewing that the diameter is to the circumference nearly as 7 to 22, and the area of the circle to the ſquare of the diameter as 11 to 14 nearly. Archimedes likewiſe determined the relation between the circle and ellipſe, as well as that of their ſimilar parts: It is probable too that he attempted the hyperbola; but it is not likely that he met with any ſucceſs, ſince approximations to its area are all that can be given by the various methods that have ſince been invented. Beſide theſe figures, he left a treatiſe on a ſpiral curve; in which he determined the relation of its area to that of the circumſcribed circle; as alſo the relation of their ſectors.

Several other eminent men among the Ancients wrote upon this ſubject, both before and after Euclid and Archimedes; but their attempts were uſually confined to particular parts of it, and made according to methods not eſſentially different from theirs. Among theſe are to be reckoned Thales, Anaxagoras, Pythagoras, Bryſon, Antiphon, Hypocrates of Chios, Plato, Apollonius, Philo, and Ptolomy; moſt of whom wrote upon the Quadrature of the circle; and thoſe after Archimedes, by his method, uſually extended the approximation to a higher degree of accuracy.

Many of the Moderns have alſo proſecuted the ſame problem of the Quadrature of the circle, after the ſame methods, to ſtill greater lengths; ſuch are Vieta, and Metius; whoſe ratio between the diameter and the circumference, is that of 113 to 355, which is within about $\frac{3}{10000000}$ of the true ratio; but above all, Ludolph van Collen, or a Ceulen, who, with an amazing degree of induſtry and patience, by the ſame methods, extended the ratio to 36 places of figures, making the ratio to be that of

1 to 3·14159,26535,89793,23846,26433,83279.50288 + or 9 —. And the ſame was repeated and confirmed by his editor Snellius. See DIAMETER, and CIRCLE; alſo the Preface to my Menſuration.

Though the Quadrature, eſpecially of the circle, be a thing which many of the principal mathematicians, among the Ancients, were very ſolicitous about; yet nothing of this kind has been done ſo conſiderable, as

about

about and ſince the middle of the laſt century; when, for example, in the year 1657, Sir Paul Neil, Lord Brouncker, and Sir Chriſtopher Wren geometrically demonſtrated the equality of ſome curvilineal ſpaces to rectilineal ones. Soon after this, other perſons did the like in other curves; and not long afterwards the thing was brought under an analytical calculus, the firſt ſpecimen of which ever publiſhed, was given by Mercator in 1688, in a demonſtration of Lord Brouncker's Quadrature of the hyperbola, by Dr. Wallis's method of reducing an algebraical fraction into an infinite ſeries by diviſion.

Though, by the way, it appears that Sir Iſaac Newton had diſcovered a method of attaining the area of all quadrable curves analytically, by his Method of Fluxions, before the year 1668. See his *Fluxions*, alſo his *Analyſis per Æquationes Numero Terminorum Infinitas*, and his *Introductio ad Quadraturam Curvarum*; where the Quadratures of Curves are given by general methods.

It is conteſted, between Mr. Huygens and Sir Chriſtopher Wren, which of the two firſt found out the Quadrature of any determinate cycloidal ſpace. Mr. Leibnitz afterwards diſcovered that of another ſpace; and Mr. Bernoulli, in 1699, found out the Quadrature of an infinity of cycloidal ſpaces, both ſegments and ſectors &c.

As to the Quadrature of the Circle in particular, or the finding a ſquare equal to a given circle, it is a problem that has employed the mathematicians of all ages, but ſtill without the deſired ſucceſs. This depends on the ratio of the diameter to the circumference, which has never yet been determined in preciſe numbers. Many perſons have approached very near this ratio; for which ſee CIRCLE.

Strict geometry here failing, mathematicians have had recourſe to other means, and particularly to a ſort of curves called quadratices: but theſe being mechanical curves, inſtead of geometrical ones, or rather tranſcendental inſtead of algebraical ones, the problem cannot fairly be effected by them.

Hence recourſe has been had to analytics. And the problem has been attempted by three kinds of algebraical calculations. The firſt of theſe gives a kind of tranſcendental Quadratures, by equations of indefinite degrees. The ſecond by vulgar numbers, though irrationally ſuch; or by the roots of common equations, which for the general Quadrature is impoſſible. The third by means of certain ſeries, exhibiting the quantity of a circle by a progreſſion of terms. See SERIES.

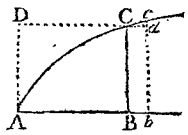
Thus, for example, the diameter of a circle being 1, it has been found that the quadrant, or one-fourth of the circumference, is equal to $\frac{1}{1}-\frac{1}{3}+\frac{1}{5}-\frac{1}{7}+\frac{1}{9}$ &c, making an infinite ſeries of fractions, whoſe common numerator is 1, and denominators the natural ſeries of odd numbers; and all theſe terms alternately will be too great, and too little. This ſeries was diſcovered by Leibnitz and Gregory. And the ſame ſeries is alſo the area of the circle.

If the ſum of this ſeries could be found, it would give the Quadrature of the circle: but this is not yet done; nor is it at all probable that it ever will be done; though the impoſſibility has never yet been demonſtrated.

To this it may be added, that as the ſame magnitude may be expreſſed by ſeveral different ſeries, poſſibly the circumference of the circle may be expreſſed by ſome other ſeries, whoſe ſum may be found. And there are many other ſeries, by which the quadrant, or area, to the diameter, has been expreſſed; though it has never been found that any one of them is actually ſummable. Such as this ſeries, $1-\frac{1}{6}-\frac{1}{40}-\frac{1}{112}$ &c, invented by Newton; with innumerable others.

But though a definite Quadrature of the whole circle was never yet given, nor of any aliquot part of it; yet certain other portions of it have been ſquared. The firſt partial Quadrature was given by Hippocrates of Chios; who ſquared a portion called, from its figure, the *lune*, or *lunule*; but this Quadrature has no dependence on that of the circle. And ſome modern geometricians have found out the Quadrature of any portion of the lune taken at pleaſure, independently of the Quadrature of the circle; though ſtill ſubject to a certain reſtriction, which prevents the Quadrature from being perfect, and what the geometricians call abſolute and indefinite. See LUNE. And for the Quadrature of the different kinds of curves, ſee their ſeveral particular names.

QUADRATURES *by Fluxions*.—The moſt general method of Quadratures yet diſcovered, is that of Newton, by means of Fluxions, and is as follows. AC being any curve to be ſquared, AB an abſciſs, and BC an ordinate perpendicular to it, alſo *bc* another ordinate indefinitely near to the former. Putting AB $= x$, and BC $= y$;



then is B*b* $= \dot{x}$ the fluxion of the abſciſs, and $y\dot{x}$ = C*b* the fluxion of the area ABC ſought. Now let the value of the ordinate y be found in terms of the abſciſs x, or in a function of the abſciſs, and let that function be called X, that is $y = X$; then ſubſtituting X for y in $y\dot{x}$, gives $X\dot{x}$ the fluxion of the area; and the fluent of this, being taken, gives the area or Quadrature of ABC as required, for any curve, whatever its nature may be.

Ex. Suppoſe for example, AC to be a common parabola; then its equation is $px = y^2$, where p is the parameter; which gives $y = \sqrt{px}$, the value of y in a function of x, and is what is called X above; hence then $y\dot{x} = \dot{x}\sqrt{px} = p^{\frac{1}{2}}x^{\frac{1}{2}}\dot{x}$ is the fluxion of the area; and the fluent of this is $\frac{2}{3}p^{\frac{1}{2}}x^{\frac{3}{2}} = \frac{2}{3}x\sqrt{px} = \frac{2}{3}xy = \frac{2}{3}$ of the circumſcribing rectangle BD; which therefore is the Quadrature of the parabola.

Again, if AC be a circle whoſe diameter is d; then its equation is $y^2 = dx - x^2$, which gives $y = \sqrt{dx - x^2}$, and the fluxion of the area $y\dot{x} = \dot{x}\sqrt{dx - x^2}$. But as the fluent of this cannot be found in finite terms, the quantity $\sqrt{dx - x^2}$ is thrown into a ſeries, and then the fluxion of the area

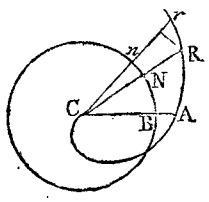
is

is $y\dot{x} = \dot{x}\sqrt{dx - x^2} = \dot{x}\sqrt{dx} \times (1 - \frac{x}{2d} - \frac{x^2}{2.4d^2} - \frac{1.3x^3}{2.4.6d^3}$ &c) $=$ and the fluent of this gives

$$x\sqrt{dx} \times (\frac{2}{3} - \frac{1}{5}\cdot\frac{x}{d} - \frac{1}{4.7}\cdot\frac{x^2}{d^2} - \frac{1.3}{4.6.9}\cdot\frac{x^3}{d^3}\ \&c).$$

for the general expreſſion of the area ABC. Now when the ſpace becomes a ſemicircle, x becomes $= d$, and then the ſeries above becomes $d^2(\frac{2}{3} - \frac{1}{5} - \frac{1}{4.7} - \frac{1.3}{4.6.9}$ &c) for the area of the ſemicircle whoſe diameter is d.

In ſpirals CAR, or curves referred to a centre C; put $y =$ any radius CR, $x =$ BN the arc of a circle deſcribed about the centre C, at any diſtance CB $= a$, and Cnr another ray indefinitely near CNR: then $\frac{1}{2}$ CN . Nn $=$



$\frac{1}{2}\ a\dot{x} =$ CNn, and by ſim. fig. CN^2 : CR^2 or $a^2 : y^2$ :: CNn : $\frac{y^2\dot{x}}{2a} =$ CRr the fluxion of the area deſcribed by the revolving ray CR; then the fluent of this, for any particular caſe, will be the Quadrature of the ſpiral. So if, for inſtance, it be Archimedes's ſpiral, in which $x : y$ in a conſtant ratio ſuppoſe as $m : n$, or $my = nx$, and $y^2 = \frac{n^2x^2}{m^2}$; hence then CRr $= \frac{y^2\dot{x}}{2a} = \frac{n^2x^2\dot{x}}{2am^2}$ the fluxion of the area; the fluent of which is $\frac{n^2x^3}{6am^2} = \frac{xy^2}{6a}$ the general Quadrature of the ſpiral of Archimedes.

QUADRILATERAL, or QUADRILATERAL *Figure*, is a figure comprehended by four right lines; and having conſequently alſo four angles, for which reaſon it is otherwiſe called a quadrangle.

The general term Quadrilateral comprehends theſe ſeveral particular ſpecies or figures, viz, the ſquare, parallelogram, rectangle, rhombus, rhomboides, and trapezium.

If the oppoſite ſides be parallel, the Quadrilateral is a parallelogram. If the parallelogram have its angles right ones, it is a rectangle; if oblique, it is an oblique one. The rectangle having all its ſides equal, becomes a ſquare; and the oblique parallelogram having all its ſides equal, is a rhombus, but if only the oppoſites be equal, it is a rhomboides. All other forms of the Quadrilateral, are trapeziums, including all the irregular ſhapes of it.

The ſum of all the four angles of any Quadrilateral, is equal to 4 right angles. Alſo, the two oppoſite angles of a Quadrilateral inſcribed in a circle taken together, are equal to two right angles. And in this caſe the rectangle of the two diagonals, is equal to the ſum of the two rectangles of the oppoſite ſides. For the properties of the particular ſpecies of Quadrilaterals, ſee their reſpective names, SQUARE, RECTANGLE, PARALLELOGRAM, RHOMBUS, RHOMBOIDES, and TRAPEZIUM.

QUADRIPARTITION, is the dividing by 4, or into four equal parts.—Hence *quadripartite*, &c, the 4th part, or ſomething parted into four.

QUADRUPLE, is four-fold, or ſomething taken four times, or multiplied by 4; and ſo is the converſe of Quadripartition.

QUALITY, denotes generally the property or affection of ſome being, by which it affects our ſenſes in a certain way, &c.

Senſible Qualities are ſuch as are the more immediate object of the ſenſes: as figure, taſte, colour, ſmell, hardneſs, &c.

Occult Qualities, among the Ancients, were ſuch as did not admit of a rational ſolution in their way.

Dr. Keil demonſtrates, that every Quality which is propagated in orbem, ſuch as light, heat, cold, odour, &c, has its efficacy or intenſity either increaſed, or decreaſed, in a duplicate ratio of the diſtances from the centre of radiation inverſely. So at double the diſtance from the earth's centre, or from a luminous or hot body, the weight or light or heat, is but a 4th part; and at 3 times the diſtance, they are 9 times leſs, or a 9th part, &c.

Sir Iſaac Newton lays it down as one of the rules of philoſophizing, that thoſe Qualities of bodies that are incapable of being intended and remitted, and which are found to obtain in all bodies upon which the experiment could ever be tried, are to be eſteemed univerſal Qualities of all bodies.

QUALITY *of Curvature*, in the higher geometry, is uſed to ſignify its form, as it is more or leſs inequable, or as it is varied more or leſs in its progreſs through different parts of the curve. Newton's Method of Fluxions, pa. 75; and Maclaurin's Fluxions, art. 369.

QUANTITY, denotes any thing capable of eſtimation, or menſuration; or which being compared with another thing of the ſame kind, may be ſaid to be either greater or leſs, equal or unequal to it.

Mathematics is the doctrine or ſcience of Quantity.

Phyſical or *Natural* QUANTITY, is of two kinds: 1ſt, that which nature exhibits in matter, and its extenſion; and 2dly, in the powers and properties of natural bodies; as gravity, motion, light, heat, cold, denſity, &c.

Quantity is popularly diſtinguiſhed into continued and diſcrete.

Continued QUANTITY, is when the parts are connected together, and is commonly called magnitude; which is the object of geometry.

Diſcrete QUANTITY, is when the parts, of which it conſiſts, exiſt diſtinctly, and unconnected; which makes what is called multitude or number, the object of arithmetic.

The notion of continued Quantity, and its difference from diſcrete, appears to ſome without foundation. Mr. Machin conſiders all mathematical Quantity, or that for which any ſymbol is put, as nothing elſe but number, with regard to ſome meaſure, which is conſidered as 1; for that we know nothing preciſely how much any thing is, but by means of number. The notion of continued Quantity, without regard to ſome meaſure, is indiſtinct and confuſed; and though ſome ſpecies of ſuch Quantity, conſidered phyſically, may be deſcribed by motion, as lines by the motion of

points,

points, and ſurfaces by the motion of lines; yet the magnitudes, or mathematical Quantities, are not made by the motion, but by numbering according to a meaſure. Philoſ. Tranſ. numb. 447, pa. 228.

QUANTITY *of Action*. See ACTION.

QUANTITY *of Curvature* at any point of a curve is determined by the circle of curvature at that point, and is reciprocally proportional to the radius of curvature.

QUANTITY *of Matter* in any body, is its meaſure ariſing from the joint conſideration of its magnitude and denſity, being expreſſed by, or proportional to the product of the two. So,

if M and *m* denote the magnitude of two bodies,
and D and *d* their denſities;
then DM and *dm* will be as their Quantities of matter.

The Quantity of matter of a body is beſt diſcovered by its abſolute weight, to which it is always proportional, and by which it is meaſured.

QUANTITY *of Motion*, or the *Momentum*, of any body, is its meaſure ariſing from the joint conſideration of its Quantity, and the velocity with which it moves. So,

if *q* denote the Quantity of matter,
and *v* the velocity of any body;
then *qv* will be its quantity of motion.

QUANTITIES, in Algebra, are the expreſſions of indefinite numbers, that are uſually repreſented by letters. Quantities are properly the ſubject of Algebra; which is wholly converſant in the computation of ſuch Quantities.

Algebraic Quantities are either *given* and *known*, or elſe they are *unknown* and *ſought*. The given or known Quantities are repreſented by the firſt letters of the alphabet, as *a*, *b*, *c*, *d*, *e*, &c, and the unknown or required Quantities, by the laſt letters, as *z*, *y*, *x*, *w*, &c.

Again, Algebraic Quantities are either poſitive or negative.

A poſitive or affirmative Quantity, is one that is to be added, and has the ſign + or plus prefixed, or underſtood; as *ab* or + *ab*. And a negative or privative Quantity, is one that is to be ſubtracted, and has the ſign — or minus prefixed; as — *ab*.

QUART, a meaſure of capacity, being the quarter or 4th part of ſome other meaſure. The Engliſh Quart is the 4th part of the gallon, and contains two pints. The Roman Quart, or quartarius, was the 4th part of their congius. The French, beſides their Quart or pot of 2 pints, have various other Quarts, diſtinguiſhed by the whole of which they are Quarters; as, Quart de muid, and Quart de boiſſeau.

QUARTER, the 4th part of a whole, or one part of an integer, which is divided into four equal portions.

QUARTER, in weights, is the 4th part of the quintal, or hundred weight; and ſo contains 28 pounds.

QUARTER is alſo a dry meaſure, containing of corn 8 buſhels ſtriked; and of coals the 4th part of a chaldron.

Quarter, in Aſtronomy, the moon's period, or lunation, is divided into 4 ſtages or Quarters; each containing between 7 and 8 days. The firſt Quarter is from the new moon to the quadrature; the ſecond is from thence to the full moon, and ſo on.

QUARTER, in Navigation, is the Quarter or 4th part of a point, wind, or rhumb; or of the diſtance between two points &c. The Quarter contains an arch of 2° 48′ 45″, being the 4th part of 11° 15′, which is one point.

QUARTER *Round*, in Architecture, is a term uſed by the workmen for any projecting moulding, whoſe contour is a Quarter of a circle, or nearly ſo.

QUARTILE, an aſpect of the planets when they are at the diſtance of 3 ſigns or 90° from each other: and is denoted by the character □.

QUEUE D'ARONDE, or *Swallow's Tail*, in Fortification, is a detached or outwork, whoſe ſides ſpread or open towards the campaign, or draw narrower and cloſer towards the gorge. Of this kind are either ſingle or double tenailles, and ſome horn-works, whoſe ſides are not parallel, but are narrow at the gorge, and open at the head, like the figure of a ſwallow's tail.

On the contrary, when the ſides are leſs than the gorge, the work is called *contre Queue d'aronde*.

QUEUE *d'aronde*, in Carpentry, a method of jointing, called alſo dove-tailing.

QUINCUNX, denotes $\frac{5}{12}$ths of any thing. So 10 is quincunx of 24, being $\frac{5}{12}$ of it.

QUINCUNX, in Aſtronomy, is that poſition, or aſpect, of the planets, when diſtant from each other by $\frac{5}{12}$ths of the whole circle, or 5 ſigns out of the 12, that is 150 degrees. The Quincunx is marked Q, or Vc.

QUINDECAGON, is a plane figure of 15 angles, and conſequently the ſame number of ſides. When thoſe are all equal, it is a regular Quindecagon, otherwiſe not.

Euclid ſhews how to inſcribe this figure in a circle, prop. 16, lib. 4. And the ſide of a regular Quindecagon, ſo inſcribed, is equal in power to the half difference between the ſide of the equilateral triangle, and the ſide of the pentagon; and alſo to the difference of the perpendiculars let fall on both ſides, taken together.

QUINQUAGESIMA-*Sunday*, is the ſame as Shrove-Sunday, and is ſo called as being about the 50th day before Eaſter, being indeed the 7th Sunday before it. Anciently the term Quinquageſima was uſed for Whitſunday, and for the 50 days between Eaſter and Whitſunday; but to diſtinguiſh this Quinquageſima from that before Eaſter, it was called the paſchal Quinquageſima.

QUINQUEANGLED, or Quinqueangular, conſiſting of 5 angles.

QUINTAL, the weight of a hundred pounds, in moſt countries; but in England it is the hundred weight, or 112 pounds. Quintal was alſo formerly uſed for a weight of lead, iron, or other common metal, uſually equal to a hundred pounds, at 6 ſcore to the hundred.

QUINTILE, in Aſtronomy, an aſpect of the planets when they are diſtant the 5th part of the zodiac, or 72 degrees; and is marked thus, C, or O.

QUINTUPLE, is five-fold, or five times as much as another thing.

QUOIN, in Architecture, an angle or corner of ſtone or brick walls. When theſe ſtand out beyond the reſt of the wall, their edges being chamferred off, they are called *ruſtic Quoins*.

QUOIN, in Artillery, is a looſe wedge of wood, which

is put in below the breech of a cannon, to raiſe or depreſs it more or leſs.

QUOTIENT, in Arithmetic, is the reſult of the operation of diviſion, or the number that ariſes by dividing the dividend by the diviſor, ſhewing how often the latter is contained in the former. Thus the Quotient of 12 divided by 3 is 4; which is uſually thus diſpoſed, or expreſſed,

3) 12 (4 the quotient,

or thus $12 \div 3 = 4$ the Quotient, or thus $\frac{12}{3}$ like a vulgar fraction; all theſe meaning the ſame thing.—In diviſion, as the diviſor is to the dividend, ſo is unity or 1 to the Quotient; thus 3 : 12 :: 1 : 4 the Quotient.

R.

RAD

RADIANT *Point*, or RADIATING *Point*, is any point from whence rays proceed.

Every Radiant point diffuſes innumerable rays all around: but thoſe rays only are viſible from which right lines can be drawn to the pupil of the eye; becauſe the rays are all in right lines. All the rays proceeding from the ſame Radiant continually diverge; but the cryſtalline collects or reunites them again.

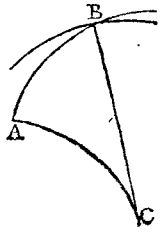
RADIATION, is the caſting or ſhooting forth of rays of light as from a centre.—Every viſible body is a radiating body; it being only by means of its rays that it affects the eye.—The ſurface of a radiating or viſible body, may be conceived as conſiſting of radiant points.

RADICAL *Sign*, in Algebra, the ſign or character denoting the root of a quantity; and is this $\surd$. So $\surd 2$ is the ſquare root of 2, and $\sqrt[3]{2}$ is the cube root of 2, &c.

RADIOMETER, a name which ſome writers give to the Radius Aſtronomicus, or Jacob's Staff. See FORE-STAFF.

RADIUS, in Geometry, the ſemidiameter of a circle; or a right line drawn from the centre to the circumference.—It is implied in the definition of a circle, and it is apparent from its conſtruction, that all the radii of the ſame circle are equal.—The Radius is ſometimes called, in Trigonometry, the Sinus Totus, or whole ſine.

RADIUS, in the Higher Geometry. RADIUS *of the Evoluta*, RADIUS *Oſculi*, called alſo the *Radius of concavity*, and the *Radius of curvature*, is the right line CB, repreſenting a thread, by whoſe evolution from off the curve AC, upon which it was wound, the curve AB is formed. Or it is the Radius of a circle having the ſame curvature, in a given point of the curve at B, with that of the curve in that point. See CURVATURE and EVOLUTE, where the method of finding this Radius may be ſeen.



RAF

RADIUS *Aſtronomicus*, an inſtrument uſually called Jacob's Staff, the Croſs-ſtaff, or Fore-ſtaff.

RADIUS, in Mechanics, is applied to the ſpokes of a wheel; becauſe iſſuing like rays from its centre.

RADIUS, in Optics. See RAY.

RADIUS *Vector*, is uſed for a right line drawn from the centre of force in any curve in which a body is ſuppoſed to move by a centripetal force, to that point of the curve where the body is ſuppoſed to be.

RADIX, or *Root*, is a certain finite expreſſion or function, which, being evolved or expanded according to the rules proper to its form, ſhall produce a ſeries. That finite expreſſion, or Radix, is alſo the value of the infinite ſeries. So $\frac{1}{3}$ is the radix of ·3333 &c, becauſe $\frac{1}{3}$ being evolved or expanded, by dividing 1 by 3, gives the infinite ſeries ·3333 &c. In like manner, the Radix

of $1 - r + r^2 - r^3 + r^4$ &c is $\frac{1}{1+r}$,

of $1 - \frac{1}{2} + \frac{1}{4} - \frac{1}{8} + \frac{1}{16}$ &c is $\frac{1}{1+\frac{1}{2}}$,

of $1 - 1 + 1 - 1 + 1$ &c is $\frac{1}{1+1}$,

of $1 - 2 + 4 - 8 + 16$ &c is $\frac{1}{1+2}$,

of $\frac{1}{2} - \frac{1}{4} + \frac{1}{8} - \frac{1}{16} + \frac{1}{32}$ &c is $\frac{1}{2+1}$,

of $1 + x + x^2 + x^3 + x^4$ &c is $\frac{1}{1+x}$,

of $1 + 2x + 3x^2 + 4x^3$ &c is $\frac{1}{(1-x)^2}$,

of $1 + \frac{x^2}{2} + \frac{3x^4}{8} + \frac{5x^6}{16}$ &c is $\frac{1}{1-x^2}$.

See my Tracts, vol. 1, pa. 9, and 31, &c.

RAFTERS, in Architecture, are pieces of timber which ſtand by pairs on the raiſing-piece, or wall plate, and meet in an angle at the top, forming the roof of a building.

RAIN, water that deſcends from the atmoſphere in the form of drops of a conſiderable ſize. Rain is apparently a precipitated cloud; as clouds are nothing but vapours raiſed from moiſture, waters, &c. By this circumſtance it is diſtinguiſhed from dew and fog: in the former of which the drops are ſo ſmall that they are quite inviſible; and in the latter, though their ſize be larger, they ſeem to have very little more ſpecific gravity than the atmoſphere itſelf, and may therefore be reckoned hollow ſpherules rather than drops.

It is univerſally agreed, that Rain is produced by the water previouſly abſorbed by the heat of the ſun, or otherwiſe, from the terraqueous globe, into the atmoſphere, as vapours, or veſiculæ. Theſe veſiculæ, being ſpecifically lighter than the atmoſphere, are buoyed up by it, till they arrive at a region where the air is in a juſt balance with them; and there they float, till by ſome new agent they are converted into clouds, and thence either into Rain, ſnow, hail, miſt, or the like.

But the agent in this formation of the clouds into Rain, and even of the vapours into clouds, has been much controverted. Moſt philoſophers will have it, that the cold, which conſtantly occupies the ſuperior regions of the air, chills and condenſes the veſiculæ, at their arrival from a warmer quarter; congregates them together, and occaſions ſeveral of them to coaleſce into little maſſes: and thus their quantity of matter increaſing in a higher proportion than their ſurface, they become an overload to the thin air, and ſo deſcend in Rain.

Dr. Derham accounts for the precipitation, hence; that the veſiculæ being full of air, when they meet with a colder air than that they contain, this is contracted into a leſs ſpace: and conſequently the watry ſhell or caſe becomes thicker, ſo as to become heavier than the air, &c.

But this ſeparation cannot be aſcribed to cold, ſince Rain often takes place in very warm weather. And though we ſhould ſuppoſe the condenſation owing to the cold of the higher regions, yet there is a remarkable fact which will not allow us to have recourſe to this ſuppoſition: for it is certain that the drops of Rain increaſe in ſize conſiderably as they deſcend. On the top of a hill for inſtance, they will be ſmall and inconſiderable, forming only a drizzling ſhower; but half way down the hill it is much more conſiderable; and at the bottom the drops will be very large, deſcending in an impetuous Rain. Which ſhews that the atmoſphere condenſes the vapours as well where it is warm as where it is cold.

Others allow the cold only a part in the action, and bring in the winds as ſharers with it: alledging, that a wind blowing againſt a cloud will drive its veſiculæ upon one another, by which means ſeveral of them, coaleſcing as before, will be enabled to deſcend; and that the effect will be ſtill more conſiderable, if two oppoſite winds blow together towards the ſame place: they add, that clouds already formed, happening to be aggregated by freſh acceſſions of vapour continually aſcending, may thence be enabled to deſcend.

Yet the grand cauſe, according to Rohault, is ſtill behind. That author conceives it to be the heat of the air, which, after continuing for ſome time near the earth, is at length carried up on high by a wind, and there thawing the ſnowy villi or flocks of the half frozen veſiculæ, it reduces them into drops; which, coaleſcing, deſcend, and have their diſſolution perfected in their progreſs through the lower and warmer ſtages of the atmoſphere.

Others, as Dr. Clarke, &c, aſcribe this deſcent of the clouds rather to an alteration of the atmoſphere than of the veſiculæ; and ſuppoſe it to ariſe from a diminution of the ſpring or elaſtic force of the air. This elaſticity, which depends chiefly or wholly on the dry terrene exhalations, being weakened, the atmoſphere ſinks under its burden; and the clouds fall, on the common principle of precipitation.

Now the ſmall veſiculæ, by theſe or any other cauſes, being once upon the deſcent, will continue to deſcend notwithſtanding the increaſe of reſiſtance they every moment meet with in their progreſs through ſtill denſer and denſer parts of the atmoſphere. For as they all tend toward the ſame point, viz, the centre of the earth, the farther they fall, the more coalitions will they make; and the more coalitions, the more matter will there be under the ſame ſurface; the ſurface only increaſing as the ſquares, but the ſolidity as the cubes of the diameters: and the more matter under the ſame ſurface, the leſs friction or reſiſtance there will be to the ſame matter.

Thus then, if the cauſes of rain happen to act early enough to precipitate the aſcending veſiculæ, before they are arrived at any conſiderable height, the coalitions being few in ſo ſhort a deſcent, the drops will be proportionably ſmall; thus forming what is called dew. If the vapours prove more copious, and riſe a little higher, there is produced a miſt or fog. A little higher ſtill, and they produce a ſmall rain, &c. If they neither meet with cold nor wind enough to condenſe or diſſipate them; they form a heavy, thick, dark ſky, which laſts ſometimes ſeveral days, or even weeks.

But later writers on this part of philoſophical ſcience have, with greater ſhew of truth, conſidered Rain as an electrical phenomenon. Signior Beccaria reckons Rain, hail, and ſnow, among the effects of a moderate electricity in the atmoſphere. Clouds that bring Rain, he thinks are produced in the ſame manner as thunder clouds, only by a moderate electricity. He deſcribes them at large; and the reſemblance which all their phenomena bear to thoſe of thunder clouds, is very ſtriking. He notes ſeveral circumſtances attending Rain without lightning, which render it probable that it is produced by the ſame cauſe as when it is accompanied with lightning. Light has been ſeen among the clouds by night in rainy weather; and even by day rainy clouds are ſometimes ſeen to have a brightneſs evidently independent of the ſun. The uniformity with which the clouds are ſpread, and with which the Rain falls, he thinks are evidences of an uniform cauſe like that of electricity. The intenſity alſo of electricity in his apparatus, uſually correſponded very nearly to the quantity of Rain that fell in the ſame time. Sometimes all the phenomena of thunder, lightning, hail, Rain, ſnow, and wind, have been obſerved at one time; which ſhews the connection they all have with ſome common cauſe. Signior Beccaria therefore ſuppoſes that, previous to Rain, a quantity of electric

matter eſcapes out of the earth, in ſome place where there is a redundancy of it; and in its aſcent to the higher regions of the air, collects and conducts into its path a great quantity of vapours. The ſame cauſe that collects, will condenſe them more and more; till, in the places of the neareſt intervals, they come almoſt into contact, ſo as to form ſmall drops; which, uniting with others as they fall, come down in the form of Rain. The Rain will be heavier in proportion as the electricity is more vigorous, and the cloud approaches more nearly to a thunder cloud; &c. See *Lettere dell Elettricifmo*; and Prieſtley's Hiſt. &c of Electricity, vol. 1, pa. 427, &c, 8vo. And for farther accounts of the phenomena of Rain &c, ſee BAROMETER, EVAPORATION, OMBROMETER, PLUVIAMETER, VAPOUR, &c. See alſo the Theory of Rain, by Dr. James Hutton, art. 2 vol. 1 of Tranſactions of the Royal Society of Edinburgh.

Quantity of RAIN. As to the general quantity of Rain that falls, with its proportion in ſeveral places at the ſame time, and in the ſame place at different times, there are many obſervations, journals, &c, in the Philoſ. Tranſ. the Memoirs of the French Academy, &c. And upon meaſuring the rain that falls annually, its depth, on a medium, is found as in the following table:

Mean Annual Depth of Rain for ſeveral Places.

At	*Obſerved by*	*Inch.*
Townley, in Lancaſhire	Mr. Townley - -	42½

See alſo Philoſ. Tranſ. Abr. vol. 4, pt. 2, pa. 81, &c; and vol. 10 in many places; alſo the Meteorological Journal of the Royal Society, publiſhed annually in the Philoſ. Tranſ. and the article PLUVIAMETER or OMBROMETER.

It is reaſonably to be expected, and all experience ſhews, that the moſt Rain falls in places near the ſea coaſt, and leſs and leſs as the places are ſituated more inland. Some differences alſo ariſe from the circumſtances of hills, valleys, &c. So when the quantity of Rain fallen in one year at London, is 20 inches, that on the weſtern coaſt of England will often be twice as much, or 40 inches, or more. Thoſe winds alſo bring moſt Rain, that blow from the quarter in which is the moſt and neareſt ſea; as our weſt and ſouth-weſt winds.

It is alſo found, by the pluviameter or Rain-gage, that, in any one place, the more Rain is collected in the inſtrument, as it is placed nearer the ground; without any appearance of a difference, between two places, on account of their difference of level above the ſea, provided the inſtrument is but as far from the ground at the one place, as it is from the ground at the other. Theſe effects are remarked in the Philoſ. Tranſ. for 1769 and 1771, the former by Dr. Heberden, and the latter by Mr. Daines Barrington. Dr. Heberden ſays, "A compariſon having been made between the quantity of Rain, which fell in two places in London, about a mile diſtant from one another, it was found, that the Rain in one of them conſtantly exceeded that in the other, not only every month, but almoſt every time that it rained. The apparatus uſed in each of them was very exact, and both made by the ſame artiſt; and upon examining every probable cauſe, this unexpected variation did not appear to be owing to any miſtake, but to the conſtant effect of ſome circumſtance, which not being ſuppoſed to be of any moment, had never been attended to. The Rain-gage in one of theſe places was fixed ſo high, as to riſe above all the neighbouring chimnies; the other was conſiderably below them; and there appeared reaſon to believe, that the difference of the quantity of Rain in theſe two places was owing to this difference in the placing of the veſſel in which it was received. A funnel was therefore placed above the higheſt chimnies, and another upon the ground of the garden belonging to the ſame houſe, and there was found the ſame difference between theſe two, though placed ſo near one another, which there had been between them, when placed at ſimilar heights in different parts of the town. After this fact was ſufficiently aſcertained, it was thought proper to try whether the difference would be greater at a much greater height; and a Rain-gage was therefore placed upon the ſquare part of the roof of Weſtminſter Abbey. Here the quantity of Rain was obſerved for a twelvemonth, the Rain being meaſured at the end of every month, and care being taken that none ſhould evaporate by paſſing a very long tube of the funnel into a bottle through a cork, to which it was exactly fitted. The tube went down very near to the bottom of the bottle, and therefore the Rain which fell into it would ſoon riſe above the end of the tube, ſo that the water was no where open to the air except for

for the ſmall ſpace of the area of the tube: and by trial it was found that there was no ſenſible evaporation through the tube thus fitted up.

The following table ſhews the reſult of theſe obſervations.

From July the 7th 1766, to July the 7th 1767, there fell in a Rain-gage, fixed

1766.	Below the top of a houſe.	Upon the top of a houſe.	Upon Weſtminſter Abbey.
From the 7th to the end of July	*Inches.* 3·591	*Inches.* 3·210	*Inches.* 2·311
Auguſt	0·558	0·479	0·508
September	0·421	0·344	
October	2·364	2·061	1·416
November	1·079	0·842	0·632
December	1·612	1·258	0·994
1767, January	2·071	1·455	1·035
February	2·864	2·494	1·335
March	1·807	1·303	0·587
April	1·437	1·213	0·994
May	2·432	1·745	1·142
June	1·997	1·426	1·145
July 7	0·395	0·309	
	22·608	18·139	12·099

By this table it appears, that there fell below the top of a houſe above a fifth part more Rain, than what fell in the ſame ſpace above the top of the ſame houſe; and that there fell upon Weſtminſter Abbey not much above one half of what was found to fall in the ſame ſpace below the tops of the houſes. This experiment has been repeated in other places with the ſame reſult. What may be the cauſe of this extraordinary difference, has not yet been diſcovered; but it may be uſeful to give notice of it, in order to prevent that error, which would frequently be committed in comparing the Rain of two places without attending to this circumſtance."

Such were the obſervations of Dr. Heberden on firſt announcing this circumſtance, viz, of different quantities of Rain falling at different heights above the ground. Two years afterward, Daines Barrington Eſq. made the following experiments and obſervations, to ſhew that this effect, with reſpect to different places, reſpected only the ſeveral heights of the inſtrument above the ground at thoſe places, without regard to any real difference of level in the ground at thoſe places.

Mr. Barrington cauſed two other Rain-gages, exactly like thoſe of Dr. Heberden, to be placed, the one upon mount Rennig, in Wales, and the other on the plane below, at about half a mile's diſtance, the perpendicular height of the mountain being 450 yards, or 1350 feet; each gage being at the ſame height above the ſurface of the ground at the two ſtations.

The reſults of the Experiment are as below:

1770.	Bottom of the mountain.	Top of the mountain.
	Inches.	*Inches.*
From July 6 to 16	0·709	0·648
July 16 to 29	2·185	2·124
July 29 to Aug. 10.	0·610	0·656
Sept. 9 both bottles had run over.		
Sept. 9 to 30	3·234	2·464
Oct. 17. both bottles had run over.		
Oct. 17 to 22	0·747	0·885
Oct. 22 to 29	1·281	1·388
Nov. 20 both bottles were broken by the froſt	8·766	8·165

"The inference to be drawn from theſe experiments, Mr. Barrington obſerves, ſeems to be, that the increaſe of the quantity of Rain depends upon its nearer approximation to the earth, and ſcarcely at all upon the height of places, provided the Rain-gages are fixed at about the ſame diſtance from the ground.

"Poſſibly alſo a much controverted point between the inhabitants of mountains and plains may receive a ſolution from theſe experiments; as in an *adjacent valley, at leaſt*, very nearly the ſame quantity of Rain appears to fall within the ſame period of time as upon the neighbouring mountains."

Dr. Heberden alſo adds the following note. "It may not be improper to ſubjoin to the foregoing account, that, in places where it was firſt obſerved, a different quantity of Rain would be collected, according as the Rain-gages were placed above or below the tops of the neighbouring buildings; the Rain-gage below the top of the houſe, into which the greater quantity of Rain had for ſeveral years been found to fall, was above 15 feet above the level of the other Rain-gage, which in another part of London was placed above the top of the houſe, and into which the leſſer quantity always fell. This difference therefore does not, as Mr. Barrington juſtly remarks, depend upon the greater quantity of atmoſphere, through which the Rain deſcends: though this has been ſuppoſed by ſome, who have thence concluded that this appearance might readily be ſolved by the accumulation of more drops, in a deſcent through a great depth of atmoſphere."

RAINBOW, *Iris*, or ſimply the *Bow*, is a meteor in form of a party-coloured arch, or ſemicircle, exhibited in a rainy ſky, oppoſite to the ſun, by the refraction and reflection of his rays in the drops of falling rain. There is alſo a ſecondary, or fainter bow, uſually ſeen inveſting the former at ſome diſtance. Among naturaliſts, we alſo read of lunar Rainbows, marine Rainbows, &c.

The Rainbow, Sir Iſaac Newton obſerves, never appears but where it rains in the ſunſhine; and it may be repreſented artificially, by contriving water to fall

in ſmall drops, like rain, through which the ſun ſhining, exhibits a bow to a ſpectator placed between the ſun and the drops, eſpecially if there be diſpoſed beyond the drops ſome dark body, as a black cloth, or ſuch like.

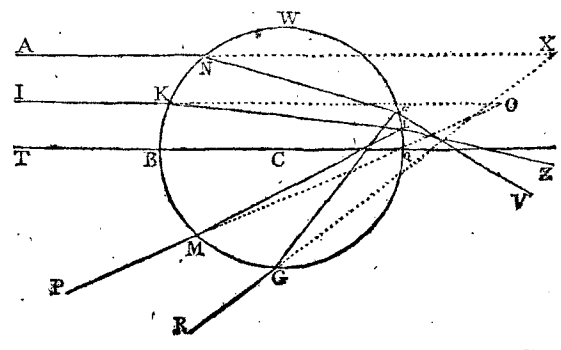
Some of the ancients, as appears by Ariſtotle's tract on Meteors, knew that the Rainbow was cauſed by the refraction of the ſun's light in drops of falling rain. Long afterwards, one Fletcher of Breſlaw, in a treatiſe which he publiſhed in 1571, endeavoured more particularly to account for the colours of the Rainbow by means of a double refraction, and one reflection. But he imagined that a ray of light, after entering a drop of rain, and ſuffering a refraction, both at its entrance and exit, was afterwards reflected from another drop, before it reached the eye of the ſpectator. It ſeems he overlooked the reflection at the farther ſide of the drop, or elſe he imagined that all the bendings of the light within the drop would not make a ſufficient curvature, to bring the ray of the ſun to the eye of the ſpectator. But Antonio de Dominis, biſhop of Spalato, about the year 1590, whoſe treatiſe *De Radiis Viſûs et Lucis* was publiſhed in 1611 by J. Bartolus, firſt advanced, that the double refraction of Fletcher, with an intervening reflection, was ſufficient to produce the colours of the Rainbow, and alſo to bring the rays that formed them to the eye of the ſpectator, without any ſubſequent reflection. He diſtinctly deſcribes the progreſs of a ray of light entering the upper part of the drop, where it ſuffers one refraction, and after being by that thrown upon the back part of the inner ſurface, is from thence reflected to the lower part of the drop; at which place undergoing a ſecond refraction, it is thereby bent ſo as to come directly to the eye. To verify this hypotheſis, he procured a ſmall globe of ſolid glaſs, and viewing it when it was expoſed to the rays of the ſun, in the ſame manner in which he had ſuppoſed the drops of rain were ſituated with reſpect to them, he actually obſerved the ſame colours which he had ſeen in the true Rainbow, and in the ſame order. Thus this author ſhewed how the interior bow is formed in round drops of rain, viz, by two refractions of the ſun's rays and one reflection between them; and he likewiſe ſhewed that the exterior bow is formed by two refractions and two ſorts of reflections between them in each drop of water.

The theory of A. de Dominis was adopted, and in ſome degree improved with reſpect to the exterior bow, by Des Cartes, in his treatiſe on Meteors; and indeed he was the firſt who, by applying mathematics to the inveſtigation of this ſurpriſing appearance, ever gave a tolerable theory of the Rainbow. Philoſophers were however ſtill at a loſs when they endeavoured to aſſign reaſons for all the particular colours, and for the order of them. Indeed nothing but the doctrine of the different refrangibility of the rays of light, a diſcovery which was reſerved for the great Newton, could furniſh a complete ſolution of this difficulty.

Dr. Barrow, in his Lectiones Opticæ, at Lect. 12, n. 14, ſays, that a friend of his (by whom we are to underſtand Mr. Newton) communicated to him a way of determining the angle of the Rainbow, which was hinted to Newton by Sluſius, without making a table of the refractions, as Des Cartes did. The doctor ſhews the method; as alſo ſeveral other matters, at n. 14, 15, 16, relating to the Rainbow, worthy the genius of thoſe two eminent men. But the ſubject was given more perfectly by Newton afterwards, viz, in his Optics, prop. 9; where he makes the breadth of the interior bow to be nearly 2° 15′, that of the exterior 3° 40′, their diſtance 8° 25′, the greateſt ſemidiameter of the interior bow 42° 17′, and the leaſt of the exterior 50° 42′, when their colours appear ſtrong and perfect.

The doctrine of the Rainbow may be illuſtrated and confirmed by experiment in ſeveral different ways. Thus, by hanging up a glaſs globe, full of water, in the ſun-ſhine, and viewing it in ſuch a poſture that the rays which come from the globe to the eye, may include an angle either of 42° or 50° with the ſun's rays; for ex. if the angle be about 42°, the ſpectator will ſee a full red colour in that ſide of the globe oppoſite to the ſun. And by varying the poſition ſo as to make that angle gradually leſs, the other colours, yellow, green, and blue, will appear ſucceſſively, in the ſame ſide of the globe, and that very bright. But if the angle be made about 50°, ſuppoſe by raiſing the globe, there will appear a red colour in that ſide of the globe toward the ſun, though ſomewhat faint; and if the angle be made greater, as by raiſing the globe ſtill higher, this red will change ſucceſſively to the other colours, yellow, green, and blue. And the ſame changes are obſerved by raiſing or depreſſing the eye, while the globe is at reſt. Newton's Optics, pt. 2, prop. 9, prob. 4.

Again, a ſimilar bow is often obſerved among the waves of the ſea (called the *marine Rainbow*), the upper parts of the waves being blown about by the wind, and ſo falling in drops. This appearance is alſo ſeen by moon light (called the *lunar Rainbow*), though ſeldom vivid enough to render the colours diſtinguiſhable. Alſo it is ſometimes ſeen on the ground, when the ſun ſhines on a very thick dew. Caſcades and fountains too, whoſe waters are in their fall divided into drops, exhibit Rainbows to a ſpectator, if properly ſituated during the time of the ſun's ſhining; and even water blown violently out of the mouth of an obſerver, ſtanding with his back to the ſun, never fails to produce the ſame phenomenon. The artificial Rainbow may even be produced by candle light on the water which is ejected by a ſmall fountain or jet d'eau. All theſe are of the ſame nature, and they depend upon the ſame cauſes; ſome account of which is as follows.



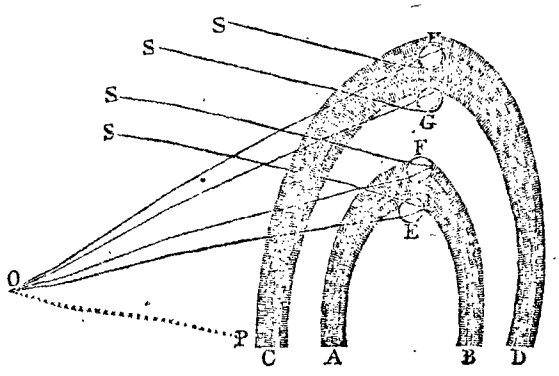
Let

Let the circle WQGB repreſent a drop of water, or a globe, upon which a beam of parallel light falls, of which let TB repreſent a ray falling perpendicularly at B, and which conſequently either paſſes through without refraction, or is reflected directly back from Q. Suppoſe another ray IK, incident at K, at a diſtance from B, and it will be refracted according to a certain ratio of the ſines of incidence and refraction to each other, which in rain water is as 529 to 396, to a point L, whence it will be in part tranſmitted in the direction L Z, and in part reflected to M, where it will again in part be reflected, and in part tranſmitted in the direction MP, being inclined to the line deſcribed by the incident ray in the angle IOP. Another ray AN, ſtill farther from B, and conſequently incident under a greater angle, will be refracted to a point F, ſtill farther from Q, whence it will be in part reflected to G, from which place it will in part emerge, forming an angle AXR with the incident AN, greater than that which was formed between the ray MP and its incident ray. And thus, while the angle of incidence, or diſtance of the point of incidence from B, increaſes, the diſtance between the point of reflection and Q, and the angle formed between the incident and emergent reflected rays, will alſo increaſe; that is, as far as it depends on the diſtance from B: but as the refraction of the ray tends to carry the point of reflection towards Q, and to diminiſh the angle formed between the incident and emergent reflected ray, and that the more the greater the diſtance of the point of incidence from B, there will be a certain point of incidence between B and W, with which the greateſt poſſible diſtance between the point of reflection and Q, and the greateſt poſſible angle between the incident and emergent reflected ray, will correſpond. So that a ray incident nearer to B ſhall, at its emergence after reflection, form a leſs angle with the incident, by reaſon of its more direct reflection from a point nearer to Q; and a ray incident nearer to W, ſhall at its emergence form a leſs angle with the incident, by reaſon of the greater quantity of the angles of refraction at its incidence and emergence. The rays which fall for a conſiderable ſpace in the vicinity of that point of incidence with which the greateſt angle of emergence correſponds, will, after emerging, form an angle with the incident rays differing inſenſibly from that greateſt angle, and conſequently will proceed nearly parallel to each other; and thoſe rays which fall at a diſtance from that point will emerge at various angles, and conſequently will diverge. Now, to a ſpectator, whoſe back is turned towards the radiant body, and whoſe eye is at a conſiderable diſtance from the globe or drop, the divergent light will be ſcarcely, if at all, perceptible; but if the globe be ſo ſituated, that thoſe rays that emerge parallel to each other, or at the greateſt poſſible angle with the incident, may arrive at the eye of the ſpectator, he will, by means of thoſe rays, behold it nearly with the ſame ſplendour at any diſtance.

In like manner, thoſe rays which fall parallel on a globe, and are emitted after two reflections, ſuppoſe at the points F and G, will emerge at H parallel to each oth when the angle they make with the incident AN is the leaſt poſſible; and the globe muſt be ſeen very reſplendent when its poſition is ſuch, that thoſe parallel rays fall on the eye of the ſpectator.

The quantities of theſe angles are determined by calculation, the proportion of the ſines of incidence and refraction to each other being known. And this proportion being different in rays which produce different colours, the angles muſt vary in each. Thus it is found, that the greateſt angle in rain water for the leaſt refrangible, or red rays, emitted parallel after one reflection, is 42° 2′, and for the moſt refrangible or violet rays, emitted parallel after one reflection, 40° 17′; likewiſe, after two reflections, the leaſt refrangible, or red rays, will be emitted nearly parallel under an angle of 50° 57′, and the moſt refrangible, or violet, under an angle of 54° 7′; and the intermediate colours will be emitted nearly parallel at intermediate angles.

Suppoſe now, that O is the ſpectator's eye, and OP a line drawn parallel to the ſun's rays, SE, SF, SG, and SH;



and let POE, POF, POG, POH be angles of 40° 17′, 42° 2′, 50° 57′, and 54° 7′ reſpectively; then theſe angles turned about their common ſide OP, will with their other ſides OE, OF, OG, OH deſcribe the verges of the two Rainbows, as in the figure. For, if E, F, G, H be drops placed any where in the conical ſuperficies deſcribed by OE, OF, OG, OH, and be illuminated by the ſun's rays SE, SF, SG, SH; the angle SEO being equal to the angle POE, or 40° 17′, will be the greateſt angle in which the moſt refrangible rays can, after one reflection, be refracted to the eye, and therefore all the drops in the line OE muſt ſend the moſt refrangible rays moſt copiouſly to the eye, and ſo ſtrike the ſenſe with the deepeſt violet colour in that region. In like manner, the angle SFO being equal to the angle POF, or 42° 2′, will be the greateſt in which the leaſt refrangible rays after one reflection can emerge out of the drops, and therefore thoſe rays muſt come moſt copiouſly to the eye from the drops in the line OF, and ſtrike the ſenſe with the deepeſt red colour in that region. And, by the ſame argument, the rays which have the intermediate degrees of refrangibility will come moſt copiouſly from drops between E and F, and ſtrike the ſenſes with the intermediate colours in the order which their degrees of refrangibility require; that is, in the

progreſs

progreſs from E to F, or from the inſide of the bow to the outſide, in this order, violet, indigo, blue, green, yellow, orange, red. But the violet, by the mixture of the white light of the clouds, will appear faint, and inclined to purple.

Again, the angle SGO being equal to the angle POG, or 50° 57′, will be the leaſt angle in which the leaſt refrangible rays can, after two reflections, emerge out of the drops, and therefore the leaſt refrangible rays muſt come moſt copiouſly to the eye from the drops in the line OG, and ſtrike the ſenſe with the deepeſt red in that region. And the angle SHO being equal to the angle POH, or 54° 7′, will be the leaſt angle in which the moſt refrangible rays, after two reflections, can emerge out of the drops, and therefore thoſe rays muſt come moſt copiouſly to the eye from the drops in the line OH, and ſtrike the ſenſe with the deepeſt violet in that region. And, by the ſame argument, the drops in the regions between G and H will ſtrike the ſenſe with the intermediate colours in the order which their degrees of refrangibility require; that is, in the progreſs from G to H, or from the inſide of the bow to the outſide, in this order, red, orange, yellow, green, blue, indigo, and violet. And ſince the four lines OE, OF, OG, OH may be ſituated any where in the above-mentioned conical ſuperficies, what is ſaid of the drops and colours in theſe lines, is to be underſtood of the drops and colours every where in thoſe ſuperficies.

Thus there will be made two bows of colours, an interior and ſtronger, by one reflection in the drops, and an exterior and fainter by two; for the light becomes fainter by every reflection; and their colours will lie in a contrary order to each other, the red of both bows bordering upon the ſpace GF, which is between the bows. The breadth of the interior bow, EOF, meaſured acroſs the colours, will be 1° 15′, and the breadth of the exterior GOH, will be 3° 10′, alſo the diſtance between them GOF, will be 8° 55′, the greateſt ſemidiameter of the innermoſt, that is, the angle POF, being 42° 2′, and the leaſt ſemidiameter of the outermoſt FOG being 50° 57′. Theſe are the meaſures of the bows as they would be, were the ſun but a point; but by the breadth of his body, the breadth of the bows will be increaſed by half a degree, and their diſtance diminiſhed by as much; ſo that the breadth of the inner bow will be 2° 15′, that of the outer 3° 40′, their diſtance 8° 25′; the greateſt ſemidiameter of the interior bow 42° 17′, and the leaſt of the exterior 50° 42′. And ſuch are the dimenſions of the bows in the heavens found to be, very nearly, when their colours appear ſtrong and perfect.

The light which comes through drops of rain by two refractions without any reflection, ought to appear ſtrongeſt at the diſtance of about 26 degrees from the ſun, and to decay gradually both ways as the diſtance from the ſun increaſes and decreaſes. And the ſame is to be underſtood of light tranſmitted through ſpherical hailſtones. If the hail be a little flatted, as it often is, the light tranſmitted may grow ſo ſtrong at a little leſs diſtance than that of 26°, as to form a halo about the ſun and moon; which halo, when the ſtones are duly figured, may be coloured, and then it muſt be red within, by the leaſt refrangible rays, and blue without, by the moſt refrangible ones.

The light which paſſes through a drop of rain after two refractions, and three or more reflections, is ſcarce ſtrong enough to cauſe a ſenſible bow.

As to the dimenſion of the Rainbow, Des Cartes firſt determined its diameter by a tentative and indirect method; laying it down, that the magnitude of the bow depends on the degree of refraction of the fluid; and aſſuming the ratio of the ſine of incidence to that of refraction, to be in water as 250 to 187. But Dr. Halley, in the Philoſ. Tranſ. number 267, gave a ſimple direct method of determining the diameter of the Rainbow from the ratio of the refraction of the fluid being given; or, vice verſa, the diameter of the Rainbow being given, to determinethe refractive power of the fluid. And Dr. Halley's principles and conſtruction were farther explained by Dr. Morgan, biſhop of Ely, in his Diſſertation on the Rainbow, among the notes upon Rohault's Syſtem of Philoſophy, part 3, chap. 17.

From the theory of the Rainbow, all the particular phenomena of it are eaſily deducible. Hence we ſee, 1ſt, Why the iris is always of the ſame breadth; becauſe the intermediate degrees of refrangibility of the rays between red and violet, which are its extreme colours, are always the ſame.

2dly, Why the bow ſhifts its ſituation as the eye does; and, as the popular phraſe has it, flies from thoſe who follow it, and follows thoſe that fly from it; the coloured drops being diſpoſed under a certain angle, about the axis of viſion, which is different in different places: whence alſo it follows, that every different ſpectator ſees a different bow.

3dly, Why the bow is ſometimes a larger portion of a circle, ſometimes a leſs: its magnitude depending on the greater or leſs part of the ſurface of the cone, above the ſurface of the earth, at the time of its appearance; and the higher the ſun, always the leſs the Rainbow.

4thly, Why the bow never appears when the ſun is above a certain altitude; the ſurface of the cone, in which it ſhould be ſeen, being loſt in the ground at a little diſtance from the eye, when the ſun is above 42° high.

5thly, Why the bow never appears greater than a ſemicircle, on a plane; ſince, be the ſun never ſo low, and even in the horizon, the centre of the bow is ſtill in the line of aſpect; which in this caſe runs along the earth, and is not at all raiſed above the ſurface. Indeed if the ſpectator be placed on a very conſiderable eminence, and the ſun in the horizon, the line of aſpect, in which the centre of the bow is, will be conſiderably raiſed above the horizon. And if the eminence be very high, and the rain near, it is poſſible the bow may be an entire circle.

6thly, How the bow may chance to appear inverted, or the concave ſide turned upwards; viz, a cloud happening to intercept the rays, and prevent their ſhining on the upper part of the arch: in which caſe, only the lower part appearing, the bow will ſeem as if turned upſide down; which has probably been the caſe in ſeveral prodigies of this kind, related by authors.

Lunar

Lunar RAINBOW. The moon ſometimes alſo exhibits the phenomenon of an iris, by the refraction of her rays in the drops of rain in the night-time.

Ariſtotle ſays, he was the firſt that ever obſerved it; nd adds, it is never ſeen but at the time of the ull moon; her light at other times being too aint to affect the ſight after two refractions and one reflection.

The lunar iris has all the colours of the ſolar, very diſtinct and pleaſant; only fainter, both from the different intenſity of the rays, and the different diſpoſition of the medium.

Marine RAINBOW. This is a phenomenon ſometimes obſerved in a much agitated ſea; when the wind, ſweeping part of the tops of the waves, carries them aloft; ſo that the ſun's rays, falling upon them, are refracted, &c, as in a common ſhower, and there paint the colours of the bow. Theſe bows are leſs diſtinguiſhable and bright than the common bow: but then they exceed as to numbers, there being ſometimes 20 or 30 ſeen together. They appear at noon day, and in a poſition oppoſite to that of the common bow, the concave ſide being turned upwards, as indeed it ought to be.

RAIN-GAGE, an inſtrument for meaſuring the quantity of rain that falls. It is the ſame as OMBROMETER, or PLUVIAMETER, which ſee.

RAKED *Table*, or RAKING *Table*, in Architecture, a member hollowed in the ſquare of a pedeſtal, or elſewhere.

RAM, in Aſtronomy. See ARIES.

RAM, *battering*. See BATTERING *Ram*.

RAMS-HORNS, in Fortification, a name given by Belidor to the Tenailles.

RAMPART, or RAMPIER, in Fortification, a maſſy bank or elevation of earth around a place, to cover it from the direct fire of an enemy, and of ſufficient thickneſs to reſiſt the efforts of their cannon for many days. It is formed into baſtions, curtains, &c.

Upon the Rampart the ſoldiers continually keep guard, and the pieces of artillery are planted for defence. Alſo, to ſhelter the men from the enemy's ſhot, the outſide of the Rampart is built higher than the reſt, i. e. a parapet is raiſed upon it with a platform. It is encompaſſed with a moat or ditch, out of which is dug the earth that forms the Rampart, which is raiſed ſloping, that the earth may not ſlip down, and having a berme at bottom, or is otherwiſe fortified, being lined with a facing of brick or ſtone.

The height of the Rampart need not be more than 3 fathoms, this being ſufficient to cover the houſes from the battery of the cannon; neither need its thickneſs be more than 10 or 12, unleſs more earth come out of the ditch than can otherwiſe be beſtowed.

The Ramparts of halfmoons are the better for being low, that the ſmall fire of the defendants may the better reach the bottom of the ditch; but yet they muſt be ſo high as not to be commanded by the covert-way.

RAMPART is alſo uſed, in civil architecture, for the void ſpace left between the wall of a city and the houſes. This is what the Romans called Pomœrium, where it was forbidden to build, and where they planted rows of trees for the people to walk and amuſe themſelves under.

RAMUS (PETER), a celebrated French mathematician and philoſopher, was born in 1515, in a village of Vermandois in Picardy. He was deſcended of a good family, which had been reduced to extreme poverty by the wars and other misfortunes. His own life too, ſays Bayle, was the ſport of fortune. In his infancy he was twice attacked by the plague. At 8 years of age, a thirſt for learning urged him to go to Paris; but he was ſoon forced by poverty to leave that city. He returned to it again as ſoon as he could; but, being unable to ſupport himſelf, he left it a ſecond time: yet his paſſion for ſtudy was ſo violent, that notwithſtanding his bad ſucceſs in the two former viſits, he ventured upon a third. He was maintained there ſome months by one of his uncles; after which he was obliged to become a ſervant in the college of Navarre. Here he ſpent the day in waiting upon his maſters, and the greateſt part of the night in ſtudy.

After having finiſhed claſſical learning and rhetoric, he went through a courſe of philoſophy, which took him up three years and a half in the ſchools. The theſis, which he made for his maſter of arts degree, offended every one; for he maintained in it, that all that Ariſtotle had advanced was falſe; and he gave very good anſwers to the objections of the profeſſors. This ſucceſs encouraged him to examine the doctrine of Ariſtotle more cloſely, and to combat it vigorouſly: but he confined himſelf chiefly to his logic. The two firſt books he publiſhed, the one entitled, *Inſtitutiones Dialecticæ*, the other *Ariſtotelicæ Animadverſiones*, occaſioned great diſturbances in the univerſity of Paris. The profeſſors there, who were adorers of Ariſtotle, ought to have refuted Ramus's books, if they could, by writings and lectures: but inſtead of confining themſelves within the juſt bounds of academical wars, they proſecuted this anti-peripatetic before the civil magiſtrate, as a man who was going to ſap the foundations of religion. They raiſed ſuch clamours, that the cauſe was carried before the parliament of Paris: but, perceiving that it would be examined equably, his enemies by their intrigues took it from that tribunal, to bring it before the king's council, in 1543. The king ordered, that Ramus and Anthony Govea, who was his principal adverſary, ſhould chooſe two judges each, to pronounce on the controverſy, after they ſhould have ended their diſputation; while he himſelf appointed a deputy. Ramus appeared before the five judges, though three of them were his declared enemies. The diſpute laſted two days, and Govea had all the advantages he could deſire; Ramus's books being prohibited in all parts of the kingdom, and their author ſentenced not to teach philoſophy any longer; upon which his enemies triumphed in the moſt indecent manner.

The year after, the plague made great havoc in Paris, and forced moſt of the ſtudents in the college of Preſle to quit it; but Ramus, being prevailed upon to teach in it, ſoon drew together a great number of auditors. The Sorbonne attempted in vain to drive him from that college; for he held the headſhip of that houſe

houſe by arrêt of parliament. Through the patronage and protection of the cardinal of Lorrain, he obtained from Henry the 2d, in 1547, the liberty of ſpeaking and writing, and the regal profeſſorſhip of philoſophy and eloquence in 1551. The parliament of Paris had, before this, maintained him in the liberty of joining philoſophical lectures to thoſe of eloquence; and this arrêt or decree had put an end to ſeveral proſecutions, which Ramus and his pupils had ſuffered. As ſoon as he was made regius profeſſor, he was fired with a new zeal for improving the ſciences, notwithſtanding the hatred of his enemies, who were never at reſt.

Ramus bore at that time a part in a very ſingular affair. About the year 1550, the royal profeſſors corrected among other abuſes, that which had crept into the pronunciation of the Latin tongue. Some of the clergy followed this regulation; but the Sorbonniſts were much offended at it as an innovation, and defended the old pronunciation with great zeal. Things at length were carried ſo far, that a miniſter, who had a good living, was very ill treated by them; and cauſed to be ejected from his benefice for having pronounced *guiſquis*, *quanquam*, according to the new way, inſtead of *kiſkis*, *kankam*, according to the old. The miniſter applied to the parliament; and the royal profeſſors, with Ramus among them, fearing he would fall a victim to the credit and authority of the faculty of divines, for preſuming to pronounce the Latin tongue according to their regulations, thought it incumbent on them to aſſiſt him. Accordingly, they went to the court of juſtice, and repreſented in ſuch ſtrong terms the indignity of the proſecution, that the miniſter was cleared, and every perſon had the liberty of pronouncing as he pleaſed.

Ramus was bred up in the Catholic religion, but afterwards deſerted it. He began to diſcover his new principles by removing the images from the chapel of his college of Preſle, in 1552. Hereupon ſuch a perſecution was raiſed againſt him by the Religioniſts, as well as Ariſtotelians, that he was driven out of his profeſſorſhip, and obliged to conceal himſelf. For that purpoſe, with the king's leave he went to Fontainbleau; where, by the help of books in the king's library, he proſecuted geometrical and aſtronomical ſtudies. As ſoon as his enemies found out his retreat, they renewed their perſecutions; and he was forced to conceal himſelf in ſeveral other places. In the mean time, his curious and excellent collection of books in the college of Preſle was plundered: but after a peace was concluded in 1563, between Charles the 9th and the Proteſtants, he again took poſſeſſion of his employment, maintained himſelf in it with vigour, and was particularly zealous in promoting the ſtudy of the mathematics.

This continued till the ſecond civil war in 1567, when he was forced to leave Paris, and ſhelter himſelf among the Hugonots, in whoſe army he was at the battle of St. Denys. Peace having been concluded ſome months after, he was reſtored to his profeſſorſhip; but, foreſeeing that the war would ſoon break out again, he did not care to venture himſelf in a freſh ſtorm, and therefore obtained the king's leave to viſit the univerſities of Germany. He accordingly undertook this journey in 1568, and received great honours wherever he came. He returned to France, after the third war in 1571; and loſt his life miſerably, in the maſſacre of St. Bartholomew's day, 1572, at 57 years of age. It is ſaid, that he was concealed in a granary during the tumult; but diſcovered and dragged out by ſome peripatetic doctors who hated him; theſe, after ſtripping him of all his money under pretence of preſerving his life, gave him up to the aſſaſſins, who, after cutting his throat and giving him many wounds, threw him out of the window; and his bowels guſhing out in the fall, ſome Ariſtotelian ſcholars, encouraged by their maſters, ſpread them about the ſtreets; then dragged his body in a moſt ignominious manner, and threw it into the river.

Ramus was a great orator, a man of univerſal learning, and endowed with very fine qualities. He was ſober, temperate, and chaſte. He ate but little, and that of boiled meat; and drank no wine till the latter part of his life, when it was preſcribed by the phyſicians. He lay upon ſtraw; roſe early, and ſtudied hard all day; and led a ſingle life with the utmoſt purity. He was zealous for the proteſtant religion, but at the ſame time a little obſtinate, and given to contradiction. The proteſtant miniſters did not love him much, for he made himſelf a kind of head of a party, to change the diſcipline of the proteſtant churches: his deſign was to introduce a democratical government in the church, but this deſign was traverſed, and defeated in a national ſynod. His ſect flouriſhed however for ſome time afterwards, ſpreading pretty much in Scotland and England, and ſtill more in Germany.

He publiſhed a great many books; but mathematics was chiefly obliged to him. Of this kind, his writings were principally theſe following:

1. *Scholarum Mathematicarum libri* 31.

2. *Arithmeticæ libri duo.—Algebræ libri duo.—Geometriæ libri* 27.

Theſe were greatly enlarged and explained by Schoner, and publiſhed in 2 volumes 4to. There were ſeveral editions of them; mine is that of 1627, at Frankfort.—The Geometry, which is chiefly practical, was tranſlated into Engliſh by William Bedwell, and publiſhed in 4to, at London, 1636.

RANDOM-SHOT, is a ſhot diſcharged with the axis of the gun elevated above the horizontal or point-blank direction.

RANDOM, of a ſhot, alſo ſometimes means the range of it, or the diſtance to which it goes at the firſt graze, or where it ſtrikes the ground. See RANGE.

RANGE, in Gunnery, ſometimes means the path a ſhot flies in. But more uſually,

RANGE now means the diſtance to which the ſhot flies when it ſtrikes the ground or other object, called alſo the amplitude of the ſhot. But Range is the term in preſent uſe.

Were it not for the reſiſtance of the air, the greateſt Range, on a horizontal plane, would be when the ſhot is diſcharged at an angle of 45° above the horizon; and all other Ranges would be the leſs, the more the angle of elevation is above or below 45°; but ſo as that at equal diſtances above and below 45°, the two Ranges are equal to each other. But, on account of the reſiſtance of the air, the Ranges are altered, and that in different proportions, both for the different

ſizes

ſizes of the ſhot, and their different velocities: ſo that the greateſt Range, in practice, always lies below the elevation of 45°, and the more below it as the ſhot is ſmaller, and as its velocity is greater; ſo as that the ſmalleſt balls, diſcharged with the greateſt velocity in practice, ranges the fartheſt with an elevation of 30° or under, while the largeſt ſhot, with very ſmall velocities, range fartheſt with nearly 45° elevation; and at all the intermediate degrees in the other caſes. See PROJECTILES.

RARE, in Phyſics, is the quality of a body that is very porous, whoſe parts are at a great diſtance from one another, and which contains but little matter under a great magnitude. In which ſenſe Rare ſtands oppoſed to denſe.

The corpuſcular philoſophers, viz, the Epicureans, Gaſſendiſts, Newtonians, &c, aſſert that bodies are rarer, ſome than others, in virtue of a greater quantity of pores, or of vacuity lying between their parts or particles. The Carteſians hold, that a greater rarity only conſiſts in a greater quantity of materia ſubtilis contained in the pores. And laſtly, the Peripatetics contend, that rarity is a new quality ſuperinduced upon a body, without any dependence on either vacuity or ſubtile matter.

RAREFACTION, in Phyſics, the rendering a body rarer, that is bringing it to expand or occupy more room or ſpace, without the acceſſion of new matter: and it is oppoſed to condenſation. The more accurate writers reſtrict the term Rarefaction to that kind of expanſion which is effected by means of heat: and the expanſion from other cauſes they term *dilatation*; if indeed there be other cauſes; for though ſome philoſophers have attributed it to the action of a repulſive principle in the matter itſelf; yet from the many diſcoveries concerning the nature and properties of the electric fluid and fire, there is great reaſon to believe that this repulſive principle is no other than elementary fire.

The Carteſians deny any ſuch thing as abſolute Rarefaction: extenſion, according to them, conſtituting the eſſence of matter, they are obliged to hold all extenſion equally full. Hence they make Rarefaction to be no other than an acceſſion of freſh, ſubtile, and inſenſible matter, which, entering the parts of bodies, ſenſibly diſtends them.

It is by Rarefaction that gunpowder has its effect; and to the ſame principle alſo we owe eolipiles, thermometers, &c. As to the air, the degree to which it is rarefiable exceeds all imagination, experience having ſhewn it to be far above 10,000 times more than the uſual ſtate of the atmoſphere; and as it is found to be about 1000 times denſer in gunpowder than the atmoſphere, it follows that experience has found it differ by about 10 millions of times. Perhaps indeed its degree of expanſion is abſolutely beyond all limits.

Such immenſe Rarefaction, Newton obſerves, is inconceivable on any other principle than that of a repelling force inherent in the air, by which its particles mutually fly from one another. This repelling force, he obſerves, is much more conſiderable in air than in other bodies, as being generated from the moſt fixed bodies, and that with much difficulty, and ſcarce without fermentation; thoſe particles being always found to fly from each other with the greateſt force, which, when in contact, cohere the moſt firmly together. See AIR.

Upon the Rarefaction of the air is founded the uſeful method of meaſuring altitudes by the barometer, in all the caſes of which, the rarity of the air is found to be inverſely as the force that compreſſes it, or inverſely as the weight of all the air above it at any place.

RARITY, thinneſs, ſubtlety, or the contrary to denſity.

RATCH, or RASH, in Clock-Work, a ſort of wheel having 12 fangs, which ſerve to lift up the detents every hour, to make the clock ſtrike.

RATCHETS, in a Watch, are the ſmall teeth at the bottom of the fuſee, or barrel, that ſtop it in winding up.

RATIO, according to Euclid, is the habitude or relation of two magnitudes of the ſame kind in reſpect of quantity. So the ratio of 2 to 1 is double, that of 3 to 1 triple, &c. Several mathematicians have found fault with Euclid's definition of a Ratio, and others have as much defended it, eſpecially Dr. Barrow, in his Mathematical Lectures, with great ſkill and learning.

Ratio is ſometimes confounded with proportion, but very improperly, as being quite different things; for proportion is the ſimilitude or equality or identity of two Ratios. So the Ratio of 6 to 2 is the ſame as that of 3 to 1, and the Ratio of 15 to 5 is that of 3 to 1 alſo; and therefore the Ratio of 6 to 2 is ſimilar or equal or the ſame with that of 15 to 5, which conſtitutes proportion, which is thus expreſſed, 6 is to 2 as 15 to 5, or thus 6 : 2 :: 15 : 5, which means the ſame thing. So that Ratio exiſts between two terms, but proportion between two Ratios or four terms.

The two quantities that are compared, are called the *terms* of the Ratio, as 6 and 2; the firſt of theſe 6 being called the *antecedent*, and the latter 2 the *conſequent*. Alſo the *index* or *exponent* of the Ratio, is the quotient of the two terms: ſo the index of the Ratio of 6 to 2 is $\frac{6}{2}$ or 3, and which is therefore called a *triple Ratio*.

Wolfius diſtinguiſhes Ratios into *rational* and *irrational*.

Rational RATIO is that which can be expreſſed between two rational numbers; as the Ratio of 6 to 2, or of $6\sqrt{3}$ to $2\sqrt{3}$, 3 to 1. And

Irrational RATIO is that which cannot be expreſſed by that of one rational number to another; as the Ratio of $\sqrt{6}$ to $\sqrt{2}$, or of $\sqrt{3}$ to root $\sqrt{1}$, that is $\sqrt{3}$ to 1, which cannot be expreſſed in rational numbers.

When the two terms of a Ratio are equal, the Ratio is ſaid to be that of *equality*; as of 3 to 3, whoſe index is 1, denoting the ſingle or equal Ratio. But when the terms are not equal, as of 6 to 2, it is a *Ratio of inequality*.

Farther, when the antecedent is the greater term, as in 6 to 2, it is ſaid to be the *Ratio of greater inequality*: but when the antecedent is the leſs term, as in the Ratio of 2 to 6, it is ſaid to be the *Ratio of leſs*

leſs inequality. In the former caſe, if the leſs term be an aliquot part of the greater, the Ratio of greater inequality is ſaid to be *multiplex* or *multiple;* and the Ratio of the leſs inequality, *ſub-multiple.* Particularly, in the firſt caſe, if the exponent of the Ratio be 2, as in 6 to 3, the Ratio is called *duple* or *double;* if 3, as in 6 to 2, it is *triple;* and ſo on. In the ſecond caſe, if the Ratio be $\frac{1}{2}$, as in 3 to 6, the Ratio is called *ſubduple;* if $\frac{1}{3}$, as in 2 to 6, it is *ſubtriple;* and ſo on.

If the greater term contain the leſs once, and one aliquot part of the ſame over; the Ratio of the greater inequality is called *ſuperparticular*, and the Ratio of the leſs *ſubſuperparticular.* Particularly, in the firſt caſe, if the exponent be $\frac{3}{2}$ or $1\frac{1}{2}$, it is called *ſeſquialterate;* if $\frac{4}{3}$ or $1\frac{1}{3}$, *ſeſquitertial;* &c. In the other caſe, if the exponent be $\frac{3}{4}$, the Ratio is called *ſubſeſquialterate;* if $\frac{4}{3}$, it is *ſubſeſquitertial.*

When the greater term contains the leſs once and ſeveral aliquot parts over, the Ratio of the greater inequality is called *ſuperpartiens*, and that of the leſs inequality is *ſubſuperpartiens.* Particularly, in the former caſe, if the exponent be $\frac{5}{3}$ or $1\frac{2}{3}$, the Ratio is called *ſuperbipartiens tertias;* if the exponent be $\frac{7}{4}$ or $1\frac{3}{4}$, *ſupertripartiens quartas;* if $\frac{11}{7}$ or $1\frac{4}{7}$, *ſuperquadripartiens ſeptimas;* &c. In the latter caſe, if the exponent be the reciprocals of the former, or $\frac{3}{5}$, the Ratio is called *ſubſuperbipartiens tertias;* if $\frac{4}{7}$, *ſubſupertripartiens quartas;* if $\frac{7}{11}$, *ſubſuperquadripartiens ſeptimas;* &c.

When the greater term contains the leſs ſeveral times, and ſome one part over; the ratio of the greater inequality is called *multiplex ſuperparticular*; and the Ratio of the leſs inequality is called *ſubmultiplex ſubſuperparticular.* Particularly, in the former caſe, if the exponent be $\frac{5}{2}$ or $2\frac{1}{2}$, the ratio is called *dupla ſeſquialtera*; if $\frac{13}{4}$ or $3\frac{1}{4}$, *tripla ſeſquiquarta*, &c. In the latter caſe, if the exponent be $\frac{2}{5}$, the Ratio is called *ſubdupla ſubſeſquialtera*; if $\frac{4}{13}$, *ſubtripla ſubſeſquiquarta*, &c. Laſtly, when the greater term contains the leſs ſeveral times, and ſeveral aliquot parts over; the Ratio of the greater inequality is called *multiplex ſuperpartiens*; that of the leſs inequality, *ſubmultiplex ſubſuperpartiens.* Particularly, in the former caſe, if the exponent be $\frac{8}{3}$ or $2\frac{2}{3}$, the Ratio is called *dupla ſuperbipartiens tertias*; if $\frac{25}{7}$ or $3\frac{4}{7}$, *tripla ſuperbiquadripartiens ſeptimas*, &c. In the latter caſe, if the exponent be $\frac{3}{8}$, the Ratio is called *ſubdupla ſubſuperbipartiens tertias*; if $\frac{7}{25}$, *ſubtripla ſubſuperquadripartiens ſeptimas*; &c.

Theſe are the various denominations of rational Ratios, names which are very neceſſary to the reading of the ancient authors; though they occur but rarely among the modern writers, who uſe inſtead of them the ſmalleſt numeral terms of the Ratios; ſuch 2 to 1 for duple, and 3 to 2 for ſeſquialterate, &c.

Compound RATIO, is that which is made up of two or more other Ratios, viz. by multiplying the exponents together, and ſo producing the compound Ratio of the product of all the antecedents to the product of all the conſequents.

Thus the compound Ratio of 5 to 3,
and 7 to 4,
is the Ratio of - - - - 35 to 12.

Particularly, if a Ratio be compounded of two equal Ratios, it is called the *duplicate Ratio*; if of three equal Ratios, the *triplicate Ratio*; if of four equal Ratios, the *quadruplicate Ratio*; and ſo on, according to the powers of the exponents, for all *multiplicate Ratios.* So the ſeveral multiplicate Ratios of

the ſimple Ratio of - 3 to 2, are thus, viz.
the duplicate Ratio - 9 : 4,
the triplicate Ratio - 27 : 8,
the quadruplicate Ratio 81 : 16, &c.

Properties of RATIOS. Some of the more remarkable properties of Ratios are as follow:

1. The like multiples, or the like parts, of the terms of a Ratio, have the ſame Ratio as the terms themſelves. So $a : b$, and $na : nb$, and $\frac{a}{n} : \frac{b}{n}$ are all the ſame Ratio.

2. If to, or from, the terms of any Ratio, be added or ſubtracted either their like parts, or their like multiples, the ſums or remainders will ſtill have the ſame Ratio. So $a : b$, and $a \pm na : b \pm nb$, and $a \pm \frac{a}{n} : b \pm \frac{b}{n}$ are all the ſame Ratio.

3. When there are ſeveral quantities in the ſame continued Ratio, a, b, c, d, e, &c. whatever Ratio the firſt has to the 2d,
the 1ſt to the 3d has the duplicate of that Ratio,
the 1ſt to the 4th has the triplicate of that Ratio,
the 1ſt to the 5th has the quadruplicate of it,
and ſo on. Thus, the terms of the continued Ratio being $1, r, r^2, r^3, r^4, r^5$, &c, where each term has to the following one the Ratio of 1 to r, the Ratio of the 1ſt to the 2d; then $1 : r^2$ is the duplicate, $1 : r^3$ the triplicate, $1 : r^4$ the quadruplicate, and ſo on, according to the powers of $1 : r$.

For other properties ſee PROPORTION.

To approximate to a RATIO *in ſmaller Terms.*—Dr. Wallis, in a ſmall tract at the end of Horrox's works, treats of the nature and ſolution of this problem, but in a very tedious way; and he has proſecuted the ſame to a great length in his Algebra, chap. 10 and 11, where he particularly applies it to the Ratio of the diameter of a circle to its circumference. Mr. Huygens too has given a ſolution, with the reaſons of it, in a much ſhorter and more natural way, in his Deſcrip. Autom. Planet. Opera Reliqua, vol. 1, pa. 174.

So alſo has Mr. Cotes, at the beginning of his Harmon. Menſurarum. And ſeveral other perſons have done the ſame thing, by the ſame or ſimilar methods. The problem is very uſeful, for expreſſing a Ratio in ſmall numbers, that ſhall be near enough in practice, to any given Ratio in large numbers, ſuch as that of the diameter of a circle to its circumference. The principle of all theſe methods, conſiſts in reducing the terms of the propoſed Ratio into a ſeries of what are called continued fractions, by dividing the greater term by the leſs, and the leſs by the remainder, and ſo on, always the laſt diviſor by the laſt remainder, after the manner of finding the greateſt common meaſure of the two terms; then connecting all the quotients &c together in a ſeries of continued fractions; and laſtly collecting gradually theſe fractions together one after another.

So if $\frac{b}{a}$ be any fraction, or exponent of any Ratio; then dividing thus,

a) b (c

$$a)\overline{b}\,(c$$
$$d)\overline{a}\,(e$$
$$f)\overline{d}\,(g$$
$$h)\overline{f}\,(i$$
$$k)\overline{h}\,(l$$
&c.

gives c, e, g, i, &c, for the ſeveral quotients, and theſe, formed in the uſual way, give the approximate value of the given Ratio in a ſeries of continued fractions; thus,

$$\frac{b}{a} = c + \frac{1}{e} + \frac{1}{g} + \frac{1}{i} + \text{ &c.}$$

Then collecting the terms of this ſeries, one after another, ſo many values of $\frac{b}{a}$ are obtained, always nearer and nearer; the firſt value being c or $\frac{c}{1}$, the next

$$c + \frac{1}{e} = \frac{ce+1}{e} = \frac{A}{B},$$

the 3d value $c + \frac{1}{e} + \frac{1}{g} = c + \frac{1}{\frac{ge+1}{g}} = c + \frac{g}{ge+1} =$

$$\frac{cge + c + g}{ge+1} = \frac{(ce+1)g + c}{ge+1} = \frac{Ag + c}{Bg+1} = \frac{C}{D};$$

in like manner,

the 4th value is $\frac{Ci + A}{Di + B} = \frac{E}{F}$;

the 5th value is $\frac{El + C}{Fl + D} = \frac{G}{H}$; &c.

From whence comes this general rule: Having found any two of theſe values, multiply the terms of the latter of them by the next quotient, and to the two products add the correſponding terms of the former value, and the ſums will be the terms of the next value, &c.

For example, let it be required to find a ſeries of Ratios in leſſer numbers, conſtantly approaching to the Ratio of 100000 to 314159, or nearly the Ratio of the diameter of a circle to its circumference. Here firſt dividing, thus,

$$100000)\overline{314159}\,(3 = c$$
$$d = 14159)\overline{100000}\,(7 = e$$
$$f = 887)\overline{14159}\,(15 = g$$
$$h = 854)\overline{887}\,(1 = i, \text{ &c.}$$
&c.

there are obtained the quotients 3, 7, 15, 1, 25, 1, 7, 4.

Hence 3 or $\frac{3}{1} = c$, the 1ſt value;

$\frac{ce+1}{e} = \frac{3.7+1}{1.7} = \frac{22}{7} = \frac{A}{B}$, the 2d value;

$\frac{Ag+c}{Bg+1} = \frac{22.15+3}{7.15+1} = \frac{333}{106} = \frac{C}{D}$, the 3d value;

$\frac{Ci+A}{Di+B} = \frac{333.1+22}{106.1+7} = \frac{355}{113} = \frac{E}{F}$, the 4th value; and ſo on; where the ſucceſſive continual approximating values of the propoſed Ratio are $\frac{3}{1}$, $\frac{22}{7}$, $\frac{333}{106}$, $\frac{355}{113}$, &c; the 2d of theſe, viz. $\frac{22}{7}$, being the approximation of Archimedes; and the 4th, viz $\frac{355}{133}$, is that of Metius, which is very near the truth, being equal to 3·1415929, the more accurate Ratio being - - 3·1415927.

The doctrine of Ratios and Proportions, as delivered by Euclid, in the fifth book of his Elements, is conſidered by moſt perſons as very obſcure and objectionable, particularly the definition of proportionality; and ſeveral ingenious gentlemen have endeavoured to elucidate that ſubject. Among theſe, the Rev. Mr. Abram Robertſon, of Chriſt Church College, Oxford, lecturer in geometry in that univerſity, printed a neat little paper there in 1789, for the uſe of his claſſes, being a demonſtration of that definition, in 7 propoſitions, the ſubſtance of which is as follows. He firſt premiſes this advertiſement:

"As demonſtrations depending upon proportionality pervade every branch of mathematical ſcience, it is a matter of the higheſt importance to eſtabliſh it upon clear and indiſputable principles. Moſt mathematicians, both ancient and modern, have been of opinion that Euclid has fallen ſhort of his uſual perſpicuity in this particular. Some have queſtioned the truth of the definition upon which he has founded it, and, almoſt all who have admitted its truth and validity have objected to it *as a definition*. The author of the following propoſitions ranks himſelf amongſt objectors of the laſt mentioned deſcription. He thinks that Euclid muſt have founded the definition in queſtion upon the reaſoning contained in the firſt ſix demonſtrations here given, or upon a ſimilar train of thinking; and in his opinion *a definition* ought to be as ſimple, or as free from a multiplicity of conditions, as the ſubject will admit."

He then lays down theſe four definitions:

"1. Ratio is the relation which one magnitude has to another, of the ſame kind, with reſpect to quantity."

"2. If the firſt of four magnitudes be exactly as great when compared to the ſecond, as the third is when compared to the fourth, the firſt is ſaid to have to the ſecond the ſame Ratio that the third has to the fourth."

"3. If the firſt of four magnitudes be greater, when compared to the ſecond, than the third is when compared to the fourth, the firſt is ſaid to have to the ſecond a greater Ratio than the third has to the fourth."

"4. If the firſt of four magnitudes be leſs, when compared to the ſecond, than the third is when compared to the fourth, the firſt is ſaid to have to the ſecond a leſs Ratio than the third has to the fourth."

Mr. Robertſon then delivers the propoſitions, which are the following:

"*Prop.* 1. If the firſt of four magnitudes have to the ſecond, the ſame Ratio which the third has to the fourth;

then, if the firſt be equal to the ſecond, the third is equal to the fourth; if greater, greater; if leſs, leſs."

"*Prop.* 2. If the firſt of four magnitudes be to the ſecond as the third to the fourth, and if any equimultiples whatever of the firſt and third be taken, and alſo any equimultiples of the ſecond and fourth; the multiple of the firſt will be to the multiple of the ſecond as the multiple of the third to the multiple of the fourth."

"*Prop.* 3. If the firſt of four magnitudes be to the ſecond as the third to the fourth, and if any like aliquot parts whatever be taken of the firſt and third, and any like aliquot parts whatever of the ſecond and fourth, the part of the firſt will be to the part of the ſecond as the part of the third to the part of the fourth."

"*Prop.* 4. If the firſt of four magnitudes be to the ſecond as the third to the fourth, and if any equimultiples whatever be taken of the firſt and third, and any whatever of the ſecond and fourth; if the multiple of the firſt be equal to the multiple of the ſecond, the multiple of the third will be equal to the multiple of the fourth; if greater, greater; if leſs, leſs."

"*Prop.* 5. If the firſt of four magnitudes be to the ſecond as the third is to a magnitude leſs than the fourth, then it is poſſible to take certain equimultiples of the firſt and third, and certain equimultiples of the ſecond and fourth, ſuch, that the multiple of the firſt ſhall be greater than the multiple of the ſecond, but the multiple of the third not greater than the multiple of the fourth."
